Have you for some years past suffered from asthmatic or quasi-asthmatic trouble?—Yes, for five or six years past at least.

What has been the nature of your attacks?—Very violent attacks of breathlessness.

Does it come on in the day or in the night time?—Principally in the day; it never comes on at night; it comes on in the daytime, and never when I am at rest, and I think that is what distinguishes it from true asthma.

It does not come on when you are lying down but when you are up in the day?—Yes.

During those years have you had almost constant trouble with it?—Constantly in bad weather, yes.

Have you tried many treatments?—A good number of different kinds, yes.

What treatment, for instance, have you tried before you tried Dr. Tucker's?—On one occasion I was advised to go to the waters of Mont d'Or in France, said to be very good arsenical waters, and afterwards a course of Nauheim baths here in London, but neither of them did me much good; they were both beneficial to the general health but of no benefit to the special complaint.

Have you consulted many doctors?—Yes, several.

I take it generally you have tried all kinds of remedies?—Practically speaking I should think all recognised remedies, and all under medical advice.

I want to take you back to a year or two ago. Do you remember having an acute attack in London a year or two ago?—It was a year ago last November or December possibly.

I am not sure whether you were on your way from the Continent. Were you in London on a visit?—I had promised to come here to attend the debates on the Education Bill. London is a place which disagrees with me, as a rule, in winter, and I keep away from it as much as I can, but I was obliged practically to be here and I was rather afraid I should have to go on account of this complaint.

You tell us you had a severe attack during that time?—Yes. "Attack" is not perhaps the proper word for it because I was not laid up, but I was constantly suffering.

Breathlessness?—Breathlessness.

Did you consult anyone?—I consulted Dr. Mitchell Bruce of Harley-street.

Was that the first time you had been to see him?—No, off and on I had seen him for a good many years—I daresay 20 years, or more perhaps.

What advice did Dr. Mitchell Bruce give you?—Dr. Mitchell Bruce gave me a tonic to take internally but for the breathlessness he said he could only recommend Mr. Tucker's cure.

Had you heard of Mr. Tucker's cure before?—Yes, I had been advised by a doctor in Paris about two or three years before to try it.

I do not know whether you recollect who that doctor was?—His name was Müller, a French doctor.

Did Dr. Mitchell Bruce tell you where you could get Dr. Tucker's cure?—He told me it could be procured from Mr. Tucker himself; it was not sold by any chemist.

Did you know his address?—No, and Dr. Bruce could not tell me.

How did you find it?—Dr. Bruce advised me to go to various chemists, and he said possibly I might be able to find it, but he could not be sure.

To take it shortly, you did in fact, I think, find it from some chemist?—I found it from Messrs. Savory and Moore.

Did you go to Mr. Tucker's house in Herne Hill the same day that you were successful in obtaining the address?—I took the train at once from Victoria Station and went down to Herne Hill.

Whom did you see at Mr. Tucker's house?—I saw a lady.

I think she showed you the atomiser?—She showed me the atomiser and gave me some explanation of it, and probably allowed me to try it, but that I cannot distinctly remember.

Did you take it on this trial system or did you buy it outright?—I bought it outright.

do not know whether y knew of the trial system?—I knew of the trial system.

Since then what use have you made of the atomiser and this specific?—I have used it constantly, except in very fine, warm weather. In summer I get on, as a rule, without it, but at this time of the year I am never without it, especially when I am in London.

What has been your experience of its effect on your breath troubles?—It remedies them absolutely.

To what extent during the attacks which you have had since you have got it have you used the specific?—Whenever I have been able to. I have always used it.

Whenever you have had an attack?—Whenever I have had an attack.

Have you ever experienced the slightest ill-result from using it?—No, never the slightest.

Has your experience been or not, that the effect wears out with frequent use?—No, quite the reverse. I think that I am distinctly better than I was a year ago. I am not cured and do not pretend to be, but I am distinctly better.

How long does an ounce of specific last? That is 8s. worth, is it not?—I cannot recollect the price exactly.

Never mind the price. Do you recollect about how long one lot of it lasts?—A very long time, but I could not exactly tell you how long. I think I have only once had to buy any more since I first got it. It lasts for a very long time.

So that you are still using the same atomiser and you have had one renewal of the specific?—I think I have had one renewal of the specific. I do not like to be sure because I am on my oath, but I can only recollect one.

So that a year's treatment or over a year's treatment cost you a little over £3?—Yes. I may say I still have a bottle which has not been opened yet.

General Manager, 'Onaway,' Half-Moon Lane, Herne Hill, London, S.E." Whatever else may be said about those terms they are perfectly explicit; there is no sort of possibility of mistake about them. Mr. Tucker says to people who desire to be purchasers of this specific: "Now the price will be so much, if you buy it; you can try it for a fortnight, and if you find it is not useful in your case or it is not what you desired to have, send it back, and there will be an end of the matter"; and he states what the other prices will be. That is the memorandum of the terms of dealing. The person who desires to purchase, or, at any rate, to try the specific, finds in the pamphlet or with the pamphlet a little form to be filled up with his name, address, and the particulars of the symptoms from which he is suffering with a view to seeing roughly whether the man who sends for this apparatus appears from what he says to be really suffering from asthma, because, of course, Mr. Tucker does not want these unusual terms of dealing, this supply of apparatus, and the remedy without payment for a fortnight, to be made the means of imposition. He wants to know a little about the applicant and the application, and so he has a schedule of questions here which the applicant can fill up and will fill up if he desires to have the apparatus on trial, and of course will not fill up if he chooses to send his £3 and knows all about it. Then on the back of the form of questions is this form: "Patient will fill out this blank. Asthma case of," so-and-so; then "Post Office," so-and-so; "box," so-and-so. "Number and street. County or shire. Province or country. Date," this undertaking to be signed by the person who sends in his application to have the specific and the apparatus. "At the expiration of the 2 weeks' trial, I, the undersigned, agree to pay for the treatment or return the Atomizer, and what fluid there may be left by mail charges prepaid." Then there is a space for the signature. That is the ordinary way of carrying on this business which is attacked as a fraudulent concern.

Mr. Justice RIDLEY: I do not quite follow this. The front part of that paper seems to be directed to inquiring whether the remedy has been found efficacious—some of the questions at all events: "Does the remedy generally give you relief?" Does that allude to other remedies?

Mr. DUKE: That refers to question 9: "What remedy are you now using to relieve the attacks? 10. Does the remedy generally give you relief?"

Mr. Justice RIDLEY: He signs this paper before he gets the medicine?

Mr. DUKE: The applicant signs this before he gets the vapouriser and the fluid on trial, and if he chooses to sign this and gives them particulars about himself, which are, at any rate, some kind of guarantee to Mr. Tucker that he is a man who really does want to treat himself with a view to dispelling or preventing attacks of asthma, and to whom the treatment may be of some use, upon receiving this signed, Mr. Tucker sends out the vapouriser and the supply of fluid, and there is a period of a fortnight during which the applicant makes his trials if he wants without incurring any sort of liability, and with the right at the end of the time, whether he does it fairly or not, of packing the thing up in a parcel and putting it into the post with the proper parcel postage upon it and sending it back to Mr. Tucker and saying "Good-bye," or leaving him without saying "Good-bye"—merely returning it. This is the mode of carrying on the plaintiff's business, and the result of the various methods to which I have referred, the distribution of the pamphlet, the employment of agents, and this method of free trial of the remedy in order that the proposing purchaser may know himself upon what terms he is dealing, have undoubtedly been very successful to the plaintiff. Up to the present time since he came to England in 1899 more than 25,000 of these appliances have been supplied. There have been more than 25,000 purchases. Something like half of them have taken place during the last three years, so that you see the mode of doing business which the plaintiff pursues has had this success, that there has been a gradual progress during the earlier part of the time and an increase in the last three years, a very rapid increase indeed, and up to the present time a very large sale. The plaintiff will tell you that, sending out this apparatus and the fluid in the way he does, in about one case in five of the cases where the apparatus and fluid are sent out the applicant returns them and there is an end of that matter. He finds that he is not pleased or that he cannot use it or that for some reason or other he does not consider it is worth his while to buy. He may find that you can buy a spray apparatus or a spray producer at the chemist's very cheap and that you can buy something from which a spray can be produced very cheap, and he may not think, on looking at it, that the thing is worth the money. It is impossible to say what are the reasons why in about one in five of the cases where these applicants come to the plaintiff the applicant does not follow the matter up but in the course of this fortnight of trial sends the thing back and has done with it. In the case of the other four-fifths, what the plaintiff finds by experience is that they go on using the specific, that they give their repeat orders for the fluid, and that they give their repeat orders because things have got worn out in the course of time for the vapouriser, and he will tell you that he has upon his books very considerable numbers of customers who have been customers for many years and who go on keeping the inhaler by them and keeping the specific by them in order, if there are symptoms of the recurrence of asthma, to prevent or cut short the attack. It is a very remarkable circumstance in this case that a very considerable number of the purchasers of this specific who have been purchasers for long periods of time are members of the medical profession. Owing to what has taken place in this case I shall have to bring before you, not very willingly on their part, some members of the medical profession who will tell you for what reason they have been buying this specific for years. One of them is Sir Stephen Mackenzie, the most eminent specialist, I understand, in diseases of the respiratory organs. I do not suggest that Sir Stephen Mackenzie wants to come here to give evidence on behalf of the plaintiff—I must withdraw that, I am told that Sir Stephen Mackenzie is now out of this country. It is sufficient for the present to say that a customer who has been a purchaser of this specific for years is that eminent man, and there are great numbers of other doctors. We have subpœnaed them, and I am told that in the course of this trial we shall put them into the box to hear whether there is any other explanation of their repeated orders for this commodity except that it is an honest remedy in their experience of it. There is a list, I am told, of upwards of 250 medical men in this country and on the Continent who have been buyers of this specific, which is attacked by THE LANCET apparently on behalf of the medical profession because THE LANCET regards it as necessary in the public interests and in the interests of the medical profession. You will have to consider how that may be. It is not limited to that considerable body of medical men; if it becomes necessary to go into the matter my client will take some of the letters of the alphabet in his list of customers and can give you the names of persons of undoubted character and undoubted position who habitually for long periods have been using this remedy.

Mr. Justice RIDLEY: It does not effect a cure so that you can finish with it.

Mr. DUKE: I am told that the only mode in which you can cure asthma is by preventing the attack and that the liability to the attacks of asthma is as constant as the liability to catch cold but that the symptoms when they show themselves can be dispelled by the use of this specific. Gentlemen of the jury, that is the nature of the plaintiff's business and the mode in which it has grown up and the extent to which it has come; and as you will see, if the plaintiff is unjustly attacked the attack is very serious upon him in his material interests, just as it is with regard to his character and reputation. Having mentioned these matters to you I will come to the particular incidents out of which the attack which has been made sprang and the attack itself, and the defence which is sought to be set up here for making the attack and persisting in it. In February, 1904, a man of the name of Cushing sent in to Mr. Tucker a form in which he requested to be supplied on trial with the specific. He described himself as of Queen's Buildings in the Borough, as of the age of 39 years, as being by occupation a fitter, and said he had asthma for seven years, and that it had begun through his having bronchitis, and he went into a good many particulars with which I need not trouble you now. Then on the back of the form he stated his case as the case of Alfred Cushing and gave the address again and did not sign the terms, but although he did not sign the terms the specific was forwarded to him and in due course he became a purchaser, and from time to time between February of 1904 and the latter part of the year 1906 he obtained some additional supplies of the fluid. The plaintiff will tell you to what extent. It is not a thing which rapidly exhausts itself, but it may get

Mr. SMITH: I think you commenced your life by teaching at a public school?—Yes.

Did you, after various other occupations, help your brother in his work in the United States?—I did.

What is your brother's name?—Nathan Tucker.

In what part of the United States does he carry on his profession?—In the State of Ohio.

What assistance were you giving him?—I took the commercial side of the business and was introducing the remedy.

During what years were you attending to the commercial side of the business?—From 1889 to 1899.

Ten years?—Ten years.

During that time were you ever brought into contact with people suffering from asthma in selling these things?—I was travelling from city to city picking out extreme cases and giving them a two weeks' trial free.

So that you were brought constantly in touch with people suffering from asthma?—I was.

I want to ask you a few questions about your brother. Of what age is your brother now?—He is 70.

Where did he study medicine?—At the Bellevue Hospital Medical College, New York City.

Do you recollect how long he was there?—He was there two years.

Where did he go after that?—That was his last medical college.

What was the first one? I want to have the medical course he went through.—He spent two years in Northern New York.

Mr. Justice RIDLEY: What is Northern New York?

Mr. SMITH: Just explain that.—There is the State of New York and the city of New York. Our home was 200 miles north of New York city.

Did he study medicine there?—He studied medicine there.

Mr. ELDON BANKES: At his home?—Under a Dr. Allen for three years.

Mr. SMITH: Is that a common course to adopt in the United States?—It was at that time.

It was some considerable time ago?—It was in 1866 that he finished his course.

He spent three years as you have told us with Dr. Allen in Northern New York and after this he went to the Bellevue Hospital Medical College at New York?—Yes.

You have told us he was there for two years?—Yes.

What was the length of time necessary in order to graduate at Bellevue Hospital?—At that time they allowed a person to graduate with two full years provided he entered at a certain standard which was accomplished by the three years' previous study.

With that qualification two years actual course at the hospital was sufficient to justify graduation if the examination were passed?—Yes.

Did your brother graduate?—He did.

With the degree of Doctor of Medicine?—Yes.

I think that was on the 1st March, 1866?—Yes.

Will you tell us about the college? What is the standing of this college?

Mr. ELDON BANKES: I object to all this.

Mr. DUKE: We will leave it for cross-examination. I do not think it will be suggested that Dr. Tucker is not a reputable man in the United States.

Mr. Justice RIDLEY: We cannot go into the history of the college unless Mr. Bankes wants it.

Mr. SMITH: I think your brother commenced a general practice as a physician in 1866?—He did.

Where did he commence practising?—In Mount Gilead, Ohio.

For how long did he continue to carry on a general local practice?—Up till about 1890, and then this business took his attention and he followed this speciality.

What special line do you mean?—Diseases of the respiratory organs, asthma, bronchitis, and so on.

Do you know how he first came to specialise in these diseases?—It was the result of 20 years' experimenting on himself that he obtained this remedy.

How was he led to commence those experiments?—By the extreme suffering that he underwent.

Do you recollect when he first began to suffer from asthma in a severe form himself?—It was about 1870 that the asthma became very severe. There were slight attacks previously to that.

From 1870 to 1890 did he suffer almost continuously from the disease?—Yes, for months at a time he never could lie down.

Mr. ELDON BANKES: I do not want to interpose as to anything that is relevant, but does this matter?

Mr. DUKE: I think this is material.

Mr. Justice RIDLEY: You can take this generally.

Mr. SMITH: I will take it as shortly as I can.

Mr. Justice RIDLEY: I do not think you have gone too far at present.

Mr. SMITH: During those years from 1870 to 1890 you have told us he was experimenting on himself. I want you to tell my lord and the jury with what result?—He kept getting worse for some years. I think for the first ten years he kept getting worse and then he changed his ideas as to the cause of asthma and commenced treating it directly as a local trouble.

The general view of the profession being——

Mr. ELDON BANKES: We cannot have that from this gentleman.

Mr. SMITH: At any rate, your brother formed the view at that time that it was a local trouble?—He did.

Which did he discover first, the specific or the atomiser?—The specific was discovered before this atomiser was discovered.

Having got this specific what was the object of the atomiser?—He wanted an atomiser which was durable and which would produce a perfect vapour, and that led him to experiment with this atomiser until it was produced.

Why is it important to have a vapour and not moisture?—Because it must be inhaled through the bronchial tubes into the lungs, and if it were not vapour it could not be done.

Mr. ELDON BANKES: You do not suggest a vapour is not moisture?

Mr. DUKE: Of course, in a scientific sense it is a moisture, but it is not a coarse moisture.

Mr. Justice RIDLEY: It is a fog.

Mr. DUKE: I should think that describes it quite accurately.

Mr. SMITH: Do you recollect when it was that he evolved the atomiser in its present form?—It was about 1891 or 1892 that this instrument was produced, but not exactly as it is now. Substantially it was the same.

Have you examined other atomisers which are in use?—Yes.

It is said that one just like yours can be bought at any chemist for a very small price. Have you seen any of these which you have tested in any chemists which resembles yours?—I have not.

If you are asked about it you will be able to point out differences?—I would.

Differences in the product, in the result?—Yes.

What is the distinction between a spraying instrument and your atomiser?—A spray would fill the throat with a quantity of liquid. This instrument of ours converts that liquid into a vapour. I can soon show that better, perhaps, than describe it.

Mr. Justice RIDLEY: I suppose it is turned into minute particles so that you cannot see it, but it must be there.

Mr. ELDON BANKES: You can see it quite clearly if you hold it up to the light.

Mr. SMITH: May the witness do it?

Mr. ELDON BANKES: The pamphlet says that you are not doing it properly unless you see the smoke coming out of your mouth. (to the witness) That is so, is it not?—No, it is not strictly true, but partially true.

Mr. Justice RIDLEY: Is that in the pamphlet?

Mr. DUKE: I think it is in the directions, not in the pamphlet.

Mr. SMITH: (To the witness) What is that spray which you have there?—This is another atomiser.

Is that as good a one as you know, apart from yours?—It is as to the product produced; it is all that you could ask for; but the quantity in volume is almost infinitesimal.

As compared with the other?—As compared with mine.

Mr. ELDON BANKES: Would you mind identifying that. Is that Oppenheimer's?

Mr. SMITH: You call that Oppenheimer's atomiser, do you not?—That is the name by which it is known.

Mr. Justice RIDLEY: Is that going to produce spray?—It produces a vapour, but in very, very small quantity. If I had some of the medicine here I could charge it and show you, but I do not suppose any of you could see it, it would be so fine.

Show us yours.—(The witness illustrated the working of the atomiser.)—I am in a bad position, a dark corner. I do not know whether you can see it very well.

him. It appears to us extremely unlikely that the Coroner would have done so in our client's absence" (a very proper observation, I should think). "Will you be good enough to refer us to the newspaper report upon which your remarks were based? We enclose a pamphlet issued by our client. On page 80 you will find a memorandum of the terms on which the atomizer and specific are supplied to probable purchasers." That is the memorandum which I read to you. "You will see that the atomizer and a sufficient supply of the specific are sent on trial without payment or deposit, the only liability being *to* return them within two weeks if not found satisfactory. Payment is only required if the applicant retains them. The atomizer and specific are both of a very special nature. As to their efficiency we refer you to the pamphlet enclosed. They have been used and recommended by numerous members of the medical profession in the United Kingdom. Our client's business is a large and increasing one. He opened a London office in 1899 and has *since 1902 resided* and carried on business at his present *address. The business* has been honourably conducted throughout. Dr. N. Tucker is a regular graduate of the Bellevue Medical College of New York City, U.S.A., and is legally authorised to practise as a physician in the United States and to use the titles of Doctor and M.D. He has practised as a physician at Mount Gilead, Ohio, for about 27 years. The atomizer and specific are not advertised in the public press. A sense of justice and right feeling should, we think, have led you to communicate with our client before making the offensive and injurious remarks contained in the paragraph complained of. Had you done so you would have received such information as would, we are convinced, have shown that there was not the slightest ground for adverse comment. A grave injury has been done to our client, both in reputation and in property, and we, on his behalf, request you to make what reparation is possible by publishing an ample apology for the injurious statements and a withdrawal of all imputations. We have our client's instructions to commence proceedings for obtaining legal redress if such an *apology* and withdrawal are not published, at latest, in your issue for the 18th inst."; that gave him nine days. "We shall be obliged by your acknowledging the receipt of this letter." Now, gentlemen, if the plaintiff's business is such a business as I have described to you, if his terms of dealing are in truth those terms of dealing which were laid before the defendant in the memorandum, if *this* specific is in any degree an honest preparation, what was the business of the defendant when the defendant got that letter *showing him* in what position he had placed, not only the plaintiff, but him, the defendant himself? His business was, as he knew nothing, apparently, about Mr. Tucker or Dr. Tucker, or the specific, or the mode of dealing which he had reprobated in such unsparing terms, to find out what were the facts and if he was going to continue to attack Dr. Tucker and Mr. Tucker and the specific and the mode of dealing, to *do it* upon knowledge. That is just what he did not do then and what he has never done since. With that knowledge before him *on* May 13th the editor of THE LANCET wrote this letter to the plaintiff's solicitors:—

> DEAR SIRS,—The statements that a labourer who *had* died of consumption had been using an inhaler which cost £3 3s. and a spray at 8s. an ounce were made at an inquest reported in the *Morning Advertiser* on January 2nd, 1907. We should like *to* know which of them you challenge. The documents handed to the City coroner bore the title, "Dr. Tucker's Asthma Specific." The City coroner is reported to have said "It is a quack remedy," and "*It is a fraud*"; we expressed our *view of* this language upon the statements before us.

That is not true. They did not express their view of that language; they say: It is a fraudulent system of dealing; it is rightly stigmatised as a fraudulent system of dealing; and they themselves took the responsibility on themselves of classifying the plaintiff in this action with the rogues who they said plundered and poisoned the public. You will remember the terms of the libel. That is what they have done and they write to us: We should like to know whether a labourer who had *died of* consumption had been using an inhaler which cost £3 3s. and spray at 8s. an ounce. Suppose it were true that a labourer who died of consumption had bought an inhaler for £3 or £3 3s. and had bought a fluid at 8s. an ounce how far would that go to establish a fraud upon anybody? If the labourer had been deceived by Mr. Tucker into buying something then, of course, Mr. Tucker could be stigmatised as having been fraudulent in his dealings. Nothing of the sort. They supposed, apparently, that if it be true that Alfred Cushing, after trial of this specific for a fortnight, bought the apparatus at the price at which he was told he could have it and afterwards bought a new supply of the fluid at the price at which he was told he could have it, that warrants them in declaring that the plaintiff's business is rightly stigmatised as a fraudulent system of dealing and that the plaintiff and the inventor of the remedy itself are to be classed and stigmatised in the way in which it is done in this libel. My clients could not accept that mode of dealing with this matter, and *on the 14th of May they followed* up this. They pointed out, as the newspaper, the *Morning Advertiser*, seems to have led them to point out, *that upon the newspaper* expressions which the defendant produced he was wrong. It was quite immaterial whether he was *right or wrong*, but this further letter was written on the 14th of May: "We have to-day seen the report of the inquest appearing in the *Morning Advertiser* for January 2nd, 1907. Replying to your letter, the statement made at the inquest respecting the price of the inhaler and spray was misleading by reason of the omission of any reference to the terms on which the articles were supplied to purchasers. The coroner's remark: 'It is a quack remedy,' is not in accordance with fact. It *seems* clear to us, from the report, that the coroner's final remark, 'But it is a fraud,' did not relate to the inhaler and spray. We *mentioned in our previous* letter that our client had no opportunity of being *present* at the *inquest.*" At some time or other those newspaper *paragraphs* will be read to you; but apparently the coroner had said that it was very wrong on the part of the public authority in this country to allow specific remedies which were not prescribed by doctors, but which could be bought at a shop, to be sent out under a Government stamp, and that that was a fraud, that it led people to suppose that the Government vouched the value of the remedy. Something of that kind the coroner appears to have said, but we shall hear. On the 21st of May, having got those two answers, instead of an honest attempt either to be in a position to justify these charges or a withdrawal of them the plaintiff's solicitors wrote and *said*: "*Referring to* our correspondence with the editors, we are instructed by Mr. A. Q. Tucker to commence proceedings against you in respect of defamatory statements contained in your issue of 9th March last, page 701, and shall issue the writ to-morrow. Please send us the name of solicitors who will accept service of the writ on your behalf," and then this action was begun. Now, I will tell *you shortly* what the defendant has done in this action with a view *either to* mitigate or to aggravate the injustice which upon the *facts* which I have stated to you, I venture to say it is perfectly clear he has done Mr. Tucker. He came to deliver his defence *on July 9th*, last year, and what he said in his defence—the substantial part of it, and the only part which is material to the observations I have to address to you—was: "The said words are fair *comments made bonâ fide* without malice and in the honest belief that they were true on certain matters of public interest—viz., (*a*) an inquest held by Dr. F. J. Waldo, the City Coroner at Southwark, on Jan. 1st, 1907, *on the* body of a labourer named Alfred Albert Cushing *and the* statements and evidence given at the said inquest and in particular the evidence of Dr. G. A. Paton that the death of the said Alfred Albert Cushing resulted from old-standing and advanced consumption and the evidence of the deceased's widow that the deceased used according to printed instructions produced before the said coroner an inhaler known as Dr. Tucker's atomizer which *cost* three guineas and a spray known as Dr. Tucker's *Asthma* Specific which cost 8s. an ounce and the following statement of the coroner: 'Tucker's Asthma Specific appears to be an American thing ...... Gentlemen, this is what I call a quack remedy. I have had a number of cases of quack medicines in connexion with which credulous people are deceived by seeing *the* Government proprietary article stamp on them and are deluded into believing that the Government guarantee the contents. They get a very rich harvest out of the sale of the stamps'—*that is obviously* the Government—'but the sooner they do away with *the stamps* the better, so that the public may be undeceived ...... anyway, gentlemen, the remedy [meaning Tucker's asthma specific] is a fraud.' (*b*) The sale to the public at the price of 3 guineas of Dr. Tucker's atomizer and at the price of 8s. an ounce of his asthma specific. The constituents of the said specific are cocaine and *atropine* (which are poisons and dangerous if used without medical advice), sodium nitrite, glycerine, oil of gaultheria, and water. Quantities of these constituents sufficient to make up one ounce of the said

And some of the parts of the atomiser also come from the States?—Yes.

And it is completed with the other parts from the continent; I think that is clear?—Yes.

How many shipments a month do you say you have?—About four.

Can you tell us what the average payment for carriage would be on one monthly shipment?—I get 100 of these packed in a box like this at each shipment and about 32 quarts of medicine. For those two lots I pay from £1 to £1 4*s.* or £1 5*s.* It varies somewhat but it is somewhere about £1 3*s.* I would say as the cost for each shipment. That is the cost from New York State; that is the ocean freight.

How about the State charges on the other side?—It is a little more from Ohio to New York State than it is across the ocean. It is 800 miles by rail.

So far as regards the parts of the atomiser which are obtained from the continent, do you pay for the carriage of those indiarubber balls and glass bottles?—Yes; I pay for all that.

How often do you have a consignment containing the indiarubber balls and the glass bottles?—You understand that the rubber balls are made here in London.

But the glass bottles in France?—The glass bottles in France.

How often do you get a consignment of glass bottles?—About once in four months.

Is that a large case or not?—Yes; it runs I think about 25 gross.

Do you remember roughly what the cost of carriage of that would be?—No; I do not know. It is not a very great amount; I think some five or six shillings or something like that.

How long did you stay in the office at Holborn Viaduct, which was the first one you took when you came over to this country?—I stayed there nearly three years; I left there in June, 1902.

Are you sure it was 1902? You may be right but I have it 1903.—It was 1902, June.

Where did you go after you left Holborn Viaduct?—I went to Herne Hill.

Have you been there ever since?—Yes.

I think you use the house as a residence and to carry on the business?—Yes.

Mr. Justice RIDLEY: You do not want any dispensary; all you want to do is to decant the liquor into the bottles?—That is all. It is a distributing centre.

Mr. SMITH: When your lordship sees the volume of business your lordship sees there must be conveniences for distributing.

Mr. Justice RIDLEY: When I look at this picture there seems to be no convenience there; it is a villa. I have a picture of it.

The WITNESS: That is my dwelling-house and four rooms devoted to business on the ground floor.

It looks as if it were devoted to enjoyment.—Well, it does.

There is no notice—a board or anything.

Mr. SMITH: You do not advertise, I think, either on your door or anywhere else, do you?—My name is on the gate-post so that strangers may know when they reach the house.

But that is the only advertisement you have apart from this pamphlet?—Yes; I do not put anything outside except merely my name, A. Q. Tucker.

While I am upon that I will just ask you the question, Do you advertise at all in the newspapers?—I do not.

I want to ask you about the gross yearly receipts since the time when you started your business. I think you have a book here, have you not?—Yes.

Mr. Justice RIDLEY: You do not have anything up on the blind or anything of that kind; you do not have any notice up at all; it is simply a private house?—That is all.

Mr. SMITH: Simply "A. Q. Tucker"?—"A. Q. Tucker" is on the gate-post.

While I am getting the gross receipts can you tell my lord and jury how many of these atomisers you have sold since you commenced business?—We have sold upwards of 25,000 and the names are entered on our books as patrons.

Mr. Justice RIDLEY: All fresh patrons?—Patrons that I have gathered up in the seven years since I commenced here.

But some people wear out an atomiser and have to buy another?—Yes; a great many of them have two.

Mr. SMITH: So that they would not all represent different customers?—Yes; but I have that many different patrons—over 25,000.

You have the books so that my friend can see them if he wishes to?—The books are here and they can be seen.

You have 25,000 different patrons?—Yes.

Which you say would represent a much larger number of atomisers sold?—Yes, much larger. Many business men have one at their house and one at their place of business.

Mr. ELDON BANKES: You might give us the summary of the receipts.

Mr. SMITH: My learned friend allows me to give your lordship a summary.

Mr. ELDON BANKES: We have had inspection of the books. They disclose them in their affidavit. If the summary agrees with mine I have no objection to putting it in.

Mr. SMITH: I will give your lordship the figures for the year 1899.

Mr. ELDON BANKES: Are those the gross receipts?

Mr. SMITH: Yes, the gross receipts. He began business in August, 1899, and up to Dec. 31st in the first year of business the figures were £402 18*s.*, gross receipts; in 1900, £3672 7*s.* 5*d.*; in 1901, £8785 11*s.* 10*d.*; in 1902, £11,070 2*s.* 11*d.*; in 1903, £14,982 2*s.* 1*d.*; in 1904, £17,251 0*s.* 11*d.*; in 1905, £19,585 14*s.* 8*d.*; in 1906, £19,641 8*s.* 5*d.*

I do not think you have been able to take out the last month or so of 1907 and your figures so far as they are taken out——

Mr. ELDON BANKES: To what date?

Mr. SMITH: You shall have it. As far as the figures are taken out—and I will give my friend the exact date in a moment—the figures for 1907 are £18,498 17*s.* 10*d.* I do not know whether you can tell me the date or whether I must get it from the book.—No, I cannot.

It has been done by an accountant, and you do not know. I want you to help me as far as you can in discovering the cost price to you of the atomiser and the specific and the accessories. I think you have one of Dr. Tucker's weekly statements of account, have you not?—There is a book there which you had which contains the weekly report of every week since we started.

I want you to take any week at random, but I just want my lord and the jury to see how the statement of account, as between your brother and yourself, is made up.—I am fearful that the book is not here.

Mr. ELDON BANKES: I must object to it going in without the book for the moment. I am not certain I have seen this. What is it you want?

Mr. SMITH: I want his estimate of the cost price to him as arrived at by the account with Dr. Tucker. I do not care about it, and I will leave it to my friend to ask about.

Mr. Justice RIDLEY: I do not know whether we shall want that. I have appreciated that there are some questions in the libel which point to the price being material.

Mr. ELDON BANKES: Yes, it is material to get the figures.

Mr. Justice RIDLEY: I think so, but I was not quite sure how far it was material.

Mr. SMITH: If it is still persisted in and relied on as part of the defence——

Mr. Justice RIDLEY: One sees at once that the £3 charged is not charged on the face of it as anything like the price of it; it is a charge for the cure as well.

Mr. SMITH: Yes.

Mr. Justice RIDLEY: To give it to a man for a fortnight and then ask him to pay £3 means the cure as well as the article.

Mr. SMITH: Quite.

Mr. Justice RIDLEY: However, you may go into it if you like; the jury will deal with all that. (To the jury) I tell you, gentlemen, that £3 is out of all question, not the price of one of these atomisers; it is not anything like it. £3 must be far beyond the proper value of any one of these things.

Mr. SMITH: Yes, of course. There is no concealment about that, obviously.

Mr. Justice RIDLEY: It is intended to be the price of the cure I should have thought, but we shall see what Mr. Bankes says. The man agrees to pay in a fortnight and if he does not choose to pay he sends it back again and does not pay; if it is of any use he does.

Mr. SMITH: Some case apparently still is made about the cost of the thing and I think I should just like to ask him deal with any charges which they thought fit to make upon their own responsibility, and they have sheltered themselves behind what they say was the opinion of the coroner, whereas what they have charged is not a matter of opinion but a matter of fact—namely, a fraudulent course of dealing and a fraudulent system of business. That is the outline stated at greater length than I intended to have taken up in dealing with this case. The grievance which the plaintiff complains of is the grievance of the charge of fraud which I have mentioned before. With the assistance of my learned friend I shall call a considerable body of evidence before you to show what the plaintiff's mode of doing his business has been, and the value, in any sense in which you can speak of value, to the persons who have applied his remedy has been, and when you have heard that evidence and heard any further excuses which the defendant may find to be available to him it will be your business to say what amends ought to be made to the plaintiff in respect of this charge of carrying on a fraudulent business, made in the first instance, I am willing to believe, in ignorance of what the plaintiff's method of business really was, but in substance persisted in under various cloaks and covers down to the present time. My learned friend and I will call this evidence before you and you will hear what the defendant has to say. My lord, there are a couple of witnesses whom I should like, if I may, to interpose before the plaintiff because I cannot keep them. One of them is the Earl of Harewood and the other is a member of the Bar.

Mr. Justice RIDLEY: Very well.

Mr. ALEXANDER DINGWALL BATESON, *examined by* Mr. SMITH.—You are a member of the Bar?—I am.

I think from childhood you have been liable to asthmatic attacks?—Until I bought Mr. Tucker's specific.

At what age as far as you can recollect did your constitutional tendency to these attacks develop *itself*?—To my certain knowledge at eight years of age.

And from that age how long was it until you heard of Dr. Tucker's remedy?—I think it is about four or five years ago, but I am not quite sure of the actual date.

Mr. Justice RIDLEY: That was the first time when you bought that remedy?—The first time.

About four or five years ago?—I think it is about four or five years ago, but Mr. Tucker will be able to tell exactly from his books.

Mr. SMITH: I do not know whether you would mind telling us how old you are now?—Rising 42.

So that for about 30 or 35 years you were suffering from asthma and you did not know of Dr. Tucker's remedy?—That is so.

Will you tell my lord and the jury what degree of trouble you had from asthma before you heard of Dr. Tucker's specific?—As I grew older it was getting worse, and constantly for weeks together I could hardly sleep at all. I could do my work during the day but at night it was very troublesome. After I bought this specific I have been able to sleep perfectly well and I have never had any trouble from the asthma at all.

So it was proving a real difficulty in your way before?—It was getting more and more troublesome and I thought really getting serious.

Before you came across Dr. Tucker's remedy did you consult any doctors?—Well, my earliest recollections are being under Sir William Jenner, and as a child I used to go and see him from time to time nearly up to the time of his death, I think. Since then I have not bothered very much with doctors at all.

Even with his advice did you get the relief which you have had since you have used Tucker's remedy?—No, I had recurring attacks in the same way. I daresay there was a certain amount of relief from time to time, but I never was free from severe attacks.

Has the use of Dr. Tucker's specific involved a growing use?—Oh, no; the longer I use it the less I use it, if one may say so; the longer I have had it, the less I find I have had to use it.

You get relief more easily?—I really hardly require it at all.

Something has been said about the price of this specific. What price do you pay for one instalment, so to speak, of this specific?—I pay about 8*s*. every 12 or 18 months.

Is the amount which is sent to you adequate for that period?—It is the ounce quantity; I get the ounce quantity and I pay my 8*s*.

And in your experience you find that lasts you 12 or 18 months?—I think so; certainly 12 months, and I think more.

Will you tell my lord and the jury how you came to give evidence in this case?—I saw some proceedings in the Court of Appeal with regard, as I thought, to an attempt to discover what the secret was, and, seeing that the case had reference to this remedy, I told you that I could give evidence as to how satisfactory the remedy was.

You volunteered it?—Certainly, absolutely.

Cross-examined by Mr. ELDON BANKES: There is nothing on the bottles which you have purchased to indicate what this stuff contains?—No.

Have you been using it without knowing that it contains two poisons, cocaine and atropine?—I have been told by various doctors that it contains poisons, but all the doctors have fed me on poisons ever since I started.

We will see in a moment; but it is common knowledge, is it not, in the medical profession that this Tucker's specific does contain poisons?—Well, they say so, but I do not think they know.

We will see. At any rate, this has been put into your hands without any warning that it contains either cocaine or atropine?—I would not like to say that. I am not at all sure that somebody had not suggested that it contained cocaine.

I mean so far as Mr. Tucker is concerned?—I never asked him.

And there is nothing on the bottles to indicate that it should be used with caution?—None at all; there is nothing on the bottles at all as far as I remember.

So far as you are concerned it so happens that you have used it with caution and you have used it very infrequently?—Not at all; I have not used it with any caution and I have used it whenever I wanted it.

Mercifully for you, you have not required to use it very often?—I did when I first started.

How often did you use it then?—Constantly, especially at night.

I suppose yours is a case of true asthma, is it not? Have the doctors ever told you that?—The doctors have never been able to tell me what it is.

Is your heart sound so far as you know?—I have been passed as a first-class life by the insurance office year after year quite recently.

Do you know the danger of using cocaine if your heart is unsound?—I have used cocaine. I used cocaine to a large extent at one time under doctor's orders for hay fever.

Of course under a doctor's advice and under a doctor's supervision?—Not supervision.

Under his advice?—Under his advice; and it is very nasty stuff.

This stuff tastes sweet, does it not?—There is no trace of cocaine in this that I could detect, although I have taken plenty of it.

So far as it has a taste it is a sweet taste, is not it?—I should say none.

Mr. Justice RIDLEY: Cocaine is the stuff that is used for taking away pain in a tooth, is it not?

Mr. ELDON BANKES: They used to use it until they found the danger of it.

Mr. Justice RIDLEY: I think they use it for that.

Mr. ELDON BANKES: They used to, but they have found it dangerous.

The WITNESS: I think I had some the other day from a dentist.

Mr. ELDON BANKES: I think I can show that it is one of the most dangerous poisons which you could possibly put into anyone's hands.

Mr. Justice RIDLEY: There has been a development about this lately. There is a sort of remedy known as Fellows's syrup of hypophosphites; that contains poisons and I discovered the other day that they have found it necessary to mark it as poisonous and you have to sign the book for it, but it certainly was not done two or three years ago. It is a perfectly well-known article and has been on the market for years and years.

Mr. ELDON BANKES: There is no doubt that there is no right to sell this. It comes under the Pharmacy Act and this is largely sold absolutely contrary to the Act of Parliament.

Mr. Justice RIDLEY: When the poisons have been in small quantities I think it will be found it is a fact that they have disregarded the Pharmacy Act.

Mr. ELDON BANKES: I will not anticipate.

commercial value. It will take some little time to explain just why he does by me as he does.

Mr. ELDON BANKES: Well, I object to that.

Mr. Justice RIDLEY: It has great commercial value; that is all right.

Mr. SMITH: Apart from this staff which you have explained to us do you employ agents?—I do.

You have told us you do not advertise at all. Do you rely upon your agents and customers to make your specific known?—It is principally made known by my patrons who tell one another. My agents are simply local agents who take orders and send them to me to fill.

How many agents have you got?—I do not know.

Roughly, I mean?—Some 40 or 50; it may be twice that; I am not sure. Many of them do but very little, but whatever they do they get their commission on.

I am going to ask you about that. What commission do you pay to your agents in case they effect sales?—I pay a commission of 12*s*. on each complete sale of £3, but that is to those who take up their time and make a business of it. Then we give a commission of 10 per cent., 6*s*., to dealers who simply pass it on.

What proportion, roughly, of your treatments, as I think you call it, are sold or supplied through agents?—Our foreign trade is very largely done by foreign agents, nearly all of it. Here at home in the British Kingdom I do not know; it would be a guess—not over, perhaps, one-fifth.

I think you have agents in most of the chief continental countries?—Yes.

I understand you to say that you do not always pay 12*s*.?—No.

What is the alternative rate?—12*s*. is to the one who goes out and hunts up customers and spends his time and strength. The other is to chemists and dealers who simply order and pass it on and do nothing in the way of explaining to patients.

It is the distinction between the chemist's shop and the one who canvasses for customers?—Yes, not only chemists—shippers.

Have you to make allowance for discount on the fluid for wastage in decanting, and so forth, and accidents?—We do. We guarantee safe delivery of all the fluid we send through the post. If it is broken we replace it free of charge.

I do not want to go into precise figures on this point. You have to make some deduction under that head? You find in your experience that there is a wastage under that head?—Yes.

And, in the same way, when you ship the fluid into this country from the States you stand, I think, the risk of wastage there?—We occasionally get a quart bottle broken.

That is your loss?—That is my loss entirely.

How long ought an ounce of fluid to last if used regularly? You heard what Mr. Bateson said, that his lasted a year. I want to ask you, what is your experience?—The average length of time for one ounce would be three months' daily use.

From the time that you first commenced business in this country have you adopted the fortnight's trial method?—Yes, invariably.

From the very start?—Yes; every person in the British Kingdom has had the privilege of a two weeks' trial.

Before they are allowed to have this trial I think you ask them the questions which my friend Mr. Duke referred to; they have to fill in the question form?—Usually they do; not always.

But you usually send it on an application for a free trial?—Yes.

After they have had a fortnight's trial, of the people who wish to have it, what proportion do you find come to you and buy them?—That is here in the British Kingdom?

Yes, of those who have tried them?—I should think at least four-fifths, but of those who return it the majority get it afterwards.

You have noticed, by following their names in your books, that they do?—Yes.

I do not know—you shall tell me whether you have a system of experimental use in the continental business?—I do not.

It is only for England?—Nor in the colonies; it is confined to the British Kingdom.

As far as any question of fluid is concerned have you at any time, if a customer did not like it during his fortnight's trial, refused to have it back?—Never.

In dealing with expenditure, there is one small item I want to get, and that is about the Government stamp. You have to pay for the Government stamp?—Yes.

What is the price of that?—It is 1*s*. on every ounce.

Of course, there is a deduction to be made for that. I want to ask, as a further deduction, about your income-tax returns.

Mr. ELDON BANKES: I object to that; you cannot deduct your income-tax.

Mr. SMITH: I quite agree you cannot, but if it is relied on that this gentleman is charging an excessive price I should think it was useful to discover what exactly his expenditure was before he could get this. It is on the same footing as his house rent. It may be my friends are not going to rely on this, but if it is I should have thought I could get that.

Mr. Justice RIDLEY: I really do not think you can.

Mr. ELDON BANKES: You cannot arrive at profit in that way.

Mr. SMITH: In all cases in which these questions have been filled up and an application made for a free use do you always send it or do you read the answers to the questions?—I usually look them over to see that the patient has asthma and not heart trouble—not a diseased heart.

In the latter case you would not be able to help him?—We always say to them it would do them no harm but no permanent good.

Do you charge the same price both to rich and poor in selling these atomisers?—We publish but one price, but in cases of charity, where the money is made up by friends, we reduce it one-third—£2 instead of £3.

Have you done that in a large number of cases?—A good many.

Have you made a reduction on a second atomiser in similar cases too?—Yes, we have a standing rule that the second atomiser, stocked ready for use as you see it here, is 16*s*. That is only to our old patrons for their own private use.

I want to ask you about the specific itself. Does anyone prepare the specific except your brother at Mount Gilead?—No one else.

Have you ever prepared any of it or are you capable of preparing it?—No, never attempted it.

You were asked a question which was afterwards disallowed. In fact, do you know to-day what the constituents of the specific are?—I absolutely do not know.

Have you ever held yourself out as possessing medical skill yourself?—Not in the slightest; no.

In your experience have attempts been made to determine the constituents by analysis?—There have.

Mr. ELDON BANKES: To his personal knowledge?

Mr. SMITH: Do you know of this yourself?—I have been told by different ones that they have attempted it.

Mr. ELDON BANKES: Then I object to it.

Mr. SMITH (to the witness): Did you ever send it to anyone yourself for analysis or not?—I never did.

With regard to the suggestion of poison and so forth, is the specific used commonly by young children and young persons generally?—It is used by all ages from three years and upwards.

Do you come across asthmatic cases as young as that frequently?—I have met them as young as three years. I have been told by those who have it that they have had it since four months of age.

At any rate, you have not supplied it to persons under three years of age. Have you ever known of a case in which it has done any injury to any such persons?—Never.

Has a complaint ever been made to you of all the 25,000 customers you have had of any injury done to one of them by the use of this specific?—No; we have had a great many questions asked of us whether it did do certain things.

But I am asking about complaints of injury?—No, never a complaint of injury.

As far as this question of cure goes, what is it that you tell my lord and the jury that this specific in your opinion can do?—It affords perfect relief and it arrests the paroxysm at once.

Do you say that it cures or destroys the liability to asthma?—Never; I do not claim that at all.

Some persons are more disposed to asthma than others?—Certainly.

When you call it a cure what is it you say that it cures?—It cures the spasms.

Mr. ELDON BANKES: He did not say anything.

Mr. SMITH: He calls it in his pamphlet a cure.

Mr. ELDON BANKES: The witness's last answer was quite

So that a year's treatment which you say has been beneficial has cost you a little more than £3?—A little more than £3.

How does that compare with what you were paying to doctors for this same ailment before?

Mr. ELDON BANKES: I object to that.

Mr. Justice RIDLEY: I do not think you need ask that.

Mr. SMITH: Very good. At any rate, have you regretted the £3 that you have spent on this?

Mr. ELDON BANKES: I object.

Mr. SMITH: Surely I am entitled to ask that. He says that he spent £3 on this atomiser. He has given us his experience of the use of it, and I ask him whether he regrets the £3 that he spent on it. It is not worth while persisting in if my friend objects.

Mr. Justice RIDLEY: You need not ask that question either, I should think, because if he has got relief from asthma he certainly does not regret it.

Mr. SMITH: Perhaps so, my lord.

Cross-examined by Mr. ELDON BANKES.—Can you give me an idea how often you use this when you are troubled with these attacks? Is it once a day, or once a week, or once a fortnight?—It would be whenever I have an attack.

Does that often come—every day?—Sometimes perhaps six or seven times a day.

Would you use the atomiser on that occasion six or seven times in the day?—Yes.

Then perhaps you would not use it again for a fortnight?—I should think myself very lucky if that was to happen to me in winter.

But it might be you would not use it again for a week?—I should think myself very lucky again if that happened to me when I was in London.

London is a place which does not suit you?—London is not a favourable place for me. I came up yesterday afternoon and I should think I have used it perhaps three times.

But when you are in the country you can go on for a long time?—Yes, when I am in the country.

Sometimes a fortnight and sometimes even more?—Yes, in the summer. I would rather put it in this way, that I do not use it except when I want it.

I only want to let the jury know how often you do want it, taking one week with another?—Pretty constantly. I would rather put it in that way, if I may be allowed.

I understand it was Dr. Mitchell Bruce who mentioned it to you. Did he indicate to you that he knew anything about it, or did he merely say: "You had better try Tucker"?—He more than implied that he knew all about it. He did not pretend to know its composition, but when Dr. Mitchell Bruce orders a thing I think he implies that he knows something of it.

He did not know where it could be obtained, I understand?—No.

You went down to Herne Hill and there you saw a lady?—Yes.

Did she ask you at all what was the matter with you, or was she merely a vendor? Did she ask you whether you had got any complaint for which it was suitable, or did you merely ask for it and was it supplied?—I think I entered into some detail. I do not know whether she asked me or whether I volunteered it, but I certainly gave it.

And she supplied the atomiser?—She supplied the atomiser and a certain quantity of the specific.

Was any information given to you that it contained any cocaine?—No.

Or atropine?—Or atropine.

Was there no indication upon any of the bottles or boxes that were given to you that it contained poisons?—No.

Mr. Justice RIDLEY: I do not think you told us how long you have suffered.—I do not know exactly how long, but I should say more or less five or six years.

That was the period of time?—Before I knew of Dr. Tucker's remedy.

HENRY ULICK LASCELLES, EARL OF HAREWOOD, *examined by* Mr. SMITH.—Have you been liable for some time to asthmatic or quasi-asthmatic trouble?—Not quasi—asthmatic trouble, yes.

About how long have you had trouble of that kind?—I have suffered more or less for the last six or seven years I should think certainly, but not lately.

During the earlier part of this six or seven years did you take advice as to your ailment?—Yes, I tried every sort of thing. It was entirely the result of influenza with me—repeated attacks of influenza.

Did you take medical advice as well?—Yes.

Did you get relief?—No, not much, not from doctors.

How long is it since you first heard of Dr. Tucker's specific?—I do not exactly remember, but I think about six or seven years ago.

Do you happen to recollect how you came to hear of it first?—Yes, perfectly. I think it was recommended to me by a lady whom I happened to sit next to at dinner and who told me it had done her husband a great deal of good.

It was recommended to you privately by a lady and did you then try it?—Yes, I tried it at once. I sent for it.

What effect has it had on your trouble?—The effect that it has on my asthma is that if I inhale Dr. Tucker's remedy for five minutes, say, at night, in about half an hour my breathing becomes quite clear and I can go to sleep.

Have you found the relief consistent?—Yes, consistent.

And in those five or six years that you have been using it have you experienced the slightest ill-effect from it?—Not the slightest.

Mr. Justice RIDLEY: I think you said you had suffered six or seven years from it, but not lately?—Not lately, or only very slightly for the last year or year and a half.

Is that since you have got this remedy?—I cannot say whether it is this remedy. I attribute it to my not having had a cold for a year and a half. It is the cold that brings it on.

Mr. SMITH: A cold brings on an attack of this quasi-asthma?—Yes, or influenza.

Whenever you have had these attacks you have found relief in the manner which you have described?—Yes.

Mr. Justice RIDLEY: It is as long as five or six years ago that you got the remedy?—I think so; I cannot fix the exact date without referring to accounts, but I think it was about that time ago.

Mr. SMITH: If you had any trouble at all at the present time you would use it?—Certainly.

Cross-examined by Mr. ELDON BANKES.—Did you obtain it through the post?—Yes, through the post.

Did you answer the questions which we know are sent out to persons?—Yes, as far as I remember I did the first time I sent for it.

Did you understand that those were questions which were submitted by somebody in order to ascertain whether the specific was suitable for your case?—Yes, that is what I understood.

Then you bought it and it has given you relief?—Yes.

Was there anything upon the bottle or any of the boxes to indicate that it contained poisons?—No, I have not an idea what it contains.

You had no idea, for instance, that it contained cocaine?—No, I have since been informed that it does.

I mean at the time you were using it?—No.

I understand that these attacks which you have had have been the result of cold?—Cold or influenza, generally influenza.

Have you used the specific constantly or only occasionally when the attack came on?—Occasionally.

Re-examined by Mr. DUKE.—The mode of using this thing is to convert the fluid into a vapour, I think?—Yes.

During the five or six years that you have used the vapour produced in the inhaler have you ever found any sort of ill effect from it?—No, none.

Nothing of the nature of the action of poison?—No, none.

AUGUSTUS QUACKENBUSH TUCKER, *examined by* Mr. SMITH.—Where do you carry on business?—At Herne Hill.

I think your wife and daughter live with you?—My daughter is the only assistant I have.

How old are you?—68.

Where were you born?—In the State of New York.

Mr. Justice RIDLEY: Does that matter much?

Mr. SMITH: I want to ask him a few questions about his early career, which I should think your lordship will think does matter.

Mr. Justice RIDLEY: The particular place of his birth does not affect his career.

Mr. SMITH: No, but the fact that he was born in the States I think does.

Mr. Justice RIDLEY (to the witness): You are a native of the United States?—Yes.

Mr. ELDON BANKES: That is another matter.

Mr. DUKE (to the witness): Look at the date of the letter, that is all. (Document handed to the witness.)—Yes, I remember that coming in and being filed.

What is the period?—The date is given here, Oct. 15th, 1907.

Mr. SMITH: Looking at that letter of 1907, can you say that you got an order?

Mr. ELDON BANKES: I object to that being put in; it cannot be put in.

Mr. DUKE: We do not want to put it in.

Mr. Justice RIDLEY: You say he is one of your oldest patients—that is, as far as I have got at present.

Mr. DUKE: What we proposed to do was to say on the witness refreshing his memory by a document that that custom had continued down to as lately as October, 1907.

Mr. ELDON BANKES: I do not object to that.

Mr. Justice RIDLEY: I quite follow now. He has said so. "He is one of our oldest patients," that means that he is still.

Mr. DUKE: Yes.

Mr. SMITH: You can verify that by your books if my friend asks you about it?—Yes.

Have you got a book with the entries there in front of you?—This is the entry here. This is volume 2. The entry is made here July 16th, 1901.

Mr. Justice RIDLEY: You are not entitled to read the books, of course.—That was the time the treatment was first ordered.

Mr. Justice RIDLEY: All you can do is you can say you have the books here.

Mr. SMITH: Yes, that is all.

Apart from your medical patrons or customers, who you have told us amount to about 300, I want to ask you about your ordinary customers and their position. You have told us of their numbers. Have you supplied this atomiser to persons in all ranks of life, including the highest?—I think our books show every title in the British Kingdom excepting the King and Queen and the Primate, but I think they show every other.

Mr. Justice RIDLEY: Perhaps they did not want any. Have you got the Archbishop of York?—I cannot remember whether we have or not; we have a good many archbishops.

Mr. Justice RIDLEY: The Primate means the Archbishop of Canterbury.

Mr. SMITH: If you are asked about this, you say you can show customers from every rank in English society, even the highest, excepting the King and Queen?—Yes.

I think you have supplied it to many other Royal Families—not English ones but others?—Yes, we have—I think the Royal Family of Belgium.

And even to the families of distinguished English judges?—Yes.

Mr. DUKE: Not, I think, to your lordship's family, as far as we know.

Mr. Justice RIDLEY: I have had none myself.

Mr. SMITH: My learned friend can have the names if he wants them.

Mr. ELDON BANKES: It is new to me that you will supply the names of customers for such a drug as this.

Mr. DUKE: I do not think my friend understood. My friend Mr. Smith said if Mr. Bankes wants this and challenges the names we will supply them; we do not propose to publish them.

Mr. Justice RIDLEY: We are going into the case in a great deal more detail than is necessary in chief.

Mr. DUKE: My learned friend will not take any point that is not necessary.

Mr. SMITH: Indeed, I will not.

Mr. Justice RIDLEY: I should have thought to take it generally on your side would be sufficient until Mr. Bankes challenged it.

Mr. SMITH: I am obliged to your lordship.

Mr. Justice RIDLEY: We must get on at last, I suppose.

Cross-examined by Mr. ELDON BANKES: Do I understand it is the fact that you have never had any medical training at all?—None at all.

And do I understand you to tell the jury that you are selling these enormous quantities of this liquid indiscriminately without knowing what it contains?—That is what I said.

Selling it practically to anybody who asks for it?—No, we do not.

Well, we will see in a moment. Do you take any precautions as to the persons to whom you shall supply it?—We supply it to everyone whom we think it would benefit, and if we think it would not we do not supply them; we tell them it is just throwing away their money.

You supply the people whom you think it will benefit and you do not supply those whom you think it will not benefit; is that so?—That is my position, yes.

What classes of persons do you think that it will not benefit?—A person who has consumption would not get any practical benefit; they may get a little relief but we do not advertise it for that.

Who else?—It is designed for just these cases only.

Would you mind answering my question? I am asking you to tell us the persons whom you think it would not benefit.—It would not benefit any person unless they have a serious catarrhal trouble.

But are there any particular classes of persons whom you know it would not benefit? You mention, for instance, persons suffering from consumption. In your opinion, does this stuff of yours not benefit them?—It does not.

Let me take the case of a person suffering from a weak heart.—They would get benefit only in this way: their breathing is relieved; it relieves the heart—no more.

Do you say that you formed the opinion that this stuff of yours does not benefit consumptive patients without knowing what is in it?—I do not think it would.

Listen! You do not follow my question. You formed the opinion that this stuff of yours would not benefit consumptive patients. I ask you: Have you formed that opinion without knowing what your stuff contains?—I have.

Have you ever had occasion to consider the English Pharmacy Act?—No.

Do you know that there are very stringent provisions with reference to the sale of poisons in England?—I do; I suppose there are as a matter of course; there are in all countries.

Is there any reason that you can suggest to the jury why you have abstained from asking what is in this stuff of yours unless it be that you are aware of the provisions of the English Acts about poisons?—I dispensed this remedy in the States for ten years before I came here.

We will come to the States in a moment. You were on terms of intimacy with your brother?—Yes.

You were in close conjunction with him in this business?—Yes.

Do you say you never asked him what was in this liquid?—I never did.

Do you know now that if you complied with the English law you would not be able to sell this stuff?—I do not know any such thing.

Very well, we will see. Do I understand you to say you do not know now that it contains cocaine?—I do not, not of my own knowledge.

Has anybody in the course of this case, while you have been preparing for trial, sought to ascertain whether it contains cocaine or not?—I presume many of them have.

But on your side?—I do not know what they have done.

Do you know anything of the properties of cocaine?—I suppose it to be a very powerful drug.

Do you know that it is a drug to the effects of which many persons are strongly susceptible; do you know that about it?—I do not know anything about it, for I am not a medical man.

Have you ever heard of the cocaine habit?—I have.

Do you know that that is one of the most insidious habits that anybody can acquire?—I do.

Worse than the alcoholic habit or worse than the morphine habit?—I am not prepared to judge as between that and morphine; I know both of them are serious.

Mr. Justice RIDLEY: That means you cannot avoid taking it?

Mr. ELDON BANKES: You cannot avoid taking it.

Do you know this: a cocaine habit or a morphia habit would be acquired by absorbing quantities of cocaine or morphia into your system?—It certainly would.

Have you sufficient medical knowledge to know that either of those drugs is absorbed more readily into the blood if inhaled than when swallowed?—I think quite the reverse, but I am not a judge.

Are you prepared to dispute that every ounce of this stuff of yours contains a considerable quantity of cocaine?—I know nothing about it.

Are you prepared to dispute, also, that it contains a considerable quantity of atropine?—I know nothing about it.

Mr. Justice Ridley: Can you see it, gentlemen?—The Jury: Yes.

The Witness: I will use it as I was doing and as I instruct patients to do. (The witness illustrated the use of the atomiser.) The fact that it comes from my mouth is absolutely proof that it has been in my lungs. That answers the question you raised.

Mr. Justice Ridley: Could it not go through your mouth without going into the lungs?—No.

There is no passage, is there?—If you notice what I am doing I take this vapour up one side and air at the other. I am inhaling while I am pressing the bulb. Watch me once more. (The witness repeated the illustration.) When I come to breathe out, a small portion of the vapour comes out with the air. I am coating the mucous lining from the end of my nose into the lungs with that liquid.

Mr. Justice Ridley: There must be a passage there which the vapour could come through at the back of your mouth?—I do not know. It might be done, but I could not do it. One might be expert enough.

Mr. Justice Ridley: If you smoke——

The Witness: You can blow it out of your nostrils; that is right. But if you take it into your nostrils——

Mr. Justice Ridley: You can go one way but you cannot go the other.

Mr. Duke: Yes; that is so. He could not discharge the quantity of vapour and hold it in any receptacle excepting his lungs.

Mr. Justice Ridley: I understand that is his *reason*.

Mr. Duke: That is the reason of it.

Mr. Eldon Bankes: Is that what he says really or is that what you say, Mr. Duke?

Mr. Duke: Yes; that is what I understand.

Mr. Justice Ridley: That proves it must have been in your lungs.

Mr. Eldon Bankes: But his mouth is big enough to hold that quantity of vapour. My friend says there is no other receptacle.

Mr. Justice Ridley: I am only taking down what he says.

Mr. Eldon Bankes: I am quite willing to accept it that that is what he says.

Mr. Smith: Is it a very important point in the merits of an atomiser that there should be a powerful discharge when you press that ball?—In order to reach all the air spaces through the nasal organs and bronchial tubes you must have a good volume of vapour.

I just want to ask you one more question about Oppenheimer's atomiser. Would it be suitable for use with your specific, for instance?—It could be used, but it would take so long to get any amount of it that if your attack was very bad it would undoubtedly fail. It might relieve any mild attack.

You have tested, I think, three other instruments which have been purchased in chemists' shops of a similar kind?—There are several others. This is, I think, counted one of the best.

Oppenheimer's?—Yes.

Taking it shortly, in the case of all those others which you have tested, do the same distinctions apply at least to the same extent?—There are atomisers, and plenty of them, which produce a spray, that we could not use at all. This one and some others produce vapour but *it is* in very minute quantities.

Who manufactures the atomiser for your brother?—It is manufactured by Codman and Shurtleff of Boston, U.S.A.

Are they a well-known firm?—They are.

What is their business?—Manufacturers of surgical instruments.

About how many of these instruments are turned out every month?—We have a standing order of 400 of these sent to me and the same number *sent to* my brother in the States.

Mr. Eldon Bankes: We cannot have the brother's business.

Mr. Smith: Except *so far as it is* in his knowledge.

Mr. Eldon Bankes: He cannot know.

Mr. Smith: He can tell, at any rate, *during* the time that he was with his brother. However, it is not of *very* much importance.

So far as you are *concerned* you say, quite apart from your brother's house, you have 400 a *month* sent to you?—There is a standing order of 400 a month.

What is your sphere of influence at the present time, so to speak?

Mr. Justice Ridley: Sphere of influence is a peculiar phrase, is it not?

Mr. Smith: I think your lordship will understand it.

Over what part of the world do you sell this specific and the atomiser?—We send it in all parts of the world, excepting North America, for the reason that this is the best distributing centre.

London is?—Yes.

Mr. Justice Ridley: Do you send it all from this house at Herne Hill?—I send it from Herne Hill to every country on the globe, except North America.

Mr. Smith: Who deals with the North American demand?—My brother.

Mr. Justice Ridley: 400 atomisers arrive at this house monthly? (indicating photograph on circular).—Yes.

Mr. Smith: How long have you been in London attending to the English and European business?—I came here in August, 1899.

Did you come over to establish the agency?—I *did*.

With the exception of a short visit to the States shortly afterwards have you been here ever since?—Yes, it has been my home.

Where did you open your first office?—At 51, Holborn Viaduct.

When was that?—I opened the office there on August 16th, 1899.

Have you an office in London now?—No; all business is done at Herne Hill.

Who has the profits of the business which is done at Herne Hill?—I have them myself.

How is the account settled as between yourself and your brother?—I purchase everything from him except the rubber bulb and the glass bottle. This rubber bulb is made in London.

And the glass cup?—The glass bottle is made in France.

But all the parts of the atomiser you get from your brother?—My brother.

At what price do you get them?—The instrument without the bulb and without the glass costs me $1.87 cents in Ohio.

What is the relation to cost price of that sum?—I am supposed to get everything at actual cost from the manufacturer excepting medicine.

The medicine is not in the $1.87 *cents*?—*No*; that is not in it at all.

Mr. Smith: How about the payment for the specific? What payment did you make to your brother for the specific?—Do you mean as to the price paid?—Yes.

Mr. Justice Ridley: Is it not made up here in England?—No, made in Ohio; all made by my brother. *This* medicine costs me $14 a quart in Mount Gilead, Ohio.

How much do the indiarubber bulbs and the glass bottles cost you?—The bulbs cost me 10½*d*. each without *this* metal valve (indicating), which costs me in the States 2*d*.

Mr. Justice Ridley: That is in the $1.87 cents?—No; that is not included in the $1.87 cents.

Mr. Smith: It is a small item additional to the $1.87 cents.

Mr. Justice Ridley: I will leave it out then.

Mr. Smith: So that it comes to this, that all the rest of the atomiser, excepting the bulb, the glass bottle, and that little valve, are obtained from your brother?—Yes.

You have told us the price of the indiarubber ball and the glass thing.

Mr. Eldon Bankes: No, he has not told us that.

Mr. Smith: Will you tell me, please, what the price of the glass bottle is?—I am not absolutely certain as to just the exact cost but my recollection is that it is 1½*d*. apiece. Of course, I buy them in great quantities. It is somewhere between that and 2*d*.

Who pays for the carriage of the atomisers from the States?—I do.

In what sized cases do you get them and how frequently?—I get four shipments a month.

That is of the atomisers alone?—The atomisers and medicine.

They come together, do they?—They usually come together.

Mr. Justice Ridley: The medicine comes in those bottles?—The medicine comes in quart bottles.

You fill them up here?—I fill the bottles up here, yes.

Mr. Smith: The specific comes in quart bottles from the States?—Yes.

bottle would last at least two weeks of constant using, four, five, or six times a day.

Can you answer a simple question: Have you ever made any experiment to ascertain the quantity of vapour atomised if you follow these instructions?—I cannot conceive of any method by which it could be measured, it is so small.

Do you see here that you are advocating frequent use of the atomiser?—We insist upon frequent use.

Assuming that this liquid contains cocaine, I ask you, Are you not here advocating the very thing that is likely to produce the cocaine habit in the patient?—My experience proves that it does not.

That is your answer. One other question about the cure. Do you notice here in this passage that you draw a distinction between arresting the attack and curing the disease?—The facts are that mild cases, or many of them, are cured so that they never have another attack, but they are liable to, and much more liable to than persons who never had it.

I am passing through these things quickly that I am going to make points on. On the next page, 7, I ask you for your explanation of this statement; you will see your advice to the patient: "Eat light meals. Never allow yourself to eat until you have a bloated and distressed feeling in the stomach after meals," which is good general advice. "If you are in the habit of using alcoholic stimulants, morphine, opium, or other narcotics, abandon their use." Why do you say that?—Because they are very harmful to persons suffering from asthma especially and very harmful to all persons.

What is the difference in effect between, we will say, opium and other narcotics and cocaine or atropine?—This was written by my brother, you understand; it is not mine.

I quite understand that.—And I suppose he knows what he is saying.

But can you understand any honest man saying to a patient, "Avoid opium and other narcotics," and at the same moment giving him cocaine and atropine; can you understand any honest man doing that?—That is a supposition, and purely so. I do not know that I can give you a definite answer to a supposition of that kind. Our experience proves that it is absolutely harmless. Probably no man in England has used as much of it as I do myself.

These are the documents that are sent out from this private house of yours at Herne Hill?—Yes.

Do I understand that you and your brother are the persons who, if I may use the expression, "sell the articles"?—Yes.

You have two typewriters who look after the correspondence, and you have two bookkeepers who look after the books?—Yes.

And you and your daughter do the selling?—We dictate the letters that come in to our typists.

Is there anybody in the house who has ever had any medical training at all?—Not in connexion with this remedy.

I ask you, if that is so why do you send out the list of questions which the person who desires to have your remedy has to answer?—We send out that list of questions to ascertain whether the patient has asthma or something else.

Have you medical knowledge enough to know that there are very many illnesses, if I may use a general expression, the symptoms of which are precisely the same as asthma, or would appear to the patient to be the same?—It is true that patients themselves are sometimes deceived.

For instance, have you sufficient medical knowledge to know this, that the symptoms of heart disease may be identical practically with the symptoms of asthma?—I do.

So that a patient may think he is suffering from asthma when he is really suffering from heart disease?—Yes.

Is the same thing true of a patient suffering from Bright's disease?—No, I think not.

Have you sufficient medical knowledge to say that?—I have not sufficient medical knowledge, but I have sufficient common-sense to know whether a man has got asthma or whether he has got something else.

I am putting these questions to you and you think that is a reasonable answer. Do you know the disease called emphysema?—Yes, what is called that.

Are the symptoms of emphysema practically identical with those of asthma?—It is true that many medical men speak of an asthmatic as having emphysema as the result of asthma, and the terms are so interchangeably used and confused that they are not very clear.

Then I will not take one that will enable you to have that confusion in your mind. Let me take phthisis; that is a definite disease, is not it—consumption?—Yes.

Are the symptoms of consumption practically identical very often in the mind of the patient with those of asthma?—It is possible that a person may have consumption in a mild form which is not fully developed, and at the same time have asthma.

Is not it true that a person may be suffering from consumption and have symptoms which would make him believe that he was suffering from asthma?—They are very different, but a patient might so think.

That is all I am asking you. Let me take that. A patient may be suffering from heart disease and may think that he is suffering from asthma; a patient may be suffering from phthisis and may think that he is suffering from asthma. The only question you ask him is, not as to his symptoms so that you can judge, but you ask him: "How long have you had asthma?" and then he answers. Now I ask you, Do you suggest to the jury that these questions can in any way assist you as to whether you shall send out this stuff or not?—Sometimes they are so answered that I am in doubt and then I write and ask further questions and I ask them for the opinion of their family physician as to their ailment.

Do you not think that, as stated by one of your witnesses, these questions are calculated to lead patients to believe that they will be submitted to some person of medical knowledge who will be able to say whether the cure is applicable to their case or not?—Those questions were written by a medical man.

Was not the object of sending them out to lead the patients to believe——

No, that is not the object, to deceive them.

I do not know whether it is the object but do you not realise that the effect of that is that patients would believe that those questions were to be submitted to some medical opinion before this cure was sent to them?—It is possible that they might so construe it.

And, as a matter of fact, they would be received into this private house where there is nobody but you and your daughter, who do not profess any medical knowledge at all?—My experience has been that I am able to judge very accurately as to the case when I get those questions answered.

The only case that I can deal with is this man Cashing, because those are the only questions that we have seen or that we know about. Let me ask you to consider what the questions and the answers were? What you state on the top of your paper is: "Dr. Tucker's Asthma Specific, Chief Dispensary, Mt. Gilead, Ohio, U.S.A. Headquarters for Europe: 'Onaway,' Half Moon-lane, Herne Hill, London, S.E. All correspondence should be addressed to A. Q. Tucker, General Manager. This blank to be filled up on both sides and returned." Then you ask the man his name and address and you ask him his age and his occupation. What do you ask him that for, because, according to you, this remedy is applicable to anybody between the age of a few months and any age you can live to—Any man who follows stone-cutting or works in a flour mill or a warehouse is filling an avocation which is liable to develop asthma and aggravate it materially.

Why do you ask his age?—It is not so very important that we should have his age, yet we like to know whether we are dealing with a person in vigour or whether we are dealing with a very old person.

But according to you it is equally applicable and you send it out whether he is three or whether he is 50.—That is right.

Then why ask it?—It is merely to know more about the patient—to get familiar with his case.

Is it because you are following the form which is frequently followed when people try to treat patients by correspondence?—The questions were asked by my brother, the medical man.

By a medical man and to be submitted to a medical man?

MR. DUKE: He does not say his brother has them submitted to him.

MR. ELDON BANKES: Your brother had them submitted to him. He wrote them.—Yes.

And they were a form which he himself used?—Yes.

"Name and address; age; occupation; how long have you had asthma? Do you know the first cause of your asthma? If so, state it. When do you suffer most from asthma, summer or winter? How frequent are your attacks? Are your attacks more severe at night than during the day? What remedy are you now using to relieve attacks?" You have only one remedy, have you?—That is all.

what it costs him; I will not ask in detail, but I will leave it to my friend to cross-examine him and I can develop it, if necessary, when I re-examine him. (*Document handed to the witness.*)

First of all, is that a weekly account taken quite at random?—This is an actual invoice made by my brother dated Oct. 19th, 1907.

Does that fairly represent what an average shipment would be?—This individual one is a little larger than the average and yet very little, too. There are 200 atomisers in this one shipment.

What is the price to you, as shown in the bills, of 200 atomisers?—356 dollars. That does not include the bulb or bottle.

Mr. ELDON BANKES: No, we follow that.

Mr. SMITH: What is the charge there for testing and packing?—$6. That includes the package and the testing and packing.

Mr. JUSTICE RIDLEY: You take a dollar at 4*s*., do you not?—It is nearly that; it is 4*s*. 2*d*.

Mr. ELDON BANKES: I have taken it at 4*s*. 2*d*. and I think it shows that the cost of the atomiser as invoiced to him is 7*s*. 8*d*. or 7*s*. 9*d*.

Mr. SMITH: I have taken it at 4*s*. 2*d*. and I think that is substantially correct.

Mr. ELDON BANKES: Then we agree about that; it is invoiced to him at 7*s*. 9*d*.

Mr. SMITH: I will have that checked; I think it is so.

In the week you have before you I think the amount of specific shipped was 33 quarts and 24 ounces?—Yes.

What is the charge for that?—It is $540, but there is a discount from that of $67 and 50 cents.

How does the discount arise?—That discount arises to cover wastage.

Mr. ELDON BANKES: Need we trouble about it? We only want to get the accurate figures.

Mr. JUSTICE RIDLEY: What does it work out at?

Mr. ELDON BANKES: It works out at 1*s*. 6*d*. an ounce.

Mr. SMITH: I think that is substantially right, but your lordship will not take it for the moment as agreed. I will have it worked out, but I think it is about right.

The WITNESS: The amount of the fluid, 33 quarts 24 ounces, cost to me in Ohio $473.50 cents.

Then there are 36 bottles and corks?—Yes.

What is the figure you have for them?—$6.12 cents.

Then there are the metal valves. There are ten gross of them, I think?—There are no metal valves in this invoice. I think they have got them mixed in some way.

Have you not taken out the metal valves for the same week? If you have not, you will tell me so. Have you not worked it out for the same week?—It is about 3*d*. for these little valves for putting into the end of the indiarubber. They come from the States, all of them.

Have you got the boxes there as coming from the States?—Yes, $5.

And the express to New York?—$8 58 cents.

Mr. Justice RIDLEY: What is that?—Express to New York from Ohio; that is the railroad charges.

What does that give us as a total?—The total is $854 20 cents., that is after deducting the discount on the fluid.

That is not taking into consideration the glass bottles nor the corks?—No.

Mr. Justice RIDLEY: It leaves one with no idea of what the price of each particular article is—not the slightest.

Mr. SMITH: It does in a way.

Mr. Justice RIDLEY: If you can give me the result following from that I shall be much obliged. I have it partly. I have the specific at 1*s*. 6*d*. an ounce, and the atomisers at 7*s* 9*d*. each.

Mr. SMITH: Your lordship sees in respect of those two articles this gives your lordship the price.

Mr. ELDON BANKES: I do not know whether my learned friend would agree to this. Taking all the figures he has given the cost to this gentleman of the atomiser is about 9*s*.

Mr. SMITH: I believe it is almost exactly right.

Mr. ELDON BANKES: Then we need not discuss about it because we can agree.

Mr. Justice RIDLEY: Including the box and the carriage and everything?

Mr. ELDON BANKES: Including everything.

Mr. SMITH: I think that includes everything except the rubber bulb.

Mr. ELDON BANKES: No, that is included too.

Mr. SMITH: Is the bottle from Paris included?

Mr. ELDON BANKES: Yes.

Mr. SMITH: I have not the least doubt that my friend is right, but I have somebody who will check it.

Mr. ELDON BANKES: We can try and agree on a figure.

Mr. SMITH: I have no doubt we shall be able to.

Mr. Justice RIDLEY (to the witness): Will you accept that figure as far as you are concerned?—9*s*.?

Yes.—I think that is very much correct, but the cost of the fluid, I think, is more than 1*s*. 6*d*. The fact is this: a quart of fluid makes 28 ounces and it costs me $14; you can figure it out for yourself. That is without any freight.

Mr. ELDON BANKES: But he sells it by the English ounce.

The WITNESS: There is a difference between the American ounce and the English ounce. The American ounce is a good deal larger than the English ounce. A quart should make 32 ounces—that is the American ounce—but we find by actual experience that it works out at about 28 ounce bottles from a quart.

An English ounce or an American ounce?—An American ounce.

You sell it according to the English ounce, do you not?—No, I sell it according to the American ounce. The bottles are made according to the American standard.

Mr. SMITH: In the estimates you have given me so far you have not dealt at all with working expenses. I want to ask you what your estimate is for working expenses as a percentage on the gross receipts.—Do you mean my office help?

Yes; offices and so forth?—My office help is now £20 per week.

That is very nearly £1000 a year.

Mr. Justice RIDLEY: What does "office help" mean?—There are typists. I have two typists, two bookkeepers, and two shippers.

Mr. SMITH: You keep those pretty busy?—Yes.

You yourself are able to carry on no other business at all?—No; my daughter is also associated with me.

So that is eight of you continuously devoted to the business?—Yes.

In the case of your own time and your daughter's time you cannot put a figure value upon it, but in fact you spend your business time upon it?—Entirely.

Does your brother, apart from any profit he makes on the sale of the specific, charge you anything for European rights?—Nothing at all.

He is your brother and you do not pay him for that at all?—No; nothing at all. He has a small profit on the specific only—nothing else.

In your view is he dealing with you on commercial lines?—He is not.

Have you formed an estimate of the value of the rights you possess?

Mr. ELDON BANKES: I object to that.

Mr SMITH: I submit I am entitled to ask this gentleman who is familiar with the circumstances under which the business is carried on.

Mr. ELDON BANKES: We have the figures.

Mr. SMITH: My friend says we have got the figures, but that is not the point in the least. The point is this: we sell the atomiser and we sell the specific, and one of the points on which they rely is the price we charge for it. I submit I am entitled to get from this gentleman that his brother because he is his brother allows him, free of all cost, rights in this country which have a specific commercial value if they are in the hands of a stranger. I submit I am entitled to do that.

Mr. Justice RIDLEY: I do not think you are. We have to form our own judgment.

Mr. SMITH: I do not know that it is of great importance, but I should submit I was. Here is a case in which a gentleman says, "I get this from my brother; he allows me to sell it without paying anything because he is my brother."

Mr. Justice RIDLEY: That is quite right.

Mr. SMITH: It was rather on those lines I was proposing to ask the question.

Mr. Justice RIDLEY: I *shall* ask the jury to say what they think the value is.

Mr. SMITH: I do not think it is worth pressing in any event.

At any rate, you pay your brother nothing, and you say in your judgment it has a commercial value?—I do; very great bottle would last at least two weeks of constant using, four, five, or six times a day.

Can you answer a simple question: Have you ever made any experiment to ascertain the quantity of vapour atomised if you follow these instructions?—I cannot conceive of any method by which it could be measured, it is so small.

Do you see here that you are advocating frequent use of the atomiser?—We insist upon frequent use.

Assuming that this liquid contains cocaine, I ask you, Are you not here advocating the very thing that is likely to produce the cocaine habit in the patient?—My experience proves that it does not.

That is your answer. One other question about the cure. Do you notice here in this passage that you draw a distinction between arresting the attack and curing the disease?—The facts are that mild cases, or many of them, are cured so that they never have another attack, but they are liable to, and much more liable to than persons who never had it.

I am passing through these things quickly that I am going to make points on. On the next page, 7, I ask you for your explanation of this statement; you will see your advice to the patient: "Eat light meals. Never allow yourself to eat until you have a bloated and distressed feeling in the stomach after meals," which is good general advice. "If you are in the habit of using alcoholic stimulants, morphine, opium, or other narcotics, abandon their use." Why do you say that?—Because they are very harmful to persons suffering from asthma especially and very harmful to all persons.

What is the difference in effect between, we will say, opium and other narcotics and cocaine or atropine?—This was written by my brother, you understand; it is not mine.

I quite understand that.—And I suppose he knows what he is saying.

But can you understand any honest man saying to a patient, "Avoid opium and other narcotics," and at the same moment giving him cocaine and atropine; can you understand any honest man doing that?—That is a supposition, and purely so. I do not know that I can give you a definite answer to a supposition of that kind. Our experience proves that it is absolutely harmless. Probably no man in England has used as much of it as I do myself.

These are the documents that are sent out from this private house of yours at Herne Hill?—Yes.

Do I understand that you and your brother are the persons who, if I may use the expression, "sell the articles"?—Yes.

You have two typewriters who look after the correspondence, and you have two bookkeepers who look after the books?—Yes.

And you and your daughter do the selling?—We dictate the letters that come in to our typists.

Is there anybody in the house who has ever had any medical training at all?—Not in connexion with this remedy.

I ask you, if that is so why do you send out the list of questions which the person who desires to have your remedy has to answer?—We send out that list of questions to ascertain whether the patient has asthma or something else.

Have you medical knowledge enough to know that there are very many illnesses, if I may use a general expression, the symptoms of which are precisely the same as asthma, or would appear to the patient to be the same?—It is true that patients themselves are sometimes deceived.

For instance, have you sufficient medical knowledge to know this, that the symptoms of heart disease may be identical practically with the symptoms of asthma?—I do.

So that a patient may think he is suffering from asthma when he is really suffering from heart disease?—Yes.

Is the same thing true of a patient suffering from Bright's disease?—No, I think not.

Have you sufficient medical knowledge to say that?—I have not sufficient medical knowledge, but I have sufficient common-sense to know whether a man has got asthma or whether he has got something else.

I am putting these questions to you and you think that is a reasonable answer. Do you know the disease called emphysema?—Yes, what is called that.

Are the symptoms of emphysema practically identical with those of asthma?—It is true that many medical men speak of an asthmatic as having emphysema as the result of asthma, and the terms are so interchangeably used and confused that they are not very clear.

Then I will not take one that will enable you to have that confusion in your mind. Let me take phthisis; that is a definite disease, is not it—consumption?—Yes.

Are the symptoms of consumption practically identical very often in the mind of the patient with those of asthma?—It is possible that a person may have consumption in a mild form which is not fully developed, and at the same time have asthma.

Is not it true that a person may be suffering from consumption and have symptoms which would make him believe that he was suffering from asthma?—They are very different, but a patient might so think.

That is all I am asking you. Let me take that. A patient may be suffering from heart disease and may think that he is suffering from asthma; a patient may be suffering from phthisis and may think that he is suffering from asthma. The only question you ask him is, not as to his symptoms so that you can judge, but you ask him: "How long have you had asthma?" and then he answers. Now I ask you, Do you suggest to the jury that these questions can in any way assist you as to whether you shall send out this stuff or not?—Sometimes they are so answered that I am in doubt and then I write and ask further questions and I ask them for the opinion of their family physician as to their ailment.

Do you not think that, as stated by one of your witnesses, these questions are calculated to lead patients to believe that they will be submitted to some person of medical knowledge who will be able to say whether the cure is applicable to their case or not?—Those questions were written by a medical man.

Was not the object of sending them out to lead the patients to believe——

No, that is not the object, to deceive them.

I do not know whether it is the object but do you not realise that the effect of that is that patients would believe that those questions were to be submitted to some medical opinion before this cure was sent to them?—It is possible that they might so construe it.

And, as a matter of fact, they would be received into this private house where there is nobody but you and your daughter, who do not profess any medical knowledge at all?—My experience has been that I am able to judge very accurately as to the case when I get those questions answered.

The only case that I can deal with is this man Cushing, because those are the only questions that we have seen or that we know about. Let me ask you to consider what the questions and the answers were? What you state on the top of your paper is: "Dr. Tucker's Asthma Specific, Chief Dispensary, Mt. Gilead, Ohio, U.S.A. Headquarters for Europe: '*Onaway*,' *Half Moon-lane*, Herne Hill, London, S.E. All correspondence should be addressed to A. Q. Tucker, General Manager. This blank to be filled up on both sides and returned." Then you ask the man his name and address and you ask him his age and his occupation. What do you ask him that for, because, according to you, this remedy is applicable to anybody between the age of a few months and any age you can live to?—Any man who follows stone-cutting or works in a flour mill or a warehouse is filling an avocation which is liable to develop asthma and aggravate it materially.

Why do you ask his age?—It is not so very important that we should have his age, yet we like to know whether we are dealing with a person in vigour or whether we are dealing with a very old person.

But according to you it is equally applicable and you send it out whether he is three or whether he is 50.—That is right.

Then why ask it?—It is merely to know more about the patient—to get familiar with his case.

Is it because you are following the form which is frequently followed when people try to treat patients by correspondence?—The questions were asked by my brother, the medical man.

By a medical man and to be submitted to a medical man?

Mr. DUKE: He does not say his brother has them submitted to him.

Mr. ELDON BANKES: Your brother had them submitted to him. He wrote them.—Yes.

And they were a form which he himself used?—Yes.

"Name and address; age; occupation; how long have you had asthma? Do you know the first cause of your asthma? If so, state it. When do you suffer most from asthma, summer or winter? How frequent are your attacks? Are your attacks more severe at night than during the day? What remedy are you now using to relieve attacks?" You have only one remedy, have you?—That is all.

distinct. He said, "I do not claim that it cures asthma"; then my friend said, "What do you say it cures?"

Mr. SMITH (to the witness): Just take your pamphlet in your hands.

Mr. Justice RIDLEY: He said it does not cure the liability to asthma.

Mr. SMITH: Yes, that is what he says.

Mr. ELDON BANKES: I object to the form of my friend's question. The witness says he does not claim that it cures the liability to asthma. Then my friend says, "What do you claim it does cure?" and his answer is, "I do not claim it cures anything."

Mr. SMITH: It is so easily put right I should not have thought it was worth while wasting time on it at all.

Mr. ELDON BANKES: Then put it right.

Mr. SMITH: Will you look at the first page of the pamphlet, the one that has the illustration. You say here, "Specific for the perfect relief and cure of asthma and hay fever." I will ask you on that, When you call it a cure there in what sense do you say it is a *cure*?

Mr. ELDON BANKES: I object to that. The document speaks for itself and the question is what people receiving this document will understand and not what this gentleman chooses to mean by it.

Mr. SMITH: The submission I make to your lordship and the question I tender is this: Do you cure asthma? I am quite content to take it in that way if your lordship thinks that is a proper question.

Mr. Justice RIDLEY: He says he does not.

Mr. SMITH: I understand so, and then I propose, if your lordship thinks it is a proper question, to ask him: "In what sense do you say on this page it is a cure of asthma?"

Mr. Justice RIDLEY: I think you ought to ask more generally—What other effect does it have on asthma beside relieving and arresting paroxysms?

Mr. SMITH: I am obliged to your lordship; I will put it in that way.

What other effect upon asthma has it than that of alleviating the paroxysm of the attack?—It indirectly has this result: the patient is able to sleep, able to eat, and able to exercise, which renders him much stronger and less liable to a recurrence of the trouble.

What effect would a succession of attacks have upon the rallying power of the patient?—It has a tendency to destroy the rallying power and weakens the patient.

You say by giving relief from the attacks it strengthens them?—It strengthens them by reason of rest and absence of suffering.

You say you have had many years' experience of dealing with asthma, although you are not a *doctor*? *Is* your practical view that asthma is local or constitutional?—Local.

Apart from asthma, do you hold out *your* specific as being beneficial in other more or less *analogous ailments*?—It is equally efficacious in hay fever and a very great relief to nasal catarrh.

I want to ask you about this man, Alfred *Cushing*. *Did* you receive an application from the deceased man, Cushing, on or about the 2nd of February, 1904?—I did.

Is that it? (Document handed to the witness.)—That is the one.

"Occupation?—Fitter. How long have you had asthma?—Seven years. Do you know the first cause of your asthma; if so, state it.—Through having bronchitis. When do you suffer most from asthma, summer or winter?—Winter. How frequent are your attacks?—Very *often*. Are your attacks more severe at night than during the day?—No. What remedy are you now using to relieve attacks?—Cod-liver oil as tonic. Does the remedy generally give you relief?—Yes. During the intervals between the attacks is your breathing perfectly free and easy?—Breath always very short. Do you have nasal catarrh?—Yes. Did you ever have hay fever?—Yes. Do you sneeze often?—No. Do you expectorate much?—Yes. Do you live where malarial fever prevails, or fever and ague?—No. Do you use alcoholic stimulants?—Yes, a little whisky sometimes. Do you use morphine or opium?—No. *Is* your general health good?—Yes." I will hand that up to your lordship. Was it on that form so filled in that you supplied your atomiser and specific to this man, Cushing, on whom the inquest was held?—I did.

Did you send him the atomiser and the specific for trial? He asked for it on trial. I think?—He did.

And you sent it about the 4th of February?—I did.

Did he keep it for a fortnight?—He did.

So that during those 14 days he had the opportunity of judging for himself whether it was beneficial or not?—He did.

At the end of the 14 days what happened then?—He sent in his £3 and we forwarded him two ounces of fluid.

Making up the balance of four ounces?—That was the first instalment.

You sent him two to start with for a trial?—No; we only give half an ounce for a trial—that is a gift.

Can you tell me whether having had his trial, having had the first instalment of the specific, he sent for more afterwards?—He sent for the second two ounces later; I think it was some six months afterwards.

I have a letter here from him to you:

> SIR,—Please find enclosed order for one ounce of fluid. Having had the misfortune to crack my glass that holds the fluid, kindly let me know the cost of a new one.
>
> Yours truly,
> A. CUSHING.

I do not know whether you can tell us about when the date of that application was?—I do not think I could.

Mr. DUKE: Just look and see; there is a memorandum on it. (Document handed to the witness.)—I see written here in pencil about such a date.

Mr. SMITH: Do you know who has written it? If you do not we will get it from someone else.—It is one of my helpers in the office.

Then he will be able to tell us. Do you know of any other A. Cushing on your books?—There is no other.

So that any order that is signed Cushing is from him?—Yes.

I think in the early part of January last you received from correspondents a notice of this newspaper report on the inquest of Cushing?—I did.

I need hardly ask you had you any opportunity of being present at the inquest or did you know that the specific was to be mentioned at the inquest?—I knew nothing about it until in one of my morning's mails I had about half a dozen clippings sent to me by my patrons. That is the first knowledge I had of the inquest.

I want to ask you about your customers. Have you had among your customers, or your patients, I think you call them, medical men?—Oh, *yes*, a good many.

I want you to take your books.

Mr. Justice RIDLEY: I do not think it is necessary for you *to do that now. Let* Mr. Bankes do it if it is necessary. Cannot you take it generally?

Mr. SMITH: May I take it a little more particularly? Can you give me a rough idea of how many medical men there are on your books?—There is something in the neighbourhood of 300.

What proportion of those are in England? My friend can ask you the names if he wants them. Do you know roughly what proportion are in England?—I think less than half are in England. The larger number are on the continent. There are no doubt many more that are medical men, but they have failed to give their title, and we do not know whether they are doctors or lawyers, or who they are.

My learned friend Mr. Duke mentioned Sir Stephen Mackenzie. I want you to tell me, have you supplied any to Sir Stephen Mackenzie?—Yes; he is one of *our* oldest patients. I think it is some six years since he began; five years at least.

The earliest date, I think, is July 1st, 1901?—I think that was the time he got it.

Mr. ELDON BANKES: If you are going into that will you have the book produced?

Mr. SMITH: Yes.

Mr. Justice RIDLEY: You must not take it merely by naming the doctor that I am acquainted with him.

Mr. SMITH: I will ask a question about that. *Who is* Sir Stephen Mackenzie?—I never met him personally. We did our business by correspondence. I understand he is a physician standing very high in his profession.

Mr. Justice RIDLEY: Sir Morell Mackenzie I know.—This is a relative, as I understand.

Mr. SMITH: Whilst the books *are being* produced I will just ask you this question. Is this letter dated Oct. 15th, 1907, from Sir Stephen Mackenzie?

Mr. ELDON BANKES: I object *to that*. My friend cannot possibly put in letters.

Mr. SMITH: It is only an order.

Mr. DUKE: The witness *needs* to have his memory refreshed as to the period of time when Sir Stephen Mackenzie was a customer.

though he would have sold it at one time without a signature; but it may not apply to all chemists.

Mr. DUKE: The particular syrup your lordship is referring to is probably sold without any signature.

Mr. Justice RIDLEY: I could not get it the other day.

Mr. DUKE: I have not tried the other day, but it is not very long ago.

Mr. Justice RIDLEY: It is not quite the same thing. It depends where you go, I daresay.

Mr. ELDON BANKES (to the witness): I put to you a document which you say has only come into existence recently.

Mr. Justice RIDLEY: I suppose we shall have some general question to discuss here about the presence of poisons in these medicines. Then it becomes a question of quantity, does it not, if one may clear the air? Poison is a relative term. Strychnine is a drug properly administered, so is arsenic, and so are all kinds of poisons; it depends on the quantities.

Mr. ELDON BANKES: My evidence is that these poisons are present in this liquid in considerable quantities and my medical evidence is in such quantities that the use of this stuff in this indiscriminate way is a public evil.

Mr. DUKE: That is not the case that is raised on the pleadings.

Mr. Justice RIDLEY: The reason I put the question was it seems to me that the presence in small quantities does not prove that they are deleterious because they are constantly administered in the proper proportion.

Mr. ELDON BANKES: I quite agree.

Is not it the fact on every possible occasion you have always represented to everybody who has asked the question that this treatment of yours is perfectly harmless?—I do absolutely.

I have taken that statement. Now there is the letter to Cushing. You wrote a letter on Feb. 2nd to Cushing saying—

Mr. DUKE: That is not in at the moment.

Mr. ELDON BANKES: I am putting it in. "2nd February, 1904. Your order for a two weeks' trial received and we will forward the outfit to you to-day by parcels post. You will find printed instructions in the box directing you how to use it and so forth." Then at the end he says: "Now, in closing I may urge you again to read and follow the printed instructions sent you in the box. By doing so you will find the treatment both easy and pleasant to use; it is perfectly harmless."

Mr. DUKE: That letter is in.

Mr. ELDON BANKES: Yes, that letter is in. The witness says, and perfectly fairly says, that is what he has always said to everybody.

Mr. Justice RIDLEY: Have you got that letter?

Mr. DUKE: No, that is why I was anxious it should go in.

Mr. Justice RIDLEY: I suppose you have only a copy of it.

Mr. DUKE: If so, my learned friend will have to prove it.

Mr. ELDON BANKES: I can get the original and I will ask the witness if there is any point about it.

While that is being looked for I will ask you something else. You have talked about your business as between yourself and your brother. Do I understand that the parts of the atomiser which come from America and the liquid are both invoiced to you by your brother?—They are.

So that he charges you what sum he thinks proper and you pay him direct?—Yes.

You do not pay the manufacturer of the atomiser but you pay him?—I pay him.

The price which you pay him, I understand, roughly speaking, works out at about 9*s.* for the atomiser and something between 1*s.* 6*d.* and 2*s.* an ounce for the liquid?—It is something over 2*s.*

We will take it for working purposes, without desiring to be absolutely accurate, at about 2*s.* and 9*s.* Would that be about right?—That is about right, but it is a little under.

Therefore your brother is prepared to sell the stuff to you at that price?—Yes.

Do you know that the actual cost of each ounce of liquid is about 3*d.*?—I know nothing about it—absolutely nothing.

So that the position is, if I can prove that the cost of the stuff per ounce is about 3*d.*, your brother charges you about 2*s.*, which is a very fair profit for the cure and everything else, per ounce, and you, as between you and the public, raise that 2*s.* to 8*s.* That is the business view of it, is not it?—No, it is very different from that.

If those are the prices that is the business view?—That is on the supposition that this does not cost anything, or practically nothing.

I am asking you to assume that the liquid can be bought and compounded at about 3*d.* an ounce.—It cannot for any such amount.

I am going to give evidence about it. Assume that, and we know that your brother charges you about 2*s.*; when it arrives here you charge the general public 8*s.*, although, so far as the cure is concerned, you have had nothing to do with that. It is your brother who has invented the cure and has taken the payment for that in the difference between the cost of the stuff and the 2*s.* he charges you. That is a very satisfactory increase of price, is it not?—On that 2*s.* you have to put another 1*s.* for medicine stamps. You have to put on the mailing cases in which it is sent, the bottle in which it is sent, the cost for sending it, and the carriage across over here.

I have included the carriage in the 2*s.*—That does not include it. The actual cost is over 2*s.* in Mount Gilead, Ohio, per ounce.

You have given us some figures as to the business done, and you have disclosed your books to us, and we have had an opportunity of looking at them, and I find that you keep your books in this way, that you have got one column, amount received, and in another column you have got the amount deposited. Does the amount deposited mean the amount you have paid into the bank?—Yes, it does.

Are all your general expenses, apart from what you pay your brother by cheque, paid by you before you pay these amounts into the bank?—They are not; they are paid out of that which goes into the bank.

I see. For instance: for the year 1906, your gross receipts are £19,641, and you paid into the bank £18,301. How do you account for the difference? Are they payments on account of the business?—The difference is made up by the payments in cash by those who call in the office. We receive all the way from £3 to £10 a day direct from our patients who come to the office, but the deposit is just what is deposited in the bank, and that is made up of cheques and postal orders. We turn no cash into the bank.

But you pay a large proportion of your working expenses out of the cash you receive over the counter?—Some parts of it, but most of it is paid out of the banking account. All the money sent to the States is sent by New York draft through the bank.

That appears in your pass-book, does not it?—Yes.

I have had that taken out. Is it accurate that you received over here in England, gross £19,641, or thereabouts?—I do not know what I did pay him in any one year.

Would you say about £5600?—Yes; it is probable that it is pretty nearly the thing.

About right?—I do not know; it may be or may not.

If that is right the difference represents the increased cost which you put upon the article over and above what you paid your brother for it?—No, it would not.

Not altogether?—No. Here is an item that I pay: from £40 to £60 a month for these rubber bulbs.

I quite agree; and the bottles?—Yes; I pay from £10 a month for bottles, the glasses, and we have all the mailing cases in which this fluid is sent through the country; they mount up to a large sum. The amount that is sent to my brother does not cover nearly all the expenses by any means; the materials that enter into it I do not get from him.

As to this gross amount of £19,641, are the agents' commissions deducted from that before it is entered into books?—They are all included in that up till quite recently. I think it is only some eight or nine months since they were not included. Up to within the last eight or nine months all the commissions were included in the £19,000.

May I take that the relative year's trading in the year 1906 the gross figures £19,641 did include the agents' commission?—Yes.

But the figures which have been given us for 1907 do not include it?—Since May, I think, or about that time, we cut them out. You understand that our business is run presumably on a cash basis although we cannot quite make it so. Secondly, we do not keep a debtor and creditor account. The only accounts we have up till May are the gross receipts and the amount of money that I sent out, and there has been no account kept of the expense, but since May I have been keeping an accurate account of all expenses as well as income.

Mr. ELDON BANKES: Mr. Smith gave us the figures of

Are you prepared to dispute that both those are poisons scheduled to the English Pharmacy Act?—I do not know much about the Pharmacy Act; I do not know that I ever read it.

Listen, Sir, do you defend sending out indiscriminately these enormous quantities of this liquid without either inquiring what the constituents are or what harm they will do in certain cases?—I do.

Now let me ask you a word as to the method in which you carry on business. I understand it is carried on at this private house at Herne Hill?—Yes.

Does your name appear in the Directory?—In the neighbourhood directory it does.

In the London Directory?—I do not know whether it is a general directory of the whole city or not.

Do you insert your name anywhere in any commercial directory?—No; I think it may be in the telegraphic directory.

You do not let anybody know publicly that you are carrying on business?—No; we do not advertise at all.

You do not advertise at all in the public press?—No.

Is that because you do not desire public attention to be directed to what you are doing?—We do not think it pays in the first place, and in the next place we have no occasion to do it.

I am coming in a moment to what you do. You have not inserted your name anywhere in any commercial directory?—No.

And you do not advertise in the public press?—No.

But what you do, as I understand, is to send out large numbers of these pamphlets?—Only in response to inquiries.

Have not you agents who are distributing these?—Only when they are written to in regard to it. Instead of writing a letter they send the printed one in the first part of this book; it is merely to save the trouble of writing letters, that is all.

About how many copies have you had in each edition of this pamphlet?—The last edition was, I think, 25,000.

So that you have issued these pamphlets and you have now arrived at the fifth edition?—I think so, the fourth or the fifth.

Has each edition been 25,000?—No; only the later ones have been thereabouts.

So that somehow or other you have been issuing these things to the extent of four editions, amounting to many thousands of copies?—Yes.

You desire people to read this to ascertain what it is you have got to sell them?—We give them this to save writing a long letter explaining our theory of the treatment.

This opens with a picture.—Yes.

And it is headed "Nathan Tucker, M.D."—Yes.

Is that a picture of Nathan Tucker or a picture of you?—No, it is Nathan Tucker.

Is not this a picture of yourself?—No, it is not.

You are very like each other.—Yes, in some respects.

In appearance, may I say. Who wrote this; did you write it, or your brother?—The article following the picture?

The pamphlet, yes.—The first part of this is written by my brother.

I want you to turn to page 6. Do you find on page 6 in the second paragraph, "Asthmatics who have organic heart disease or weak heart action can use the remedy with perfect safety"?—Yes.

Have you sufficient medical knowledge to know that that is an absolutely incorrect statement having regard to the fact that this contains cocaine?—I know that this is absolutely true from experience, and it is the statement of my brother, not mine.

Never mind; it is you who issue this in Europe.—I publish this in Europe.

You take the responsibility for publishing it?—This is published as an article written by Dr. Tucker.

And it is issued by you in order to encourage the sale of the specific in England?—Yes.

On page 7 with regard to this you say: "The advice frequently given, 'Physician, heal thyself,' has been accomplished in this instance, and we now offer to suffering humanity the result of 20 years' experience which has finally worked out a cure for asthma and hay fever as well as all other catarrhal diseases of the air-passages." Are you there claiming for this that it effects a cure of asthma?—A cure in one sense and not in another—not a cure to any liability to it.

Have you explained anywhere in this pamphlet the sense in which you there use the word "cure"?—We would not regard it as much of a compliment to a man's judgment to explain to him that this remedy is not designed to cure the tendency of the disease of asthma.

This is the document which you send out, by which, I suggest to you, you claim that it cures asthma?—We claim that it cures the attack and it cures to a certain extent the recurrence, but a severe cold will develop it just as quickly as it did before.

Let me read again what you say: "We now claim"—that is you and your brother?—The word "we" is used by my brother in the sense that it is frequently used by writers.

"We now offer to suffering humanity the result of 20 years' experience which has finally worked out a cure for asthma." I ask you, Would not any person reading that understand that what you were offering him was not a relief from paroxysms but a cure for his disease?—I understand that you cannot cure any disease unless it is small-pox or measles so that you cannot develop it again, and we never claimed to. It would be simply absurd to claim such a thing.

There is another document you send out, is there not, the document which you call the instructions?—Yes.

I want to ask you a word or two about that. This is the directions for use, is it not? If you turn to page 5 you will see the instructions: "How to fill the lungs with vapour."—Yes.

You say: "How to fill the lungs with vapour in order to arrest an attack of asthma is the all-important question, which is easy of accomplishment when understood, yet we have had no little trouble in some instances to get patients to comprehend it. The first step in the operation is to first exhaust all the air from the lungs. In order to simplify the balance of the process I will ask you a simple question, which is as follows: Did you ever expand the lungs by closing the mouth and commence drawing in air slowly through the nose until you have filled the lungs with their utmost capacity? If so, this is just what I want you to do, but while you are doing this you are at the same time to be pumping in vapour with the inhaler into one nostril, so that while air is being taken in it carries the vapour along with it into the lungs. This is all there is of the treatment in a nutshell. When the lungs are filled with air and vapour take the instrument from the nose. Now as you expel the air from the lungs you will notice quite a cloud of vapour escaping from the mouth. The vapour which escapes is the surplus that has failed to lodge in the air passages and is also a test that the vapour has reached the lungs. If you are unable to see any vapour escaping from the mouth you may know, to a certainty, that there is no vapour in the lungs to be expelled and that you have failed to inhale properly. Now repeat this process, the next time through the other nostril, and thus continue to do until relieved. You will find, if you stop inhaling, a little short of perfect relief, the spasm will gradually subside. Some can succeed better in filling the lungs with vapour by stopping one nostril with the finger while inhaling through the other side. The length of time required in using the Atomizer in order to get relief will vary from two to five minutes, according to the severity of the attacks. Please do not cough while inhaling, but wait until the spasm yields. In a short time you will expectorate without any effort. Coughing always aggravates asthma and should be suppressed, which is easily done, as the vapour is non-irritating. Coughing tends to keep up the irritation, just what we want to avoid. You are to use the Atomizer four times daily, whether you have asthma or not and as many times oftener as may be necessary to relieve the attacks. You will notice by the above instructions that it is necessary for the vapour to reach the lungs in order to arrest the attacks, heal the mucous surfaces, and cure the disease. Also remember that the more vapour you get into the lungs at one expansion the quicker you will get relief. You ought to be able, by practice, to compress the bulb from three to five times with one long drawn inspiration and not to breathe out during this time." Have you ever made any experiments to ascertain the quantity of liquid which will be passed into the nostril of the patient if he follows your instructions?—It would be so infinitesimally small that you could not estimate it.

Have you ever made any experiment to try?—I use it myself daily and have for 17 years on an average at least four times a day.

Have you ever made any experiment which will enable you to say the quantity of liquid which is atomised if you follow the instructions here detailed?—The amount of fluid in the that proprietary article, and therefore I make that remark. I wish people would be more accurate when they report what I say. Of course, it has nothing to do with the case, but I wish just to say that.

AUGUSTUS QUACKENBUSH TUCKER, *recalled, further cross-examined* by Mr. ELDON BANKES.—I wanted to ask you a few more questions about these atomisers. Have you your atomiser here?—Yes.

And the one you produced yesterday, Oppenheimer's?—Yes.

Did you buy that?—I bought one, but I do not think this is the one.

You can tell me, I daresay, what the retail price of that is?—The one I bought was six or seven years ago. I think it was 6*s.* 6*d.* or 7*s.* 6*d.*, but I will not be sure which.

6*s.* 6*d.*, I suggest to you?—I think perhaps that was it.

In regard to that atomiser, I will ask you about one or two more in a moment; I do not want a great number—that one does produce, does it not, as fine a vapour as yours?—I think it does—sufficiently fine at least.

And the only complaint that you make about it, as I understand, is that each compression does not vapourise so much liquid?—Well, that is true there is but little vapour produced.

Have you ever tested them to see exactly what the difference between the two is in that respect?—Yes, repeatedly.

I suggest to you that the difference is this, that in 100 compressions of yours which would vaporise 0·60 of liquid, Oppenheimer's in 100 compressions would vaporise 0·40?—I do not know about that.

Mr. DUKE: That is two of Oppenheimer's and three of his, to put it simply, if I understand the formula.

Mr. ELDON BANKES: It requires more compressions of Oppenheimer than it does of his.

The WITNESS: I should say Oppenheimer would produce not more than one-fourth of what ours does.

That is your idea?—That is my opinion about it.

Assuming the figures are such as I suggest, would it make any difference at all to the patient?—Decidedly.

Mr. Justice RIDLEY: If they were 0·40 to 0·60?

Mr. ELDON BANKES: Yes, in 100 compressions, your lordship will see.

Mr. Justice RIDLEY: I do not know how you get a percentage; it is not a percentage of anything.

Mr. ELDON BANKES: Of a grain of fluid.

Just let me ask you to look at these two; these are quite sufficient for my purpose. Are you familiar with the atomisers that are sold by Rogers in *Oxford-street*; have you seen those before, or similar ones? (Two atomisers handed to the witness.)—I have seen something similar, not exactly the same. I have seen every principle of every atomiser that has ever been made, I think, but not all of different individuals. There are hundreds of them.

Have you ever tried those?—No, I never tried that.

That produces a very fine vapour, does not it?—I will tell you better in a moment.

You had better take a piece of blotting paper if you want to try that.—No, not blotting paper.

Well, sterilised paper?—Ordinary writing paper.

Mr. Justice RIDLEY: Try the Government paper; that is the best of all.

The WITNESS (after trying atomiser): That is a vapour: it is all right.

Mr. ELDON BANKES: Now try the other one in the same way if you like? (The witness did so.)—That seems to be all right, too.

Just hold that up; that is a very powerful one, is it not?—Yes.

And as powerful as yours, apparently? It is your liquid, I think, in that?—No, that is not mine.

I beg your pardon, but that is one of the same specific gravity?—The only test would be that the same liquid should be in both.

I quite agree. If you have any of yours we will put it in.—I have not any right here.

Just send for a little of yours and we will empty it in. Whilst they are fetching that let me ask you this: Your atomiser consists of two parts; that is to say, there is the sprayer and the vaporiser?

Mr. Justice RIDLEY: Can you identify the second one produced?

Mr. ELDON BANKES: Yes, it is Rogers'; there are two of Rogers'. I have not bought any quantity. The gentleman fairly enough says there are any number of them made. This is one of your own. You put *this* on the top of yours and screw it on in order to create the vapour?—Yes.

If this is taken off and then compressed there is a very much larger amount of liquid which will come through the orifice?—It throws a spray of a large quantity of liquid.

Have you ever seen any of your patients using it in that way?—I never did.

It has never come to your knowledge?—No; but I have no doubt some of them have done it.

Of course, if they do that they will be able to inhale a very much larger quantity of liquid?—They will fill their nostril full and it would not go down into the bronchial tubes at all.

Without any warning that this contains cocaine or any dangerous poison, if a patient got relief from it he would naturally think, when you have told him it is perfectly harmless, that the more he could take the better?—He would not get it past his nostril if he used the spray.

But inhaling it in that way it would pass into his system?—Not to any extent; it would run right back out of his nostril; it would be a douche; that is what it would amount to. He would not get as much into his system as he would by using the other.

Have you got your own liquid now?—Yes.

Have you filled it?—This is our own. (The witness demonstrated.) It does not produce anything like the volume that it did before.

Mr. DUKE: That is to say, it would produce with the other liquid a large volume, but with yours it will not produce so much?—There is much less volume of vapour with this fluid than with the other.

Mr. ELDON BANKES: I cannot see from this distance.

The WITNESS: Well, you could see the other, could not you?

Mr. ELDON BANKES: Yes.

Mr. Justice RIDLEY: Now try your own and let us see. Would not that be fair?

Mr. ELDON BANKES: Yes.

The WITNESS: (After demonstrating.) This throws a stronger volume of much more force. If I may be allowed to explain, I can show you the essential difference in these instruments. These instruments produce the vapour in the chamber; the other instruments produce the vapour in the bottle and the amount of pressure that you get throwing out the vapour is simply the pressure of the vapour, a sufficient quantity of it in the bottle forces itself out by pressure, and that constitutes the principal difference in these instruments.

Is not this the fact? You see this yourself; it has got a bend in it. When you compress this you force the spray, as I will call it—the air pumping into the bottle creates a spray?—It creates a spray in the chamber, not in the bottle.

And then it is forced up, and the point of contact in yours is this point (indicating)?—Yes, that angle.

And the spray is changed into vapour at that point. It is the point of contact that reduces the volume of it and turns it from spray into vapour?—You are correct in that only that there are two angles that it strikes instead of one.

It is quite an immaterial point, but as you have put it to me I suggest to you that one of the disadvantages of yours as against this is this: that if you have your point of contact in the nozzle, and the patient is blowing very hard, it is quite possible that some of the spray passes through the nozzle: if you produce the vapour in the bottle there is no chance at all of the spray passing through the nozzle?—You are correct in this in so far if the instrument is not in proper condition it would be possible to throw a spray out of that nose-piece up *here*. That is quite true, but the instrument would not be working properly if it did so.

But if the spray is produced in the bottle that disadvantage is avoided?—Yes; but you could get no force.

Very well, that is your point. Do you not in some of your papers—I cannot put my hand on it for the moment—represent that this liquid is quite safe because such small quantities of it are inhaled, and as proof of that you call attention to the fact that if you press the vaporiser against a piece of paper as you did just now no mark is made. Do you state that in some of the papers you sent out?—I do not just put it in that shape, but it is a fact. It is true that the infinitesimal quantity, even were it a deadly poison, would be harmless used in such small quantities.

This is what I am alluding to. This is what is said in this paper you told me yesterday you had recently had and sent out recently: "There is one thing that is not considered by

Then what does it matter whether the attacks are more severe at night than during the day if you give the man the same thing whatever his answer is?—Because it brings out one characteristic of the patient's condition. Nearly all asthmatics are worse at night than during the day, but if it comes out that they are worse during the day than during the night it brings out this fact, that exercise has something to do with it.

What does it matter to you, because you have the same instructions how to use the thing for everybody, and you give everybody the same stuff?—But supposing I find by these questions that the patient evidently does not have asthma at all, I then write to him and say, "This remedy will probably do no good whatever."

Your question is, "How long have you had asthma?" Supposing he said, "I have never had it." I do not know, but perhaps you would say, "I shall not send you my stuff," but, if he says, "I have got asthma," what possible ground is there for asking whether he has it more in the night or more in the day, except this, to lead him to suppose that somebody is going to look at this who will vary the treatment according to his answers?—You cannot get a direct diagnosis of an asthmatic's condition without just about those questions, and they do bring it out.

What is the good of a diagnosis to you if you are going to give every man the same stuff and give him the same quantity?—It is a question of whether we give it to him at all or not.

The answer this man gave you to your question, "What remedy are you now using to relieve attacks?" is "cod-liver oil as a *tonic*." If you had been a medical man would not that indicate to you that this man was probably suffering from consumption and that some medical man had ordered him cod-liver oil because he was *suffering from* consumption?—I always expect, when I find a man is taking cod-liver oil, he is in a very much run-down condition and is being fed up.

One of the grounds on which you would feed a man up would be that *he is suffering from* consumption?—Yes.

Let me understand you. Here is a man who says he is suffering from asthma. You told me yourself he may believe he is *suffering from* asthma *but* is really suffering from consumption. You are told he is being fed up with cod-liver oil. You tell me you do not think your treatment is suitable for a consumptive patient, but you sent him this and charged him £3 for it, knowing he was a fitter.—A fitter? I do not understand the term.

Well, a man earning weekly wages. Do you attempt to justify that?—This man was sent this remedy for a two weeks' trial and then he was to decide whether he wanted it or not, and it did not cost him one farthing.

Now I will ask you about the two weeks' trial. Do you know that the effect of cocaine is to deaden the mucous membrane?—I do not know.

Let me understand. Supposing a man suffers from these paroxysms of breathlessness, or whatever it is, and you administer cocaine to him, it will probably relieve him, although it may do him great harm in other respects. Do you follow that?—Yes.

So that if you give a man a fortnight's trial you know that the effect of this deadly drug will be to give him relief and you do not care the least whether it is ultimately going to hurt him or not?—The facts are that it never has injured a solitary man yet; not one.

So you say.—Well, find one if you can; bring him in out of the 25,000.

You must wait until I come to my evidence. The fact is, this man died, an inquest was held upon him, and the fact was proved that he died of long-standing phthisis.—That is the report, I understand.

And it was that fact, was it not, that you had supplied this treatment at £3 to this man which led to the remarks of the coroner, which in their turn led to our remarks?—I do not know what led to your remarks.

Very well, we will see. There is one other document. Is that a document which you circulate in England (same handed to the witness)?—This was sent to me very recently and I have sent it out in a *few instances* when this question was raised in answer to the query as to what was in it. Sometimes our patrons want to know, and they say they have been told it contains certain things detrimental to health, and instead of writing a long letter I inclose this.

You composed it?—No; *my brother* composed it.

Was that sent because you had heard it suggested that your specific contained cocaine and other drugs?—This was written by my brother, printed in the States, and sent over here I think about a year ago. That was the first time I had ever seen it. It was to obviate the difficulty of writing long letters explaining effects of the medicine, if there was any bad effect. I do not think there have been more than 40 or 50 of those *ever left the office. It is possible there may* have been that many. It is only in answer to inquiries that that has been sent out.

This is what your brother apparently says: "We are occasionally asked the question, 'Will the continued use of the asthma remedy produce any injurious effects?'" Have you ever heard it suggested that the continued use does produce injurious effects?—I never did.

So that this is some complaint that has been made to your brother that has not reached you?

Mr. DUKE: He does not say it is a complaint; he says it is an inquiry.

The WITNESS: The question is raised by the suggestion of some party who evidently is jealous of the success of this remedy.

Mr. ELDON BANKES: That is what you think. It was their suggestion that it would, if used continuously, have bad effects?—That suggestion goes out, people become nervous, and they write in asking questions about it.

Have you heard of this suggestion before this case?—Yes.

You have often heard of it?—Oh, yes; it has been at work ever since we started.

You choose to put it down to jealousy?—I do.

But you have heard the suggestion that the continued use of your treatment does produce bad effects?—That question has been *raised* and it has been hinted that that is the effect by jealous parties who are interested to curtail the sale of it.

Do you know that this *specific* of yours has been the subject matter of discussions at meetings of medical men?—I know it has.

Do you know it is commonly known in the medical profession for some time that this specific of yours contains *poisons—among some medical* men?—I know there are some few medical men who have sought to criticise it and actually put the idea that it was a dangerous remedy.

But it has come to your ears, has it not, that amongst certain members of the medical profession it has been known for some little time that it contains cocaine?—They say it has; I do not know.

But you have heard that?—Yes, I have heard it.

Do you really *say* that hearing the statement some time ago that it contained cocaine you have never taken the trouble to have the stuff analysed?—I do, emphatically.

Have you never taken the trouble to ask your brother whether it did contain cocaine?—I never did.

Is that because you were anxious not to know what it contained?—I have nothing to do with compounding it in any way or shape. My side of the business is simply commercial and my brother's is the medical.

To sell things which, if they contain cocaine, would bring you within the Pharmacy Act?

Mr. DUKE: It is a question of law as to the quantity; whether a certain element, cocaine or other ingredients, such as mentioned would bring a person selling a preparation of this kind within the authorities depends on the amount.

Mr. Justice RIDLEY: I discovered accidentally that a chemist who would supply you with a patent medicine without question a year ago would not supply *it now* without your signing a paper.

Mr. ELDON BANKES: There is no alteration in the Pharmacy Act.

Mr. Justice RIDLEY: But there is in the way it is administered.

Mr. ELDON BANKES: It is only because it has become known *that some* of these medicines contain these poisons.

Mr. Justice RIDLEY: The medicine I mean *contains* strychnine and it was known years ago—everyone knew it, Fellows's *Syrup of Hypophosphites. People* constantly buy it, and a most useful thing it is, I believe. It certainly contains *strychnine*. I was talking to a medical man about it the other day. Therefore, I thought people were more strict about it now.

Mr. DUKE: It very possibly is so; I do not know how that is. Of course, if the *fact* be that this gentleman must employ a chemist to sell these things, he must employ a chemist.

Mr. Justice RIDLEY: A chemist will not sell it to you now, Do they or not give up the use of your brother's preparation after having tried these others?—I do not know that any of them have given up ours to use others, but I know they have tried it out of curiosity and dropped it at once.

How long will one of your atomisers last?—Some of them have been in use six or seven years; it depends altogether upon the user. Some people will take care of things and others do not.

If a man has got your atomiser first he will not want a new one?—No. The average length of the life of the atomiser would be at least five or six years, and in many cases twice that.

Mr. DUKE: With regard to the fluid, that exhausts itself in use, of course?—Yes.

And you charge a very large price, as it is said, 8*s*. an ounce, for the new supplies of the fluid?—Yes, after the first four ounces.

Do you find that your customers, in spite of the suggestion there is that there are others as good, continue to deal with you for the expensive article that you supply?—They do. In a very few instances I have had them ask me to reduce the price or they would have to resort to some of these imitations. I have told them to try them, and that has always been my answer.

Have you found some of them have tried them?—They have tried them, but they have not tried them very long.

They came back to you?—Always came back.

We have one or two witnesses here to deal with that matter. My learned friend referred to your books. Did you produce everything relating to your business to the defendants in this action?—Everything that was asked for.

In order that they might see how your business was carried on?—Yes.

The information that my learned friend has been putting to you has been the information which you supplied him with?—Yes.

My learned friend asked you about a good many of the atomisers. Do you know that in the course of the interlocutory proceedings with a view to this trial the defendant was asked to say what the atomiser was which he relied upon as competing with yours, and he was unable to do it?

Mr. ELDON BANKES: That was not right, was it; I think the question was not allowed?

Mr. SMITH: It was resisted.

Mr. ELDON BANKES: It was resisted; I mean to say we said it was not a relevant question.

Mr. DUKE: The substance of the matter is you have had no opportunity of making any test except the rough test in the witness box of these other atomisers, with your brother's atomiser?

Mr. ELDON BANKES: Yes, he has, Oppenheimer.

Mr. DUKE: Oppenheimer he has, but the others which my learned friend has produced have not been brought to your notice before?—I have tried a great many different atomisers that have been presented as a curiosity, but I never saw one that I would take as a gift.

My learned friend says, and you told him, the fact is you have no medical training. Have you ever, in the course of carrying on this business, pretended that you have had any medical training?—Never.

With regard to the questions you ask, my learned friend pointed out that there were questions and that there was only one treatment. Does the pamphlet and do the instructions state in the clearest way that it is only one treatment?—Yes.

That there is an inhaler and a fluid the character of which is decided beforehand?—Yes.

Do you think it is possible that anybody who had read the pamphlet or read the directions could suppose that there was any alteration in the treatment possible on your part?—No.

Then my learned friend asked you about the relative symptoms of consumption, Bright's disease, and heart disease. Have you ever suggested to anybody that this specific would have any effect upon a case of Bright's disease?—Never any beneficial effect whatever.

Or on consumption?—No.

Or on heart disease?—No. We always tell them it will not, and that is why we say it would give them no permanent benefit, but it may give them a trifle of relief.

Suppose a consumptive patient who had a catarrhal condition of his throat and lungs: do you know what would be the effect of his inhaling the vapour?—It would be beneficial so far as the catarrh trouble is concerned, but it would be no benefit to tuberculosis or consumption.

It would relieve the catarrhal trouble, but it would not relieve the permanent disease?—That is so.

Have you ever said that it would?—No.

With regard to the paragraph on page 6 of the pamphlet, my learned friend asked you whether it was true, as I think your brother says: "Asthmatics who have organic heart disease or weak heart action can use the remedy with perfect safety. In fact, if the heart is sound when first commencing treatment, asthma will never be a cause in the development of heart disease for the reason that the specific will keep the asthma under perfect control." You say that you knew from experience that that was the fact?—Yes.

Was that limited to your own personal experience or to your knowledge of other persons who have used the specific?—It is my own personal experience and my observation of the public generally.

My learned friend cross-examined you upon the question of a cure. Except in the sense of preventing an impending attack or dispelling an attack which was actually in progress is there any cure of the liability to asthma?—No, there is none; we never claimed it.

But the attack you say is cured?—Yes.

It can be warded off when the symptoms are shown or it can be stopped when it is in progress?—Yes.

I will not take up time in reading it, but I think on page 11 you call attention to that matter?—Yes.

You say "The treatment will give almost immediate relief and completely arrest the attacks, and by persevering," and so on?—Yes.

Then with regard to the instructions, your brother says in his instructions: "If you are in the habit of using alcoholic stimulants, morphine, opium, or other narcotics, abandon their use. Smoking is also a source of irritation, particularly in closed rooms, and is liable to bring on an attack of asthma." That is on page 7 of the instructions. My learned friend asked you whether you could understand any honest man saying that when he was going to propose the present specific for use in asthma. Tell me, with regard to that, are you able to say from your experience what the effect upon the asthmatic tendency is of the use of alcoholic stimulants?—It is a very decided injury to an asthmatic.

It provokes?—It provokes an attack.

Is it the same with regard to these other matters that are mentioned?—Yes.

Do you think there is anything dishonest in telling people that?—No.

Mr. ELDON BANKES: Morphine and opium I said.

Mr. DUKE: I will come to the others, morphine and opium. Do you know of your own knowledge whether the use of morphine, opium, and other narcotics has any influence in asthmatic cases?—They injure the general health of the patient and render him much more liable to attacks.

Those are your brother's directions, but so far as you are concerned in the sending out of those directions do you see anything dishonest in it?—I never could discover it, no.

I think my learned friend rather suggested that you concealed your identity from public knowledge. Is there any truth in that?—Not the least.

And in fact is it true, as you told my learned friend in answer to an earlier question, that you have sent out in this country many thousands, four or five editions, of this pamphlet, upon the face of which there is a picture of your residence with your name and address at the foot?—Yes.

And a complete statement inside of the whole business?—Yes.

In fact, as you told my learned friend, you have not advertised in the newspaper press?—I have not.

I think the only other matter I need trouble you about is the price which you have charged for this remedy and the profits you have made. In the first place, have you ever charged the patient any more than you told him you were going to charge him in the particulars?—I never did.

And, in spite of the charges, do the purchasers come on and repeat their orders?—Yes.

With regard to your dealings with your brother, do you know what relation the price he charges you bears to the price he charges the general public?—My understanding is that I pay him——

I ask you if you know. Do you know what prices your brother charges the general public in the United States?—Yes, I do.

That is all I want to know. What does he charge them?—He charges them 12½ dollars for what I furnish for £3, but he has no medicine stamps or revenue stamps to put on it.

Then what does it matter whether the attacks are more severe at night than during the day if you give the man the same thing whatever his answer is?—Because it brings out one characteristic of the patient's condition. Nearly all asthmatics are worse at night than during the day, but if it comes out that they are worse during the day than during the night it brings out this fact, that exercise has something to do with it.

What does it matter to you, because you have the same instructions how to use the thing for everybody, and you give everybody the same stuff?—But supposing I find by these questions that the patient evidently does not have asthma at all, I then write to him and say, "This remedy will probably do no good whatever."

Your question is, "*How long have you had asthma?*" Supposing he said, "I have never had it." I do not know, but perhaps you would say, "I shall not send you my stuff," but, if he says, "I have got asthma," what *possible ground* is there for asking whether he has it more in the night or more in the day, except this, to lead him to suppose that somebody is going to look at this who will vary the treatment according to his answers?—You cannot get a direct diagnosis of an asthmatic's condition without just about those questions, and *they do bring it out*.

What is the good of a diagnosis to you if you are going to give every man the same stuff and give *him the same* quantity?—It is a question of whether we give it to him at all or not.

The answer this man gave you to your question, "What remedy are you now using to relieve attacks?" is "cod-liver oil as a tonic." If you had been a medical man would not that indicate to you that this man *was probably* suffering from consumption and that some medical man had ordered him cod-liver oil because he was suffering from consumption?—I always expect, when I find a man is taking *cod*-liver oil, he is in a very much run-down condition and is being fed up.

One of the grounds on which you would feed a man up would be that he is suffering from consumption?—Yes.

Let me understand you. Here is a man who says he is suffering from asthma. You told *me yourself* he may believe he is suffering from asthma but is *really suffering* from consumption. You are told he is being *fed up with* cod-liver oil. You tell me you do not think your treatment *is suitable* for a consumptive patient, but you sent him this and charged him £3 for it, knowing he was a fitter.—A fitter? I do not understand the term.

Well, a man *earning* weekly wages. Do you attempt to justify that?—This man was sent this *remedy for a two* weeks' trial and then he was to decide whether *he* wanted it or not, and it did not cost him *one farthing*.

Now I will ask you about the two weeks' trial. Do you *know that* the effect of cocaine is to deaden the mucous membrane?—I *do not know*.

Let me understand. Supposing a man suffers from these paroxysms of breathlessness, or *whatever it is*, and you administer cocaine to him, it will probably *relieve him*, although it may do him great harm in other respects. Do you follow that?—Yes.

So that if you give a man a fortnight's trial you know that the effect of this deadly drug will be to give him relief and you do not care the least whether it is ultimately going to hurt him or not?—The facts are that it never has injured a solitary man yet; not one.

So you say.—Well, find one if you can; *bring him* in out of the 25,000.

You must wait until I come *to my* evidence. The fact is, this man died, an inquest was held upon him, and the fact was proved that he died of long-standing phthisis.—That is the report, I understand.

And it was that fact, was it not, that you had supplied this treatment at £3 to this man which led to the *remarks of* the coroner, which in their turn led to our remarks?—I do not know what led to *your remarks*.

Very well, we will see. There is *one* other document. Is that a document which you circulate in England (same handed to the witness)?—This was sent to me very recently and I have sent it out in a few instances *when this* question was raised in answer to the query as to what was in it. Sometimes our patrons want to know, and they say they have been told it contains certain things detrimental to health, and instead of writing a long letter I inclose this.

You composed it?—No; my brother *composed it*.

Was that sent because you had heard it suggested that your specific contained cocaine and other drugs?—This was written by my brother, printed in the States, and sent over here I think about a year ago. That was the first time I had ever seen it. It was to obviate the difficulty of writing long letters explaining effects of the medicine, if there was any bad effect. I do not think there have been more than 40 or 50 of those *ever left the office. It is possible there may* have been that many. It is only in answer to inquiries that that has been sent out.

This is what your brother apparently *says*: "We are occasionally asked the question, 'Will the continued use of the asthma remedy produce any injurious effects?'" Have you ever heard it suggested that the continued use does produce injurious effects?—I never did.

So that this is some complaint that has been made to your brother that has not reached you?

Mr. DUKE: He does not say it is a complaint; he says it is *an inquiry*.

The WITNESS: The question is raised by the suggestion of some party who evidently is jealous of the success of this remedy.

Mr. ELDON BANKES: That is what you think. It was their suggestion that it would, if used continuously, have bad effects?—That suggestion goes out, people become nervous, and they write in asking questions about it.

Have you heard of this suggestion before this case?—Yes.

You have *often heard of it*?—*Oh, yes*; it has been at work ever since we started.

You choose to put it down to jealousy?—*I do*.

But you have heard the suggestion that the continued use of your treatment does produce bad effects?—That question has been raised and it has been hinted that that is the effect by jealous parties who are interested to curtail the sale of it.

Do you know that this specific of yours has been the subject matter of discussions at meetings of medical men?—I know it has.

Do you know it is commonly known in the medical profession for some time that this specific of yours contains poisons—among some medical men?—I know there are some *few medical men* who have sought to criticise it and actually put the idea that it was a dangerous remedy.

But it has come to your ears, has it not, that amongst certain *members of the medical* profession it has been known for some little time that it contains cocaine?—They say it has; I do not know.

But you have heard that?—Yes, I have heard it.

Do you really say that hearing the statement some time ago that it contained cocaine you have never taken the trouble to have the stuff analysed?—I do, emphatically.

Have you never taken the trouble to ask your brother *whether it did contain cocaine*?—I never did.

Is that because you were *anxious* not to know what it contained?—I have nothing to do with compounding it in any way or shape. My side of the business is simply commercial and my brother's is the medical.

To sell things which, if they contain cocaine, would bring you within the Pharmacy Act?

Mr. DUKE: It is a question of law as to the quantity; whether a *certain* element, cocaine or other ingredients, such as mentioned would bring a person selling a preparation of this kind within the authorities depends on the amount.

Mr. Justice RIDLEY: I discovered accidentally *that* a chemist who would supply you with a patent *medicine* without question a year ago would not supply it now without your signing a paper.

Mr. ELDON BANKES: *There* is no alteration in the Pharmacy Act.

Mr. Justice RIDLEY: But *there is* in the way it is administered.

Mr. ELDON BANKES: It is only because it has become known that some of these medicines contain these poisons.

Mr. Justice RIDLEY: The medicine I mean contains strychnine and it was known years ago—everyone knew it, Fellows's Syrup of Hypophosphites. People constantly buy it, and a most useful thing it is, I believe. It certainly contains strychnine. I was talking to a medical man about it the other day. Therefore, I thought people were more strict about it now.

Mr. DUKE: It very possibly is so; I do not know how that is. Of course, if the fact be that this gentleman must employ a chemist to sell *these* things, he must employ a chemist.

Mr. Justice RIDLEY: A chemist will not sell it to you now, seems to lodge in the nostrils and the back of the nose and create a slight irritation.

Have you tried a specific produced in competition with Tucker's in Tucker's atomiser?—I cannot say that I know the fluid was produced in competition with Tucker's, but I have tried a fluid which I have been told is supposed to relieve spasms of asthma.

You have tried other fluids?—I have tried another fluid.

In Tucker's atomiser?—Yes.

Did it have the effect?— As far as I can judge it had no effect whatever of any kind.

Did you get that fluid made up yourself?—No, I purchased it; it is a proprietary article.

Will you give me a description of it?

Mr. Eldon Bankes: I object to this.

Mr. Justice Ridley: I do not see that this is material.

Mr. Eldon Bankes: We cannot inquire whether other people are doing the same thing.

Mr. Justice Ridley: We shall get into protracted inquiry into all sorts of things.

Mr. Duke: I do not think so, my lord, for this reason: we have reason to suppose the ingredients are the ingredients my learned friend says are the ingredients of Tucker's.

Mr. Eldon Bankes: If they are they do the same wrong.

Mr. Duke: That is an observation which is hardly worthy of my learned friend's position.

Mr. Justice Ridley: That would make it material, because you have stated that the constituents of this medicine are so and so and so and so.

Mr. Eldon Bankes: Yes.

Mr. Justice Ridley: I really do not know what evidence you have on that subject, and I am speaking at random, but if Mr. Duke can show that a medicine made up of those ingredients has no effect at all I think that is material.

Mr. Eldon Bankes: My point about that is, it has the effect of poisons, and whoever sells the poisons without the proper safeguards we rightly or wrongly should say the same about them.

Mr. Duke: You would say it was fraudulent.

Mr. Justice Ridley: You have no right to say it is fraudulent; that is the difficulty in this case.

Mr. Eldon Bankes: That, of course, is the question we are trying here.

Mr. Justice Ridley: But you cannot.

Mr. Eldon Bankes: With great submission it cannot be relevant to this case to deal with the question of any other preparations.

Mr. Justice Ridley: No; I do not think it can merely as such, and I quite agree with you, but the difficulty I have is, if you have stated that certain ingredients are the ingredients of this stuff, and are deleterious, and he can show he has tried stuff made up of those ingredients and it has no effect at all, I do not see how it can be excluded.

Mr. Eldon Bankes: No one says that one single spray of this stuff would have any effect.

Mr. Justice Ridley: No, that is quite true.

Mr. Eldon Bankes: It is the constant use of it.

Mr. Justice Ridley: That is quite true. (To the witness) How often did you use this other medicine, once or more frequently?—I tried it for a somewhat prolonged period in order to see exactly, but probably a week or a fortnight—certainly not less than a week.

Mr. Duke: Did you give it a full trial with a view to seeing if it would relieve your asthma?—I did. Perhaps I ought to say it was owing to my not having at that time any severe attacks of asthma I thought I would take the opportunity of trying this other, but it did not relieve to any considerable extent the mild attacks that I did have.

Will you look at that. I do not propose to do other than identify it at the moment; is that the proprietary article which you used? (Same handed to the witness.)—It bears the same label.

You got it as that proprietary article?—I did.

Mr. Duke: I should like to have that identified.

Mr. Eldon Bankes: You can mark it. May I just look at it so that I may know what it is?

Mr. Duke: I can tell you what it is; it is Oppenheimer 21. Some question may arise about that. If your lordship would allow me I should like half of that taken from the bottle in order that I may be able to deal with it to test the suggested ingredients of it, and the other half to remain or be at the disposal of my learned friend. In order to be able to cross-examine I should have to be able to do so.

Mr. Justice Ridley: I do not see how I can object to your making the use you propose to make of it.

Mr. Duke: When it has been identified I should like to have half of it to see if it is correctly described to have the ingredients it has or not.

Mr. Justice Ridley: I do not know whether you will be able to do that. I expect Mr. Bankes will object to that.

Mr. Duke: I expect, if I am right in my hypothesis, to defeat his objection.

Cross-examined by Mr. Eldon Bankes.—I understand you tried some other atomiser and your objection to that one was that it did not make a sufficiently fine spray?—That is so.

Thomas Edward Mansfield, *examined by* Mr. F. E. Smith.—I think you are a member of the Bar?—Yes.

Have you been a sufferer from asthmatic trouble?—Yes, I have.

For how long?—It gradually increased up to two years ago for, I should think, the last 12 years. It gradually got worse up to two years ago.

Were your attacks severe or not?—Four years ago or three years ago they got very severe indeed. In fact, it got rather serious. Of course, I was using this before.

Were your attacks of a kind to interfere with your professional work?—Very much indeed; that was the serious part about it.

While you were suffering, and until you began to use Mr. Tucker's specific, as to which I will ask you in a moment, did you have medical advice for the treatment of your ailment?—Yes, certainly, and drugs too.

Taking it generally, you have tried many remedies, I think?—Yes; they were relief for the time but they were always objectionable.

Did the efficacy wear off with repeated use?—I had it daily and it was only a relief.

They returned as bad?—Yes.

Did your attacks come on in the night time?—Yes; they always come worse then; the moment you lie down, of course, it always begins.

What would be the duration of an ordinary attack?—Al night through if you have got asthma very bad. You may sleep for half-an-hour and then wake up again and want to breathe.

When did you first begin to use Dr. Tucker's specific?—I cannot fix the date, but it is a good many years ago. I bought the first instrument in Holborn personally. I was recommended.

Did you get it for trial first or not?—Yes; I had it a fortnight.

You did not part with your money for that time?—No; then I kept it.

Mr. Justice Ridley: You cannot tell me when it was?—I cannot.

Mr. Eldon Bankes: The plaintiff says that he moved seven years ago.

The Witness: I attended at the place personally in Holborn.

Mr. Smith: It is somewhere about seven years ago; that is sufficient?—Yes.

I want you to tell my lord and the jury what has been the effect of using this specific and atomiser upon your ailment?—I could not do without it. I can now comparatively, because in the atmosphere I am in—not just at the moment—it suits me better than North Lancashire.

You were formerly practising at the local Bar in Lancashire?—Yes.

Mr. Justice Ridley: But you can now?—I have it with me always by way of preventive, because I do not have it if I have it with me, but if I am without it I begin to think about it and begin to get asthma if you get nervous.

Mr. Smith: You always carry it with you?—Yes.

Have you got it with you now?—I have. Of course, it is nervousness, I suppose. If you know you have a thing that will give you instant relief and you have not got it with you and you have to do what our profession does, you get nervous for fear it should come on.

How long did you use it before you got into the condition in which you say you can do without it?—For the last 18 months I have used it very little.

You did not find the habit growing upon you?—I cannot understand anybody using it unless they want it; they are only too glad to be rid of it.

Mr. Justice Ridley: It is not pleasant to inhale vapour up one's nose, I must say.

Mr. Smith: Has it exercised that kind of seduction over

£18,498 17*s.* 10*d.* for the year 1907 up to a certain date. Can you now give me the date?

Mr. DUKE: Do you want it at the moment?

Mr. ELDON BANKES: I am finishing this point if you can give it to me.

Just look at that letter; that was the letter I was asking for; it is the Cushing letter. Is that letter issued from your so-called office? (Document handed to the witness.)—It is, and it has special instructions for the use.

Keep that in your hand; that is entirely printed?—Typewritten.

That would be sent out by one of the typists?—It is printed by the printers, but it is in a typewritten form.

It has been typewritten, but because you send out so many of them you have had it printed?—We send it with every trial that goes out.

Would that be sent out by the typist, for instance, without any communication with you at all?—Every single treatment that *goes out the typist puts in one of these.*

That is the one saying the treatment is absolutely harmless?—That is sent to every patient, or at least intended to be; if it is not it is *a mistake.*

Mr. DUKE: The figures Mr. Smith gave were for the whole year 1907.

Mr. ELDON BANKES: £18,498?

Mr. DUKE: That is under the heading of "Deposited," gross receipts, £19,678.

Mr. ELDON BANKES: I understand the gross figures for 1907 are £19,678, but they would exclude the agents' commission?—I think since May; that is my recollection.

Do you say now that this business, and a very lucrative business it seems to me, is worked upon the terms that you control Great Britain and the colonies and everywhere else except North America?—Practically so.

And your brother does North America?—Yes.

North America is not a very happy field for these enter*prises now, is it? How many States* to your knowledge have expressly forbidden the sale of your specific at all?—Not a single one.

Let me ask you this, Massachusetts?—We have, I think, more in the State of Massachusetts than any other State in proportion to the population.

Do you disregard the law there just in the same way as you do in England?

Mr. DUKE: I submit my learned friend is not entitled to make that statement.

Mr. Justice RIDLEY: I think he may make the statement; of course, we cannot take it as accurate.

Mr. ELDON BANKES: I will withdraw it.

Mr. Justice RIDLEY: I suppose under the Pharmacy Act the word "poisons" largely depends on what the quantity is?

Mr. DUKE: It does, and it has been a matter of judicial decision. The allegation is an allegation of fraudulent mode of dealing.

Mr. Justice RIDLEY: I must hear Mr. Bankes upon that, I think.

Mr. DUKE: I am not at all objecting that my friend is not entitled to investigate the matter fully, but the real question is whether the plaintiff conducts his business properly.

Mr. Justice RIDLEY: I thought that was what was alleged, but also it is alleged that there was the sale of poisons.

Mr. DUKE: But it only alleges that as a ground for saying that the plaintiff conducts his business *fraudulently.* Your lordship will see they say that the charges in the libel are fair comment because of various matters, and then it sums up with the statement, a late paragraph of the particulars, with the specific contents cocaine and atropine.

Mr. ELDON BANKES: I asked you about Massachusetts. Do you not know of the Statute of 1906 *in* the State of Massachusetts forbidding the sale of medicines containing cocaine, and directing *there shall* be no prosecution until the State Board of Health have publicly stated the *medicines* indicated; do you know that?—I know there was a law passed pertaining to that, but just what it was I do not know.

Do you know the newspaper called the *Boston Daily Advertiser*?—I know there is such a paper.

I ask you to look at *this advertisement* and see whether there is not here, in pursuance of the Statute——

Mr. DUKE: I must object at this point. If my learned friend has evidence of an unlawful act committed in the State of Massachusetts against the law of the State he must prove the law in proper order.

Mr. ELDON BANKES: I am prepared to prove the law. Mr. Barratt will come and prove the law.

Mr. DUKE: The question is this witness's knowledge. My friend produces a newspaper which, so far as appears, the witness has never seen and seeks to put that to the witness *as evidence of knowledge by him.*

Mr. Justice RIDLEY: I think he can do that.

Mr. ELDON BANKES: If he denies the knowledge I must prove it formally in the proper way. I am only asking him now whether of his own knowledge, in pursuance of the law, of which apparently he has some knowledge, he does not know that public advertisement has been made by the State Board of Health of the Commonwealth of Massachusetts including his particular medicine as one of those the sale of which is prohibited. I ask him simply, Did you know that?

The WITNESS: That it is prohibited?

Yes?—I do not know that it is. I know it is not, because the remedies are going in there every day in Massachusetts.

Have you had no correspondence with your brother on that subject?—I am not sure whether I learned it *from* him in a letter, or whether I learned it through a physician whom *I* met *from Brooklyn,* New York, but I heard something in reference to it.

Learned what?—That there was a law passed seeking to control the sale of *poisons or proprietary* medicines of all kinds without the *formula* being given in full.

Have you not since heard that your particular medicine has been specially excluded?—No; and had it been of course I should have heard of it.

Then I must prove it in the proper way. Do not you know that the same law prevails in the State of New Jersey? —I do not know anything about it.

Or any other State?—I know the *sale in the States* is simply immense: greater than mine here, much greater. My brother does more business than I do.

Mr. Justice RIDLEY: I suppose it will be *said against* you that that is the reason of the law being passed.

Mr. ELDON BANKES: Of course, that is my case.

Mr. DUKE: Your case is that he carries on his business fraudulently.

Mr. ELDON BANKES: Fraudulently, I know.

Mr. DUKE: Of course, it means nothing when you come into court.

Mr. Justice RIDLEY: As far as the libel is concerned I shall have to hear what Mr. Bankes says when it comes to a question of the meaning of it, but I certainly thought it was suggested that it was a fraudulent sale and it also *suggests that it is poisonous;* but I thought the main argument in the paragraph complained of was *against the Press* in assisting people to sell *remedies* on so large a scale by offering their columns *for* advertisements. We shall hear what Mr. Bankes says about it. He says it is not a remedy because it contains poisons in an improper quantity; and, secondly, it is fraudulent because the price is excessive.

Mr. ELDON BANKES: And because *it is sold* by a man with absolutely no qualification——

Mr. DUKE: That is not the allegation; there is no particular of that.

Mr. ELDON BANKES: Promiscuously, under, apparently, the Government ægis of the stamp; whereas really it ought to be labelled "Poison," and *sold* only under the restrictions applicable to things of that sort.

Mr. Justice RIDLEY: There is another point in the case which we shall have to deal with and *that is this,* that the coroner did not take it as being fraudulent, so far as I understand, except as being sold under the cover of the Government stamp.

Mr. ELDON BANKES: Your lordship will hear the coroner when he comes. Your lordship will see our amended statement put that right. We attacked it on both grounds.

SECOND DAY.

Mr. Justice RIDLEY: I wish to say that I observe in the *Times* this morning I am reported to have said that the proprietary medicine which I mentioned, Fellows's Syrup of Hypophosphites, had been marked as a poison. I never said it had *been* marked as a poison, and I am rather apprehensive that the remark might be *prejudicial* to the medicine, although I cannot quite say what it is. What I did say was, whereas you could buy it *freely* formerly in the chemists' shops, now if you go and ask for it you have to sign your name in the books. I do not wish to have anything reported from me which would be likely to have any prejudice on and I think you were formerly Mayor of Winchester?—That is right.

Mr. Justice RIDLEY: Winchester College, is not it?—Winchester School, commonly called Winchester College.

Has your form got a holiday?—We are all of us on holiday at present.

Mr. SMITH: Will you tell me, have you ever suffered from liability to asthma?—Yes; as a matter of fact I had a good many years ago an illness, indigestion it took the form of chiefly, and it gradually became more and more asthma. In 1903 I suffered more from asthma than from anything else, and called a doctor in for asthma.

I think you found it interfere a little with your work?—It interfered very greatly; I had frequent attacks of the two illnesses.

Did you take medical advice for it?—Yes; for asthma from 1903.

But without getting *complete relief*?—*Without* getting complete relief.

In what year was it that you first heard of Tucker's specific?—In 1904, in the summer.

Will you tell me what has been the effect upon your ailment of the use of Tucker's specific?—It has always given me *immediate relief*. When I have need to use it it still continues to give me instant relief. I think I use it rather less than I used to use it; in fact, I certainly do.

Have you found a craving growing upon you for its use, whether or not you have got an attack?—No, I have not.

Has the employment of it diminished the interruptions in your work to which you told us you were formerly subject?—Yes, I am quite sure of being able to get through a heavy time of work now because I expect an attack then and I always get relief from the use of it.

Mr. ELDON BANKES: I have no questions.

EDWARD SYMONS, *examined by* Mr. F. E. SMITH.—You are a member of the Bar?—I am.

You were subject for many years to severe attacks of asthma?—Ever since I was two years old, I am told. I have known it ever since I was four.

You have had it all through your recollection?—Yes.

In recent years have you become aware of Tucker's specific?—Yes.

Do you use it and keep it by you?—I am never without it. I have one of the atomisers at home and one at chambers.

What effect does it have if you have symptoms of possible attacks of asthma?—It gives immediate alleviation and relief, and very constantly so far as I know keeps it off altogether.

You mean you get symptoms which were formerly followed by an attack of asthma?—Yes, quite so.

And when you now use Tucker the attack does not come?—Yes.

Mr. Justice RIDLEY: It acts as a preventive?—Yes, it does.

As well as a remedy?—Yes, it does, most certainly.

Mr. SMITH: When did you get it?—I got it in 1900; it was 1899 or 1900; I am almost sure it was 1900.

In Holborn?—In Holborn; I went and saw Mr. Tucker himself.

By whom was it recommended to you?—It was recommended to me by one of the leading physicians in the West of England.

Do you know whether he was himself a user of it?—No, he was not.

So far as your experience goes is there any craving for this remedy if there is no ailment?—Absolutely not. I may perhaps say that I knew there was cocaine in it because a doctor friend of mine analysed it and told me so. He used it himself. He does not even go hunting without having it in his pocket, so I knew there was cocaine in it.

I hope your doctor friend who goes hunting has not become a victim of any cocaine habit, as it is called?—No, he has not.

Mr. Justice RIDLEY: He goes out hunting with it in his pocket?—Yes, he is never without it.

If he felt the symptoms in the middle of the run he would have some difficulty in using it?—I suppose he would wait till the hounds were called off. He is never without it.

Mr. SMITH: Something has been said about Mr. Tucker's honesty. Have you had any practical test of that?—Yes, I have: the bulbs of the atomiser occasionally wear out, so a few months ago I wrote to Mr. Tucker and asked him to send me three or four. He wrote back and said: "We will send them if you choose, but they deteriorate and wear out without use, and I would advise you not to have more than you want at the moment," and I was very much obliged to him, of course, and only got the one.

Cross-examined by Mr. ELDON BANKES.—I understand you to say that both you and your friend know that this contains cocaine?—I *do* not know it; I only know it from what he told me.

You believed him?—Absolutely.

Then you do know it in the ordinary sense?—Yes.

HIRAM DENTON, *examined by* Mr. SMITH.—I think you are a commercial traveller?—I have been.

You are retired now?—Yes.

Your centre of operations used to be Manchester?—I reside there.

Do you mind telling us how old you are?—61.

Have you had a constitutional liability to asthma?—Yes.

How long have you been liable to attacks of asthma?—30 years.

Did you find that the ailment was apt to interfere with your business?—Very much so.

I think you consulted doctors about it?—I did.

And tried a variety of remedies?—I have had an examination and was ordered out to Nauheim. My heart was weak with the remedies I had been taking, the different smoking mixtures and other things.

You were weak with these remedies and you were advised to go to Nauheim?—Yes, I was ordered to.

And you did go there?—By Dr. Dreschfeld, and I went to Nauheim, and whilst I was there I met a gentleman who recommended Tucker's atomiser.

Did you give us the date or not?—It was in 1901.

In 1901 I may take it you ordered a great number of remedies?—Everything I could hear of.

And consulted various people?—That is right.

Until 1901 had you derived any real or constant alleviation of your trouble?—Not any whatever.

When you got Dr. Tucker's atomiser did you, first of all, get it on trial?—I did.

And after trying you paid for it, and bought it, I think?—Immediately.

I want you to tell my lord and the jury what the effect of the specific as used in the atomiser has been with this long-standing complaint of yours?—It always relieves the attacks, but I am still subject to them.

In what state are you since you have used Mr. Tucker's specific as far as the power of alleviating your attacks is concerned?—Just the same as at first; still efficacious.

I was asking you for the moment to compare it with the time before you had Tucker's specific: do you follow what I mean?—No, I do not.

Supposing you have an attack, in regard to the alleviation of that attack are you better off with Tucker's specific than you were before you had Tucker's specific?—Yes, I am much better of course, very much better. I was going to die if I had not got that Tucker's atomiser.

You mean your attacks were so serious?—Yes, very bad.

May I take it your general health has improved while you have used it?—Altogether, yes.

You do not feel a craving to use it except when you are suffering from asthma?—Oh, dear no. I always have it in my pocket.

General CHARLES STEWART LANE, C.B., *examined by* Mr. DUKE.—You are a retired general in His Majesty's Army?—I am.

And a Companion of the Bath?—I am.

Did you more than 20 years ago become subject to recurrent attacks of asthma?—I had my first attack at Cashmere in 1884, and it nearly killed me.

Did you remain subject to severe attacks for many years?—I did.

Up to what period?

Mr. Justice RIDLEY: For how long did these severe attacks continue to recur?—For hours and hours—12 hours at a time, I may say, until 1894.

Mr. DUKE: Had you then come back from India some two years?—I came back in 1892.

In 1894 did you become aware of the Tucker specific?—I did.

Did you get it?—I got it sharp enough, yes.

What effect had it upon your asthma?—It took it away at once.

Have you had it by you from that time onwards?—I have it almost in every room in the house where I live. I do not know how many I have got. Yes, it is always with me.

physicians and others who would intimate to their friends that the fluid contains poison such as cocaine and is dangerous to use; they fail to take into account that you can throw the vapour with my Atomizer against a sheet of white paper without even staining it, which anyone can demonstrate who may have one of these instruments. This being the case you can readily see what an infinitesimally small amount of medicine is taken into the circulation." I ask you is not that written by somebody who is under a complete misapprehension?—It was written by Dr. Tucker himself.

Yes, I know; but is not the reason why no mark is made upon the paper that the spray is so fine that it does not condense, and it does not matter how long you go on spraying no mark would be made?—It would if you continue long enough; you could produce a slight discolouration.

I suggest to you that this is no test at all, and no indication?—That is a matter of opinion only.

But is not it an expression of opinion of a man who obviously is ignorant of the first principles of the effect of vapour?—The man who wrote that stands in his profession as high as any man in the State of Ohio.

Re-examined by Mr. DUKE.—Do you think you would like to charge him with fraud because he was mistaken when he wrote that, as my learned friend says he was?—Certainly not.

In your view he is not mistaken as I understand. In your view your brother is right about that?—Certainly, absolutely right.

I think I had better read this: "We are occasionally asked the question 'Will the continued use of the asthma remedy produce any injurious effects?' In reply we will say, once for all, that if used according to directions no perceptible effects whatever can be noticed. There is one thing that is not considered by physicians and others who would intimate to their friends that the fluid contains poison such as cocaine and is dangerous to use; they fail to take into account that you may throw the vapour with my Atomizer against a sheet of white paper without even staining it, which anyone can demonstrate who may have one of these instruments. This being the case you can readily see what an infinitesimally small amount of medicine is taken into the circulation. Also the medicine being applied directly to the seat of the disease only a very small quantity is required to produce the desired results. This statement being true makes this mode of treatment the *only one* that is entirely harmless. I make the assertion that this remedy can be used daily a lifetime with this Atomizer without any perceptible effects upon the constitution whatever if used according to instructions. The remedy has now been in use about 17 years. I have yet to learn that any bad effects have resulted in a single instance. This fact of itself should be sufficient to convince the most sceptical." This is a paper which you say your brother produced comparatively recently of which he sent you some copies?—Yes.

You have sent a few of them out?—I keep that and whenever a question comes up I inclose that in a letter instead of writing a long letter.

Apparently your brother writes on the assumption that there is some trace of cocaine in his *mixture*; he seems to assume that?—He takes the critic on his own ground, and he says: "If there is a poison." I think that is the idea he means to convey.

If used according to directions it cannot hurt?—That is so.

How long ago is it to your knowledge that your brother began using this remedy for his own asthma?—He had this remedy completed in its present form in the month of August, 1889, and he has been using it constantly ever since.

You say he is 70 years old?—Yes.

When did you see him last?—It is about a year ago last August.

What kind of physical condition was he in. Did he seem at all broken down by the use of cocaine?—He and I were travelling through the Rocky Mountains for seven months, and he was as good a climber as there was in the party.

That is when he was 68 or 69 you and he were on a climbing expedition in the Rocky Mountains?—Yes.

You yourself are 68?—Yes.

In the course of your business how much and how frequently do you use this preparation?—I use it for instance on Sundays, when I have no one to call upon me, four or five times during the 24 hours.

Are you subject to attacks of asthma?—I could not live here at all without this remedy.

You are naturally subject to attacks of asthma?—Yes, and our whole family are chronic asthmatics, but in my professional business——

Please do not hurry. That is on Sundays when you have your choice about how much you use?—Yes.

With regard to your chronic liability to asthma what has been your condition as to suffering from attacks of asthma during the time you have been living in London?—I can stand as much fatigue as almost any man of my age, I think.

Does asthma ever now take hold of you?—It would if I was to go out and run a foot-race of perhaps 50 yards; I should feel the effect.

But you do not run foot-races?—I do not feel it to any extent.

Going about in your ordinary habits as a man of 69, does asthma take hold of you now?—Not to any extent at all. It would be a slight coughing or irritation of the bronchial tubes, but no asthma.

That is the manner in which you use it, because of your liability to asthma?—Yes.

With regard to your other user do you demonstrate to persons who are seeking to buy this apparatus the use of it?—There is never a day but what I demonstrate it to some of those who are calling at the office. Some days I have a continual string of callers all day long, and I am constantly using it all day long showing people how to use it. I never hesitate a moment about doing it. I have been doing so for 17 years.

You did it while you were assisting your brother in his dealings with the specific in North America?—Yes.

And you have been doing that ever since you came to England?—Yes; more so since I came here.

Has that been increasing since the business increased here?—The climate here is harder on an asthmatic than it is in the States.

So far as your experience is concerned, is there any ground whatever for the suggestion that the use of this specific affects the *general health of the* patient?—Quite the reverse. It improves the health, because he can breathe properly; it does *not* affect the health one way or the other directly, but indirectly it affects the health because he can breathe.

It is suggested that the use of the specific poisons the system of the patient?—I do not look as if I have been badly poisoned, do I?

Mr. Justice RIDLEY: That is for the jury.

Mr. DUKE: With regard to your atomisers, have you had customers who have been customers ever since you began?—I have.

And who remain customers now?—Yes.

You see them from time to time?—Many of them I see quite often.

Is there one of your customers who shows any kind of symptoms that my learned friend has referred to of being a poisoned person?—Not one.

Have you ever heard either from your patients or the relatives of your patients any suggestion of that kind?—Nothing of the kind.

Did you ever hear it at all from any person who was practically concerned in the use *of this remedy*—who was using this remedy?—No, I never heard it at all—nothing of the kind.

My learned friend asked you about the *Oppenheimer* atomiser. Messrs. Oppenheimer are people in a large way in the drug trade in the supplying of the matters which doctors and chemists use for the cure of ailments?—I understand so, yes.

Mr. ELDON BANKES: I must object to this. I did not put in Oppenheimer's atomiser. Tucker produced it in the box.

Mr. DUKE: I thought my learned friend produced it.

Mr. Justice RIDLEY: No; he said it was the only one he had come across that would produce vapour and not spray.

Mr. DUKE: I thought my learned friend had produced it.

Mr. Justice RIDLEY: Mr. Bankes put a question about it just now.

Mr. ELDON BANKES: But only as to its strength and how it acted as compared with his.

Mr. DUKE: Well I will not raise any controversy about it.

There are undoubtedly a great many of these atomisers?—The world is full of them.

Do you find that there are preparations being advertised to compete with your brother's preparation?—Lots of them; they have been at it for years.

Do you find among your patients that they become aware of it?—Yes.

of asthma from about 30 years ago. In the later years the attacks increased in severity, in frequency, and in duration.

To what extent had that affected your ability to follow your profession?—It prevented me attending business regularly, and I had to leave business very often suddenly.

Since you have had the Tucker specific and used it, what has been your condition as to asthma?—I have been practically independent of and free from asthma. I do not mean actually free from it, but the attacks of asthma can always be controlled, and they never interfere with my arrangements in any way.

With regard to this suggested craving for the preparation do you find any craving for it?—Not the slightest. I do not use the specific as often as I should do. I could use it between attacks so as to prevent attacks, but I only use it when the attacks are actually imminent.

With regard to your general health, how has it affected your general health?—My general health is much improved. My health is normal now; I can eat, drink, and sleep.

Dr. THOMAS CLARK, *examined by* Mr. DUKE.—You are a registered medical practitioner?—I am.

Where do you carry on your practice?—Wandsworth Common.

Have you been subject to asthmatic attacks?—I have.

Did you become aware of Tucker's specific some years ago?—Eight years ago.

Did you adopt the use of it?—I did.

What was the effect of it?—I have been kept from my work for three months on account of it.

On account of what?—On account of the asthma.

I am speaking of the specific. What has been the effect of the use of the specific since you have had the specific?—The effect of it is instant relief.

Since that time when you adopted the use of it eight years ago have you continued to use it?—I have.

Have you found the same benefits?—Always.

I do not know whether you know the composition of it yourself or not?—I do not.

Do you find in your case anything of the nature of a craving for the specific when you were not in danger of an attack of asthma?—Not the slightest.

It is fair to you to say that you did not see your way to give Mr. Tucker a proof of any evidence?—I did not.

You are attending here on subpœna?—Exactly.

Cross-examined by Mr. ELDON BANKES.—As a medical man perhaps you can tell me something about cocaine. Are you familiar with the effects of cocaine?—We use it in practice, certainly.

First of all, is it a poison?—Yes.

And a poison which appears under the schedule to the Pharmacy Act?—I believe it does.

Mr. Justice RIDLEY: It is not in my copy as far as I can remember.

Mr. ELDON BANKES: Your lordship will remember that the Act provides that in addition to the poisons appearing in the printed schedule additions may be made from time to time by the Privy Council by Order.

Mr. Justice RIDLEY: It has been added afterwards?

Mr. ELDON BANKES: Yes.

Mr. Justice RIDLEY: No doubt it would be classed amongst poisons.

Mr. ELDON BANKES: Coming under the schedule to the Pharmacy Act do you know that the sale of it is surrounded by certain restrictions?—I have no means of judging that. We buy it from the wholesale drug houses in the usual way with other drugs, of course. A layman would be the one to give that evidence.

You do not know, perhaps, the provisions of the Pharmacy Act concerning the sale of poisons?—I know they have to sign a book when they receive it, but that does not apply us.

The Pharmacy Act does not apply to a prescription by a duly qualified medical man?—No.

I want to know a little about cocaine. Of recent years have doctors found that cocaine ought only to be used under very stringent precautions?—When injected under the skin it has to be used with great precautions.

Has it been found that some persons are extraordinarily susceptible to cocaine?—Yes, when used in the manner I have indicated.

We will come to the use in a moment. Has it been found that in some persons it will produce the most dangerous symptoms although administered in minute quantities?—All I know is when injected under the skin.

You are confining your remarks at the present moment to when injected under the skin?—Exactly.

Has it been found in some persons when injected under the skin in minute quantities it produces the most dangerous symptoms?—Exactly.

Do you know that some doctors now, many doctors, refuse to prescribe cocaine at all?—I was not aware of that.

Do you know that many doctors, when cocaine is prescribed, indicate on their prescriptions that it is not to be made up again without a further order?—No, I do not.

May I ask, do you hold any qualification, and what is your qualification?—I am a Licentiate of the Royal College of Physicians of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow.

Is yours a general practice at Wandsworth Common?—Mine is a large general practice at Wandsworth Common.

You have spoken of the effect of cocaine if administered by injection?—I have.

Of course, if administered by injection it is quickly absorbed into the system?—Instantaneously, of course.

Have you considered whether a drug would be readily absorbed into the blood if inhaled?—Yes, it would be absorbed into the blood, I have no doubt.

And more readily absorbed into the blood if inhaled than if swallowed?—I should say so.

In addition to this peculiarity of cocaine, that many persons are extremely susceptible to cocaine, is it within your knowledge that very small quantities of it produce the cocaine habit in patients?—I have never met with a case.

Have you never had a patient with the cocaine habit?—Never.

Do you know from your medical reading that the cocaine habit is very readily acquired by certain persons?—I do.

Of course, it depends upon the state of health of the patient and his susceptibility as to whether he or she will acquire it or not?—I do not think so.

For instance, some persons would be more apt to acquire the cocaine habit than others?—Yes, some are more weak-minded.

And many people might take a quantity of cocaine without the habit, whereas the same quantity might produce it in another person?—Certainly, that might be so with anything.

Do you know that the cocaine habit is more difficult to deal with and cure than either the alcoholic habit or the morphine habit?—I have no experience of it.

Is that the result of your reading about the cocaine habit?—I have no experience of it.

Either by reading or otherwise?

Mr. Justice RIDLEY: I have never met anybody with it.

Mr. ELDON BANKES: I am glad your lordship has not.

Mr. Justice RIDLEY: Have you? Let us see what we are dealing with. The alcoholic habit, I am sorry to say, is very familiar to us all, but I have never met anyone with the cocaine habit.

Mr. ELDON BANKES: The cocaine habit is not so prevalent. You can only buy cocaine under stringent restrictions unless you get it through Mr. Tucker. Of course, alcoholism is very common and the cocaine habit is not so common.

Mr. Justice RIDLEY: That is what I say. Surely it must be infrequent. I thought it was chiefly to be found amongst the Indians of South America.

Mr. ELDON BANKES: Because, of course, coca is obtained there from which cocaine comes, but I think your lordship will hear it is unhappily prevalent in this country.

Mr. Justice RIDLEY: I suppose it is from what you say.

Mr. DUKE: There is no suggestion of it in the pleadings and there is no issue of it in this case, and at some time or other I shall have to ask your lordship's ruling as to whether my friend can deal with it.

Mr. Justice RIDLEY: We must get our facts first.

Mr. ELDON BANKES (to the witness): Is cocaine a drug which it is extremely unwise to administer to a person who has got a weak heart?—I should say that it depended on the dose that was given.

But speaking generally is it unwise to administer cocaine to a person suffering from a weak heart?—I should use it in certain cases whether they had a weak heart or not, quite indiscriminately.

Of course, you would require to examine the patient very carefully before you would administer cocaine at all?—Certainly not.

And of course he has no carriage. He does not have the item of expense that you have, being resident in this country?—Nothing like it. His net profit is much larger than mine.

Your books have been referred to. Have you worked out, as far as you were able to, what your net profit is—what your percentage of profit is?—As near as I can estimate—it is an estimate because I have not kept an accurate account of the expenses—the net is about one-third of the gross receipts.

Mr. Justice RIDLEY: Net profits do you mean?—Yes, one-third of the gross receipts; that is 33⅓ per cent.

Mr. ELDON BANKES: That is quite new.

Mr. DUKE: It follows entirely on what my learned friend has been cross-examining on.

Mr. Justice RIDLEY: It follows, of course.

Mr. ELDON BANKES: It does not appear in the books.

Mr. Justice RIDLEY: No, he would not have taken it out in the books, I suppose, so it would not appear.

Mr. ELDON BANKES: Of course, it would appear in the books if he chose to keep a full account of the expenses.

Mr. Justice RIDLEY: If you chose to put them together it would.

Mr. ELDON BANKES: Of course, if all the materials are there you could find out, but the materials are not all there.

Mr. DUKE: If my learned friend wants to ask a question I am not going to raise any objection in a case of this kind.

Mr. ELDON BANKES: Will you ask him to give us all the items of expenditure?

Mr. DUKE: I will ask anything my friend wants to ask, but if my friend wants to cross-examine further——

Mr. ELDON BANKES: I should prefer it.

Mr. DUKE: Very well.

That is your estimate, one-third?—Yes.

With regard to the volume of that business has the volume of it been obtained in the manner and been the result of efforts which you have explained to the jury?—Yes.

And of the success of the specific?—Yes.

Further cross-examined by Mr. ELDON BANKES.—With regard to these profits there are no materials in your books enabling anybody to ascertain exactly what your net profit is?—There has never been any accurate account of expenses until about the 14th of last May; from that date we have an accurate account of expenses.

Did you give us yesterday all your items of expeditures?—No, I was not asked for them; I gave all that were asked for.

Let me understand. There is your house rent, of course?—Yes.

You live in the house?—Yes.

Do you debit your business with the whole house rent and rates and taxes and so forth in the estimate of 33 per cent?—I have debited the business with one-fourth of the amount and one-fourth of the expense of keeping up the house.

Is that in your estimate of 33 per cent.? I understand you have been keeping accounts since May and now you may have kept them properly, but when you speak of your rough estimate of your net profits being 33 per cent., are you taking into account that you debit the business with the whole rent of the house?—Never, no.

Then I understand there are the wages of the six people who are employed in the house?—Yes.

There is the commission for the agents?—Yes.

There is the cost of the materials?—Yes.

The atomisers and so forth?—Yes.

And there is the item of carriage?—Yes.

Is there any other item of expenditure?—There is the item of stamps: postages and medicine stamps.

Revenue stamps. Is there any other item?—It would all be included under the supplies.

Of course, the cost of the materials and so forth?—Yes.

Your learned counsel suggested yesterday it would be right to deduct your income tax before arriving at your net profit. Have you done that?—I did not.

So that we know the items of disbursements although they do not appear in full in the books?—No, I have not kept an account of expenses.

I asked you yesterday and you told me you thought it was approximately correct that your gross receipts for the year 1906 were £19,800, I think, and that the amount you paid your brother for the liquid and the parts of the atomiser that he supplied was £5,600?—I do not know what the amount I paid him was. The books would show that exactly; you can get it to a fraction, but I have not footed it up.

Further re-examined by Mr. DUKE.—You tell us your estimate is one-third net profit?—Yes.

Is that an estimate worked out in detail in figures, or a rough estimate?—It is worked out in detail as accurately as we could do it without keeping an accurate account of every item of expense.

Have you got it worked out?—No, I have not got it here. I worked it out with one of the Revenue inspectors four years ago.

You had to deal with one of the Revenue inspectors with reference to your income?—Yes.

Then you made it out?—We made it out together.

That is how you got at your one-third?—Yes.

EDWARD ALFRED COOMBS, *examined by* Mr. DUKE.—You are the Borough Treasurer of the Borough of Kensington?—That is so.

You are 41 years of age, I think?—42 now.

Had you for many years formerly been subject to attacks of asthma?—I had.

Since about what time?—I cannot fix the exact date, but certainly upwards of 13 years, probably 15.

Have they been severe attacks?—Very severe until recently.

Had you undergone treatment for them?—Yes.

And used a variety of remedies?—Yes, many.

Have you been successful or not?—I found that some of the remedies were more or less successful for a time, but after a time they lost their effect entirely. I might say after a short time, after a few months, they lost their effect.

Since what period have you ceased to be subject to frequent severe attacks of asthma?—Within the last two years.

Is there anything which fixes the point of time?—Yes.

What is it?—I obtained from Mr. Tucker on the 2nd or 3rd of February, 1906, one of his atomisers on 14 days' free trial, and there was a gradual improvement from that time, which has resulted in an almost complete cessation of severe attacks of the asthma.

Has the specific continued to have a beneficial effect, if you have to resort to it, or not?—Most decidedly.

It has been suggested that the use of the specific has some effect on the general health. What has been your condition as to general health since you have been using the specific?—My health has been much better—considerably better since I have used the specific. If I may add something to that, formerly I was very susceptible to taking ordinary colds, and they were invariably followed by severe attacks of bronchial asthma which confined me to my bed for anything from a week to a fortnight, but since that time I have managed to disperse colds in a few days without taking to my bed except on one occasion. I also find that whereas formerly I had to be very careful in my diet I can now eat and drink what I fancy without any ill-effect.

With regard to the use of the specific were you formerly much subject to disturbance by asthma in the night?—Almost every night up to that time since I first had an attack of asthma I was obliged to leave my bed to inhale something from some burning powder, or use some other remedy of that kind occasionally two or three times in the night. I think I may say always once at least.

What has been the effect of the use of the specific in your case with regard to that liability?—I think that since using the specific on no occasion have I had to leave my bed to relieve an attack. The plan I follow is to keep the atomiser quite handy at the side of the bed, and should I be awakened in the night I just use it for possibly a minute, but I fall asleep again and know no more about it.

With regard to the use of the atomiser, can you give us any idea, in order to deal with the question of quantity, how many compressions of the bulb are required to give you the dose of vapour which you want for your purpose?—I cannot tell you what the minimum number is that would produce the result, because I am never at all careful. I use it just as I feel inclined to use it at the time, but I may say when I first began to use this my breath was so bad that I could not inhale more than three compressions of the vapour up each nostril at a time. I can now with ease do from 10 to 15 in one breath, and I never take less than 10, I suppose.

And you find it perfectly successful?—Perfectly.

Have you tried the use of Tucker's fluid in other atomisers or another atomiser?—I did on one occasion try the use of Tucker's fluid in another atomiser but I found it did not break it up sufficiently finely.

When it is not broken up sufficiently finely does it have a beneficial result?—No, it has rather a deleterious effect. It real risk of her falling into pernicious habits by her inhaling this vapour?—No, I did not.

Cross-examined by MR. ELDON BANKES.—I understand that you suggested this for one of your own patients?—Yes.

Would it, under those circumstances, be used under your own supervision?—I was not there, of course, when she was using it.

She continues to be your patient?—Yes, certainly.

So that if you observed any ill effects from it in her case, you would be able to stop it?—Certainly.

Cocaine is prescribed, is it not, by doctors for certain purposes?—Yes.

Is it in your opinion a very potent and dangerous drug?—It is very potent, certainly, and very dangerous by improper use.

In your opinion ought it ever to be used except under the most careful precautions?—No.

Do you think it legitimate to supply people with a specific containing cocaine without having ascertained exactly what it was from which they were suffering before it was delivered?—I should not do so, certainly.

Do you know that the symptoms of asthma are very often confused by patients with the symptoms arising from heart disease or from phthisis?—Yes.

So that a patient may think he is suffering from asthma and say so, although he is really suffering from heart disease or phthisis?—Certainly.

Is cocaine a drug which it is proper to administer in cases of heart disease or phthisis except after careful examination, and under supervision?—I should not administer it at all except under careful supervision, of course.

Is cocaine a drug to which certain persons are extremely susceptible?—Certainly.

Even administered in very small quantities has it been known to produce most dangerous symptoms?—Yes.

In your opinion is that result confined to cases where it is injected under the skin?—No, it is not.

Has it been known that the same result applies where it has been rubbed on people's gums?—Yes.

And in whatever form it is applied to people has it produced this extremely dangerous result?—That is rather sweeping, but certainly in more ways than one. I do not think it makes the least difference how it is applied as long as it is absorbed.

Do you agree that cocaine, or any similar drug, would be more readily absorbed into the blood if inhaled than if swallowed?—That would depend upon the condition of the stomach entirely. It would be absorbed very readily from an empty stomach, but not from a full one. I should say, applied as vapour to the lung, it would be absorbed as rapidly as it would be from an empty stomach—more rapidly than it would be from a full stomach.

Do you think it is safe to sell a specific containing a considerable quantity of cocaine indiscriminately?—Speaking generally, certainly not.

Are you familiar with the cocaine habit?—I have seen it.

Do you, from your reading, know that it is very easily acquired by certain persons?—Yes.

And if acquired it is one of the most difficult habits to eradicate?—Yes, it is.

And has the most dangerous results of any?—I do not say that quite, but I should put it rather on a par with morphia.

MR. JUSTICE RIDLEY: Opium?—Morphia is the active principle of opium.

MR. JUSTICE RIDLEY: I know.

MR. ELDON BANKES: I ought to ask you about this. Is atropine also one of the poisons which is scheduled to the Pharmacy Act?—Yes.

And are the effects of atropine somewhat similar to those of cocaine, but not so dangerous?—No, I should say they are quite different. One does not see chronic atropine poisoning. If anyone sees atropine poisoning, it is acute; a person has taken a single large dose of belladonna generally. It is not quite the same kind of thing.

MR. JUSTICE RIDLEY: Is atropine the same thing as belladonna?—It is the active principle of belladonna.

Re-examined by MR. SMITH.—I will not follow into the general question at all, but with regard to the patient to whom you recommend the use of this specific, she took a fortnight, I think you told us, to try it?—Yes.

During the fortnight that she tried it, did you think it necessary to be present on any one occasion when she was making a trial of it?—I could not very well because it was almost always in the night.

You did not, as a fact; I will not follow you into the reason?—No.

So far as your patient was concerned she was permitted to form her own unassisted judgment as to whether or not it would be beneficial or injurious to her?—Yes.

You saw neither danger, inconvenience, nor impropriety in allowing your patient to do so?—No, I did not.

MR. JUSTICE RIDLEY: Will you tell me one thing. We are told it would take something like six months to consume an ounce of this mixture—of this specific?—Yes.

And we are told that 1/300th part of it is cocaine?—Yes.

Do you think the consumption of 1/300th part of an ounce of cocaine in six months would be likely to be prejudicial to anybody?—I certainly cannot say it would not be to susceptible persons.

1/300th part of an ounce in six months. Do you mind telling me what that is in grains?—That is all the cocaine there is in this mixture.

How much is the quantity of cocaine?—1/300th part is cocaine. It is about one grain, is it not?

1/300th part of the ounce is cocaine—1½ ounces?—Yes.

In six months?—I should not expect it to be with most people.

MR. SMITH: And that is assuming, of course, my lord, that it is all absorbed into the system?

MR. JUSTICE RIDLEY: That is all there is in the ounce.

MR. SMITH: It is all that can be absorbed by the most retentive constitution?

MR. JUSTICE RIDLEY: Yes, if you take it all into you, it would be one grain and a half in six months.

MR. ELDON BANKES: Your lordship says six months. That, of course, is assuming that that particular patient took six months.

MR. JUSTICE RIDLEY: I am only taking the average; it is quite true.

MR. ELDON BANKES: Of course, if the patient took six months to take it he would take very small quantities, but there is no reason why the patient should not take it all in a week.

MR. JUSTICE RIDLEY: We were told how long it would take.

MR. SMITH: Of course, if you chose, you could take it all in a week?

MR. ELDON BANKES: Directly you got the cocaine habit you would take an ounce in a week, or something like that.

MR. SMITH: I think Mr. Bateson told us that he took it frequently?

MR. ELDON BANKES: Very likely he took it frequently, but not an ounce a week.

MR. SMITH: I do not know whether my friend is going to call witnesses who took an ounce in a week. On that point, as it may be of importance, will your lordship allow me to recall Mr. Symonds, who, as your lordship knows, is a member of the Bar, and he will tell us the time an ounce lasts?

MR. JUSTICE RIDLEY: If you wish to do so, I do not see any objection to it. I have only got the average, and I am not quite sure it is quite right, because I am not quite sure, to tell you the truth, whether Mr. Tucker said it was five months or six months.

MR. SMITH: The evidence has varied.

MR. ELDON BANKES: In the pamphlet Mr. Tucker says it will last two to three months.

MR. SMITH: Four months.

MR. ELDON BANKES: Whatever the figure is.

MR. EDWARD SYMONDS *recalled*.—MR. JUSTICE RIDLEY: How long did an ounce last you?—An ounce lasts me from 12 to 18 months; I think always over twelve months, and nearer 18 months.

MR. SMITH: Is the explanation of the time that an ounce lasts you that you make infrequent use of it?—I use it constantly. I may use it—I cannot tie myself literally to every time—from eight to ten times in an hour, almost through the 24 hours. I use it constantly.

You were a very severe sufferer indeed, I think, at one time?—I got sometimes almost unconscious from it. I have the most horrible attacks of asthma—I used to.

Further cross-examined by MR. BANKES: You say you used it very constantly occasionally. That would be, I assume, when the attack comes on?—No; I have used it constantly when there is no attack, if I had had any sort of fear that there might be going to be an attack, if I thought I might have got a little chill, or anything of the kind.

For instance, does a fortnight or a month sometimes you that you are not happy unless you are using it?—No, it has not indeed.

Would you say, in fact, your use of it has grown less?—I never use it unless I need it, and as I say I cannot understand anybody using it for amusement.

Whenever you have a spasm does it in fact give you relief?—Immediately.

Cross-examined by Mr. BANKES.—I understand that you have arrived at the happy state when it is just as much use in your pocket as in your nose?—It is certainly very much better in my pocket than in my nose.

Re-examined by Mr. DUKE.—I daresay it suits both your comfort and your pocket to have the atomiser there than being kept going day and night?—Yes, the only thing that rather bothers me is that it costs 1*s.* 6*d.*, and I have to pay 8*s.*

Mr. Justice RIDLEY: But now you have got past that.

Mrs. FANNY STEWART, *examined by* Mr. DUKE.—Are you the wife of Major General Robert Stewart?—Yes.

Do you live at Hove with your husband?—Yes.

Your husband, I think, is a very aged man?—Yes; he will be 83 in two months.

He is not able to leave home now?—No; not in this weather.

Was your husband for many years subject to severe attacks of asthma?—Only for the last four or five years.

During that time, was he under medical treatment frequently?—Nearly always.

Did he become a purchaser of Dr. Tucker's specific?—Yes; two years ago last November.

He had it on trial, I think?—Yes; he heard of it by accident, but he was very, very ill at the time.

Was he ill with asthma at the time?—Yes; asthma and bronchial catarrh, which caused incessant coughing. The asthma began to affect his heart. The doctor thought very seriously in his case.

You say he had it on trial, but what was the effect upon him of the use of the specific with the atomiser?—He had relief at once. Within 24 hours he was quite in a different state, and if I remember rightly he used it first on November 3rd, 1905, and he wrote within a week that he would purchase it.

And pay for it?—And pay for it, certainly.

You have told us what his condition had been up to that time during the previous two or three years. What has been his condition since that time?—He has gradually grown much stronger.

With regard to the recurrence of attacks of asthma, has he had attacks such as he had before he used the specific or not?—Not nearly so often, and it also affects the coughing very much. The asthma was caused in his case by the incessant bronchial coughing.

Do you find in his case that the specific continues to afford him now the relief that it afforded him two years ago?—Yes, quite the same; it has never failed.

Of course you personally have no interest in Mr. Tucker's success or failure?—No; I never heard of the specific, and I never heard of Mr. Tucker until one of the tradesmen came up to the house——

Mr. ELDON BANKES: Well, we cannot have that. I have no questions.

ARTHUR BELFIELD, *examined by* Mr. DUKE.—You are by profession a solicitor?—I am.

Do you live at 7, Kensington Square Mansions?—Yes.

Are you 50 years old?—I am.

Were you for very many years subject to severe attacks of asthma?—I was.

For how long?—For about 30 years I have been.

Had it any effect with regard to your profession?—Yes; it had a very serious effect. I was compelled to leave my business in the country and to come to London in consequence.

Did you remain subject to asthma after you came to London?—I did.

During a great part of those 30 years were you using a great variety of inhalations and remedies of one kind and another?—I was.

Under medical advice or not?—No.

Were you treated by doctors for your asthma?—I was.

By few or many?—I should think by eight or nine.

When did you first get any relief from the recurrence of these severe attacks of asthma?—That is a question that I really can hardly answer. The attacks were always with me more or less, and I got temporary relief from various inhalations.

Did you some years ago become aware of what is called Tucker's remedy—the remedy sold by Mr. Tucker, the plaintiff?—I did.

Do you remember when that was?—Yes; it was either in March or April, 1900.

Did you get it?—I went to see Mr. Tucker.

Mr. Justice RIDLEY: In Holborn?—In Holborn, yes.

Mr. DUKE: Did you get the remedy—the apparatus and the liquid?—I had it on trial first for a fortnight.

At the end of the fortnight did you purchase it?—I bought it, yes.

What was the effect of the use of the vaporiser and the fluid?—It afforded me the most marvellous relief.

What has been the subsequent effect with regard to your general state of health and with regard to your liability to asthma?—The remedy has continued to give me the same, or almost the same, relief as it did on first using and my general health has improved immensely by the relief from the strain of the attacks.

Can you give me an instance with regard to the effect of localities upon you and the consequence of using the remedy?—Yes; there are some places the air of which brings on attacks with great violence, and in which I have found that the relief obtainable from Tucker's remedy is very much reduced, but these places are quite exceptional and of course I avoid them.

But without the remedy would you be able to venture into those places at all?—No; I should be very sorry to.

Mr. Justice RIDLEY: Tell me one or two of them?—There is a place on the Quantock Hills near Bridgewater that have had entirely to give up visiting—a friend's house. Bournemouth is another place.

Mr. DUKE: Do you mean that if you have the protection of the specific you can venture into those places, but if you have not you cannot?—I should be very sorry to go, even with it. I may add that I have used the remedy sometimes for several hours, I do not mean without stopping, but several hours during one night to keep me going. I could not have got through the night without it; but still I was pretty miserable with it.

You told me what your condition of general health has been. Will you tell me whether you have observed any tendency following the use of the specific to want to use it although you had not any asthma?—Certainly not.

It is suggested it exercises some sort of seductive influence on the person who uses it so that he will not be able to get on without it whether he has asthma or not. Is there any foundation for that in your experience?—Certainly not.

I think you have not only used this yourself. Have you provided it for other persons?—I have provided it for sundry poor people who were unable to pay for it, and have had it at reduced prices.

You have bought it at a reduced price because you were giving it away?—Mr. Tucker let me have it for £2 in those cases instead of £3.

Mr. ELDON BANKES: I have no questions.

Mr. Justice RIDLEY: How many witnesses are you going to call, Mr. Duke?

Mr. DUKE: If my friend does not challenge this evidence I do not want to call a lot of witnesses, but it is a serious question and I would like to call one or two to represent a somewhat different class.

Mr. ELDON BANKES: I am quite prepared to accept any number my friend will give me that he has got here of witnesses who will give the same kind of evidence as this witness. I do not dispute that this drug may give relief, and in many cases with beneficial result. I am quite prepared to take my statement in this general way; if my friend will give me the number I will admit that they will give similar evidence.

Mr. DUKE: I have a very large number of persons.

Mr. ELDON BANKES: Will you tell me the number you have here?

Mr. DUKE: I will call one or two, and if my friend does not cross-examine I will leave it there.

Mr. ELDON BANKES: I should not cross-examine if they give the same kind of evidence.

Mr. DUKE: Very well, I will call one or two.

JAMES ALFRED FORT, *examined by* Mr. F. E. SMITH.—I think you are an assistant master at Winchester School, said death resulted from old standing and advanced consumption. The deceased used a spray which cost £3 3s., and a fluid that cost 8s. an ounce. The Coroner: 'Some quack remedy.' The widow stated that the deceased thought the use of the spray and liquid relieved him. The Coroner: 'Do you think it hastened his death?' Dr. Paton: 'I can't say that it hastened his death. Many of these things are quite ineffective, and, therefore, harmless.' The Coroner referred to the advantage that quack remedies had among the poor and the ignorant because they bore the Government stamp. Many people, he said, took the stamp to mean that the quack remedies were guaranteed by the Government, whereas many of them contained noxious drugs that might cause a great deal of mischief."

You heard all the coroner said. I want to ask you whether the coroner said either that Tucker's dealing was a fraud, or that the remedy was a fraud?—I do not remember it.

If he had said it do you think you would have remembered it?—I think I should have included it in the report.

Would it have been good copy?—I think so; yes, very good.

As far as your memory goes your summary of what took place was accurate?—Yes.

Cross-examined by Mr. ELDON BANKES: I understand you have no note at all of what took place?—No, no note.

When were you first asked what you recollected?—Perhaps three months ago.

Two months ago?—Two or three.

This inquest took place in January, 1907?—Yes.

And you were asked, we will say, in October or November, 1907?—Nine or ten months afterwards.

Was there anything special to cause you to retain the events of this inquest in your mind?—No, nothing particular.

I suppose in order to refresh your memory you looked at your newspaper?—Yes.

You do not find in your newspaper any reference to the word "fraud" at all, do you?—No.

Have you looked at any other newspaper reports?—I have glanced at the *Morning Advertiser*.

It is quite plain that the *Morning Advertiser* uses the word "fraud"—I will not say in what connection?—Yes.

Have you any doubt that the word fraud was used by the coroner?—I am almost certain it was.

So that your recollection now is that the coroner did use the word fraud?—Yes.

You did not include that in your report at all?—No.

I think you misunderstood my learned friend a moment ago when you said that if he had used the word you would have put it in?

Mr. SMITH: No, he did not say that. What he said was if he had used it either of Tucker's dealing, or Tucker's medicine, he would have put it in.

Mr. ELDON BANKES: I see. You think he did use the word "fraud"?—Yes.

Have you any distinct recollection of the connection in which he used the word?—Yes, my recollection is that he used the word "fraud" in connection with the putting of the Government stamp upon patent medicines.

That is your recollection?—Yes, distinctly.

You say that without any note to remind you?—Yes. I feel now that had he said that this particular remedy was a fraud, I should have used the word, and used the phrase.

You are arguing now as to what you would have done if something had happened?—Yes.

But you have no distinct recollection?—No distinct recollection.

I suggest to you that the coroner used the works "quack" and "fraud" with reference to Dr. Tucker and his treatment; but your recollection is not that?—Knowing Dr. Waldo——

That is another argument?—That is another argument, as you say.

Dr. Waldo is a person in whom you place reliance?—Yes.

If he comes and says he did you would not dispute it?—It is a question of memory, I think, in both cases.

Mr. ELDON BANKES: That is quite a fair answer.

Re-examined by Mr. SMITH.—Just to be quite clear, with regard to a well-known medicine like this, you think it would have been good copy if it had been described as a fraud?—Yes.

Perhaps you do not think it would have been equally good copy if the Government system of putting stamps on is called a fraud. Is that equally good copy?—I thought I covered that point without making use of the word fraud. I might or might not have used the word fraud, but I thought I covered the point.

But in the other case it would have been a thing which would have struck you?—Certainly.

As to whether your memory was only refreshed by your own report, when you were shown your own report, were you also shown the competing reports—the other reports?—I believe so at the same time.

Your memory was refreshed impartially by both?—Yes.

Mr. SMITH: That is the plaintiff's case.

Mr. ELDON BANKES: May it please your lordship, gentlemen of the jury: In this case I appear with my learned friend, Mr. Fraser, for the newspaper, THE LANCET, in whose columns this article or notice has appeared which is complained of. You have up to this moment paid the greatest possible attention to this case, and I am sure you will continue to do so until the end, because I expect you realise, and it is not necessary for me to say, that not only are the personal interests of the plaintiff and the defendant involved in this, but it so happens that there is a great question of considerable public importance involved, because upon your verdict will largely depend the question as to whether the wholesale dissemination of this liquid containing, as I shall submit to you, very considerable quantities, and dangerous quantities, of certain drugs is defensible or is not defensible; and whether it is to continue under existing conditions or not, possibly may depend to some extent upon your verdict in this case. My learned friend has said that THE LANCET newspaper is an old and well-established paper and a well-conducted paper, and he has pointed out that it is a paper which comes into existence for the purpose of circulating mainly, if not entirely, amongst the medical profession, and that it deals with medical questions and questions of interest to professional gentlemen. You will have presently to say whether the language THE LANCET used with reference to this specific was under the circumstances in excess of what they were justified in using; and of course, I ask you, in considering that question, to bear this in mind, if I may use the expression it is a case of doctor talking to doctor, and therefore of a person talking to another person upon matters about which both of them have a considerable amount of common knowledge which it is not necessary to express. Now it is very necessary to bear that in mind when you come to consider the language which was used. The matters which I suggest to you were common knowledge, both to the person, the editor of the paper for this purpose, and the persons for whose benefit these notes are written, are two. First of all it was common knowledge what the law of this country is with reference to the sale of poisons. I want just to say a word to you, and it shall only be a word, about that. Mr. Tucker has told you that to his knowledge every country by its laws in some way or another safeguards the public against the indiscriminate sale or use of poisons, and in this country those safeguards are contained in what is known as the Pharmacy Act; and they are very exact. They are of two kinds. First of all it is provided that nobody, unless he is a registered chemist, shall be allowed to sell these poisons at all. Of course, the object of that is that the sale of these poisons shall only be entrusted to a certain specially qualified class of persons, a man who has had a certain training, a man who has had a certain experience, and a man who has passed certain examinations before he can become registered. Therefore, that is the first precaution; that is the first safeguard. The other is this, and it depends upon the character of the poison: there are some poisons with regard to which it is only necessary, if they are sold by a chemist, to state upon the bottle or the box the name of the article and the word "Poison," with the name and address of the seller; and in that class of article you have this protection, you have the protection that it can only be sold by a chemist; you have the protection that everybody into whose hands that bottle comes shall be warned that it is poison, and shall be told what it is. In the other class (and into this class come both preparations of atropine and cocaine and its salts) the precautions are much wider and stricter. In that case the chemist may only sell the article if the purchaser is known to, or is introduced by, some person known to the seller; there could be no indiscriminate sale in such a case; it can only be sold by the chemist to some person known to him or to some person introduced by a person known to him; and entries must be made in the Poisons Book of the date of sale, the

I believe your chest is weak? You have weakness of the respiratory system?—No, I am suffering from bronchial catarrh.

Since that time in 1894 when you felt the symptoms of asthma about you have you resorted to Tucker's specific?—Yes.

What has been the effect of it from that time until this whenever you have had occasion to resort to it?—It is a difficult question to answer. From that day to this if ever I have felt uncomfortable, and I have got hold of Tucker's atomiser, in half a minute or, we will say, one minute, I am quite right.

Mr. Eldon Bankes: I think he must have made a mistake about 1894.

Mr. Duke: No, it could be bought, although it was not in London. You say you bought it in 1894; where did you get it?—I got it from Holborn.

Mr. Justice Ridley: Are you sure of your year, because we have evidence that he was not in Holborn as soon as that?

Mr. Duke: My learned friend Mr. Bankes suggests from the letter you wrote about it that you are mistaken in your year, and it was 1899?—I did not say 1899.

Mr. Tucker says it was 1899 or 1900.—What did I say?

1894.—I meant 1904.

Mr. Eldon Bankes: You are wrong again. It has not improved your memory.

Mr. Justice Ridley: What was the year. We want to know as near as you can tell us?—I got it in 1894 to the best of my recollection.

Mr. Duke: You bought it of Mr. Tucker, who is here?—Yes.

He came to London in 1899, so you are mistaken.—I see.

Mr. Justice Ridley: I thought you might have bought it in America?—No, I did not; I never was there.

Mr. Duke: Having regard to the period during which you used it, can you tell us whether there is any craving for the use of the thing if you have not any ailment which requires the use of it?—The only thing that could make me use it at all events would be the fear of an attack coming on, no other feeling.

Mr. Eldon Bankes: I have no questions.

Travers William Pickmeyer, *examined by* Mr. Smith.—What is your occupation?—None now; I am independent.

What were you formerly?—A wine merchant.

Do you mind telling us how old you are?—51.

Did you suffer from a liability to asthma?—Yes.

How long have you suffered from it?—Since 1903.

Was it acute, or did it become acute?—It gradually became worse.

You had, I think, severe attacks?—Yes.

The effect of the attacks on your general health was bad?—Certainly.

Did you hear of Mr. Tucker's asthma specific from someone?—Yes.

Did you obtain it on the trial basis?—No; I bought it outright.

What was the effect upon your health of its use?—How do you mean?

When you got it first; we will go by steps?—It relieved me at once.

Has the relief continued?—Certainly.

Has it had any injurious effect at all upon your general health?—None whatever. I played in three cricket matches last year.

Has it produced in you the slightest desire to use it except as a preventive or a cure for an attack?—I never use it except I feel an attack coming on.

It has never produced any desire in you to use it?—None whatever.

Mr. Eldon Bankes: I have no questions.

Mr. Duke: There is this question of the suggested craving for cocaine or something. My learned friend has not cross-examined my witnesses with regard to this matter. I do not want to go on putting witnesses into the box.

Mr. Justice Ridley: I take it it is not necessary for him to do so after he has made the suggestion which he did. You must take it that he disputes it.

Mr. Eldon Bankes: I do not suggest that any of these witnesses have the cocaine habit, or any desire to have it, and I do not dispute that out of the 25,000 my learned friend can call a great many who have not.

Mr. Justice Ridley: I was a little inaccurate. While not disputing what they say he does say it might produce and would be liable to produce that in others. That is the case you have to meet.

Mr. Eldon Bankes: If my friend will give me the number of people he has got here I will admit it.

Mr. Duke: My learned friend must take his own course but if my learned friend persists in the allegation that the use of the atomiser produced an unwholesome craving for cocaine, I must go on.

Mr. Eldon Bankes: In certain cases it does.

Mr. Justice Ridley: Have you got the people here?

Mr. Eldon Bankes: No; I have evidence about it.

Mr. Justice Ridley: Have you got the people who use it and have got the craving?

Mr. Eldon Bankes: I have got the doctor who treated them.

Mr. Duke: The people who use this inhaler?

Mr. Eldon Bankes: Yes.

Mr. Duke: Then I must go on. I am sorry that my friend in giving particulars of his defence did not give any particulars of this matter. There is no suggestion of it in the defence, and I shall have to consider what the position is if my learned friend tenders the evidence.

Mr. Justice Ridley: You must take your own course. Perhaps you can take them in batches.

Arthur Stephen Lowry, *examined by* Mr. Duke.—Are you a wine merchant?—Yes.

You live at Beckenham?—I do.

Were you for many years a sufferer from asthma?—About 50.

Mr. Justice Ridley: How old are you?—I am 55.

Mr. Duke: From your childhood you have been liable to attacks of asthma?—Yes.

Had you had medical attendance for it?—Yes, many doctors.

And a great variety of remedies?—Very great.

Did your liability to asthma continue?—Yes, the acuteness of the attacks decreased slightly but the frequency increased.

Down to what period?—I think six or seven years ago.

How do you mark the time?—That is when I got the Tucker's atomiser.

Did you get it on trial?—I did.

Did you pay for it when you had had it about a week?—No, I did not wait more than a day or two.

You waited a day or two and found that the use of it was beneficial to you?—Yes, I had had my three guineas' worth or three pounds' worth in a day or two.

Did you get it then at a time when you were actually suffering from an attack of asthma?—Yes, it had been recommended to me by a friend, but I did not take very much notice then, but one day I was walking across Holborn Viaduct and breathing very badly and I saw the name "A. Q. Tucker." That decided me. I went in and tried it on the spot and had instant relief.

So far as you were concerned, was there any fraud, did you consider, in your being charged £3 for it?—Not in the least.

You paid what you bargained to pay for it?—Certainly.

Was there any element of deceit which you have since discovered, any imposture upon you?—Not an atom.

How could it compare as regards expense since the time you have had it with the period during which you had not got it, when you were suffering from asthma?—My expenses in connexion with asthma must be infinitesimal to what they were before I had it.

Speaking generally, what has been your condition with regard to asthma since you have had the atomiser and the specific?

Mr. Justice Ridley: He says it gave him immediate relief.

Mr. Duke: Very well, I will leave it at that.

Do you find any craving for the stuff when you have not had the trouble?—None whatever.

Mr. Eldon Bankes: I have no questions.

Francis Henry Venn, *examined by* Mr. Duke.—You are the solicitor for the plaintiff?—Yes.

When did you first come into communication with the plaintiff?—In 1902.

Were you at that time very subject to attacks of asthma?—Yes, I was suffering severely at that time.

What effect had they upon your condition and your ability to follow your profession?—I was subject to attacks that if the jury should find that this does make an imputation upon the plaintiff's character, that he has been guilty of fraud, you must prove it to be the fact if you wish to have a verdict.

Mr. ELDON BANKES: I will bear in mind what your lordship says. I do not want in the least to escape from or evade the point, but what I do want to put before the jury are certain considerations; because, gentlemen, my case is, if I may summarise it—perhaps it will be the simplest way to summarise it after what my lord has said, and then perhaps amplify it a little bit more, if you will allow me to do so—what I say in substance is this, that for a man who has no medical knowledge or skill at all, and who has no knowledge of the constituents of the specific which he sends out broadcast, to send out advertisements saying that the stuff of which he knows nothing is harmless, to send it out without any of the warnings with which the law says he ought to accompany it, and to send it out, not only without those warnings, but with an encouragement to use this stuff in unlimited quantities, and if you find that the stuff itself does contain poisons in dangerous quantities, if you find it is very likely to be taken by people who are suffering from diseases to whom it will be actually harmful, when you find that, and, on the top of it all, instead of these warnings he adopts a system which enables him to put upon it the Government stamp, carrying to many minds the indication of genuineness, then I say it is fair to say of that man that his system of trading is a fraud upon the public. That is in substance what I say this article means, and that is in substance what I submit the facts prove. That is, I submit, what we did say, and that is, I submit, language which is not in excess of the particular occasion. Now I want this afternoon badly to call some of these gentlemen before you whose time is valuable and whom I may not be able to call on another occasion, and therefore I want to curtail what I have got to say at this moment within reasonable limits; but I do want you to bear this in mind when you are considering this case, and our evidence and the evidence for the plaintiff, I ask you to bear in mind these observations with reference to this particular class of medicine; whether you call it a quack medicine or whether you call it a so-called quack medicine I do not mind; but bear this in mind, that no man who has got one of these things to sell can ever make a success of it unless it contains a drug which will be beneficial to a considerable number of persons. He would never sell it at all unless it was for that. This specific contains cocaine, a most powerful and potent agent, which undoubtedly does operate to deaden the mucous membrane of a person who is suffering from asthma or any similar disorder; and there is no doubt that if you administer cocaine to such a person, particularly, probably, in conjunction with atropine and these other matters which I have referred to, it undoubtedly does bring relief to him or her, because it deadens the mucous membrane. Therefore, of course, to a considerable number of persons it will be a benefit. Mr. Tucker could not have sold the quantities he has sold unless it was a benefit. No person who has made fortunes in selling similar remedies or other quack remedies could have made the money he did unless the specific contained some drug which was of use under certain conditions; but the danger of doing that is this: You send it out without knowing the particular disorder from which the person is suffering to whom you send it. You do not know the condition of his nervous system; you do not know the condition of his heart; you do not know whether he is suffering from consumption. All you know is that he writes and tells you that he is suffering from asthma, which, as the plaintiff says, may be an entire misconception of his condition. Therefore, when you send your specific out you do not know, and you have no opportunity or means of knowing, whether it is going to do good or harm to the particular person who happens to receive it. That is the danger of all these quack remedies; that is the ground upon which they have from the beginning been attacked. Nobody suggests that they cannot do good and nobody suggests that in certain cases they do not do good, because they never succeed unless they did do good in certain cases; but what is attacked and always has been attacked is this, that you have no right to send out drugs of this character without first of all a careful examination which will enable you to judge whether it is a proper case in which to administer the drug, and, furthermore, you have no right to send it out, to prescribe it to a person, unless that person will be under your observation, and you will be able to see whether or not the drug is doing him harm or doing him good. Therefore, if that is right, you will follow that in this case or in any similar case it is always possible to call a large number of persons who have benefited by the specific. Just bear this in mind; according to Mr. Tucker's own case he has got or had 25,000 patients. What proportion of those do you think he has benefited? I do not dispute for a moment that he has benefited a considerable proportion. Therefore, having 25,000 patients in all these years, he can call a very large number of persons who have benefited. But what about the people who have not benefited? He, of course, does *not* call those. They are not people who go parading in the street the fact that they have taken Tucker and suffered damage from it. We can only call before you persons who, in their professional career, have had to deal with people who are suffering and seriously suffering from what I think some of them, at any rate, have called the Tucker habit. Please bear that in mind in considering this case. Of course, they can bring people who have benefited by the treatment, and of course they bring the people who have benefited and leave at home the people who have not benefited. It would seem to me childish to ask gentlemen who come into the box there one after the other whether they had any temptation to the cocaine habit. It is obvious they had not. It is obvious that they had never used this thing to excess. It is obvious that they were not susceptible persons, and they were selected because they were persons who had benefited by the treatment.

Now let me say a word quite shortly to amplify those points which I made before you a moment ago. This specific, instead of being sent out under the precautions enumerated in the Poisons Act, instead of being prescribed by persons who would be able to watch the effect upon the patient—am I exaggerating at all when I say that it is sent out indiscriminately by the gallon? It is sent out by a man who would have you believe that he does not know what it contains; sent out by a man who has told you in his own language that so far from warning people as to the amount that they should take, or the extent to which they should use it, he impresses people that they should use it—I forget the exact expression he used, I think it was "We insist upon the frequent use"; sent out by a man who comes here and defends it in this language. I say to him, "Do you defend sending out indiscriminately these large quantities of liquid without ever inquiring what the constituents are, or what harm they will do in certain cases?" and his answer is "Yes." It is sent out under those conditions with a statement in print that it is absolutely harmless, and sent out with a statement in print, not only that it is absolutely harmless in general, but, remember, specifically stating that it is harmless in cases of weak heart. The exact words are: "Any asthmatics who have organic heart disease or weak heart action can use the remedy with perfect safety." I suggest to you that under those circumstances there is every justification for the use of strong language, every justification in the interests of the public for the use of strong language, and that we have not in the note that we issued in THE LANCET of that date exceeded the proper limits of such language. I ask you one further question—to consider the bearing of the price at which this article is sold. I am not going into this in detail now because I have told you that I am very anxious to call my evidence, but I do want to make my position plain about that. Of course, a man is entitled to charge as much for a thing as people will give him for it, but you have to consider the circumstances under which that price is charged. You have to consider this, that this kind of advertisement appeals largely to the poorer classes, and appeals largely to men of the Cushing class—fitters and people earning weekly wages, to whom this sum of £3 is a very considerable item of expenditure. Now a man may say, "I am justified in charging anything people will pay me for this thing." That may be, if you are satisfied that the person making the charge has taken every precaution to see that before he takes the man's money it is not only going to give him temporary relief but that it is going to do him some substantial good and is not going to do him harm. Mr. Tucker, through his counsel, claims credit for the fact that he allows this fortnight's trial. You must guard yourselves, I submit, from being led astray by that. Of course, Mr. Tucker sends out a powerful drug which must necessarily give relief; he is quite certain that if he sends out this specific to persons who suffer in the way that asthmatic persons do, and will grasp at any remedy, within a fortnight they will be so gratified with the relief

Would you administer cocaine for instance by correspondence?—I might.

Would you treat a patient by correspondence with cocaine although you had never had an opportunity of examining him?—Cocaine is very often used for the eye. I might use it as drops for the eye as a prescription by correspondence.

I ask you, Would you in your profession treat any patient by correspondence with cocaine for any purpose without having had an opportunity of examining him?—If Tucker's specific contains cocaine I would prescribe it to anybody by correspondence for asthma.

We will leave Tucker out of the way for a moment. I ask you generally so that I shall be able to form an opinion about it. Would you as a professional man——

Mr. Justice RIDLEY: Surely that was a very sensible answer of his. If it contains cocaine he would recommend it because it is a remedy for asthma, that is why.

Mr. ELDON BANKES: You say you would advise it without having had an opportunity of examining the patient?—I would in those doses.

Without giving the patient any warning that it contained cocaine?—I should not think it necessary to give him any warning.

And you notice, do you not, that, as administered by Mr. Tucker, there is no indication that the patient ought to be careful as to its use?—I have never found the necessity. I have recommended it in numbers of instances, and numbers of my patients use it.

Do you think that before recommending it you ought to be quite sure that the person is suffering from asthma?—It would not do him any harm.

Do you not think it would do him any harm whatever his condition is?—Undoubtedly it would not.

Do you think if the patient for instance were suffering from phthisis you could safely administer this specific?—Quite safely, and if he was suffering from bronchial catarrh it would relieve that catarrh.

Do you give that answer without knowing what is in it, or accepting the suggestion that it contains cocaine and atropine?—I give that answer on my knowledge of the specific and its action on patients.

Have you ever had it analysed?—I have tried to have it analysed, but they were unable to give me a fairly good result.

Unable to give you any result?—Yes.

Could not they tell you whether it contained cocaine?—They could not.

It could not have been a competent analyist, could it?—I judged not.

You sent it to somebody who cou~~ld not~~ analyse it, and he said he could not?—Well, he was an analytical chemist.

Supposing I were to satisfy you that it contained both cocaine and atropine, would you, as a professional man, prescribe that for anybody without examining him?—I should, decidedly, because of the small minute doses in which they must be, because of the effect I know it has upon myself.

Of course, when you speak of small minute doses you mean the amount which is vaporised by each compression, or, we will say, by a dozen compressions?—In 100 compressions.

The amount, of course, which a patient absorbs into his system depends entirely on the extent to which he uses it?—Decidedly.

Mr. Justice RIDLEY: Of course it does; how could it fail to do so?

The WITNESS: But he stops using it when he gets relief.

Mr. ELDON BANKES: Supposing I could satisfy you that a patient acquired the cocaine habit by the use of Tucker's specific would you then cease to prescribe it?—I should not.

Although I could satisfy you that a patient had acquired a cocaine habit?—Although you could satisfy me that a dozen patients had I should still prescribe it.

Without seeing the patient?—I should have no hesitation at all if I was told he was a martyr to asthma.

Mr. Justice RIDLEY: You have recommended it, I understand?—Yes, in numbers of cases.

Mr. ELDON BANKES: Let there be no mistake. You would continue to prescribe it without *supervision* even if you were satisfied that 20 patients had acquired the cocaine habit through it?—I should.

Re-examined by Mr. DUKE.—In your experience is there any real risk of a person who uses this remedy acquiring any pernicious habit by the use of it?—Not the slightest.

It has been suggested that there is a grain and a half of cocaine in an ounce of this fluid?—Yes.

In an ounce there are 480 grains, are not there?

Mr. ELDON BANKES: No, 440, is it not?

Mr. DUKE: I am told according to the best modern science it is 437½. They have advanced since I learned. Take 440 grains to an ounce. One and a half grains are suggested to be cocaine. That will be 3/880ths; it is 1½ over 440, 3 over 880—about 1/300th part of an ounce roughly will be cocaine; that is arithmetic. How long will an ounce last you in use?

Mr. Justice RIDLEY: If the ounce lasts for six months—that is the evidence—you get 1/300th part of an ounce in six months.

Mr. DUKE: How many drops are converted into vapour, do you think, when you press the bulb?—I should say not one drop, judging from the time it lasts—not one minim, I should say.

You do not think the discharge of vapour on each compression discharges one minim or one drop of the contents of the bottle?—No, I do not—one minim.

How many minims will there be in 440 grains?—There are 60 minims in a drachm and eight drachms to the ounce.

So there will be 480 minims in 440 grains. Take it roughly a minim to a grain. At each of these discharges you discharge 1/480th part or thereabouts of one grain of cocaine, according to my learned friend?—That is a possible figure.

The vapour which you produce fills the cavity of the lungs?—Yes.

And a great part of it is discharged from the mouth?—It is.

And the mischievous part, if it is mischievous, must be that which adheres to the lungs; it will not be that which is discharged into the air?—I should say not.

I suppose you cannot give me a measure in volume of the part of the one grain that adheres to the lung?—I could not.

In order to find out what portion of one grain of cocaine, or of 1/400th part of a grain of cocaine runs the risk of passing into the system when the patient inhales from the atomiser you have to work out those calculations?—It could be tested and found out.

Do you think there is any occasion for testing and finding it out after the practical experience you have had?—I do not.

Your patients have used this remedy?—They have.

Beneficially or not?—Very beneficially. I have one case of cure by it. She was in bed for three winters with bronchial asthma, and after she used that she gradually recovered and has not had an attack since.

That patient, in your judgment, has been cured by the use of this remedy?—She has.

Dr. JOHN DUNNELL RAWLINGS, *examined by* Mr. DUKE.—I must put the same questions to you as I did to Dr. Clark; you are attending here on subpœna?—Yes.

And, as I understand, against your will?—I did not want to come, certainly.

So I have no proof of your evidence?—No.

You are a registered medical practitioner?—Yes.

Have you yourself been subject to asthma?—No.

Who was it in your household who required a supply of the Tucker specific?—Nobody ever has.

Mr. Justice RIDLEY: Nobody in your house?—No.

Mr. DUKE: Then who was it in your practice who required it?—I do not say it was required, but I suggested to one of my patients that she should try it.

How long ago was that?—I think about a couple of months.

Was it tried with beneficial results, or not?—I really cannot say. The patient herself thinks it did her a certain amount of good. Her attacks have not been severe, and they have always been in the night, so I have not seen them. I have had no opportunity of judging it myself.

But the patient thought it did her good?—To this extent that she did buy the thing, but she was not at all enthusiastic about it. At the end of a fortnight she was still quite uncertain whether she would buy it or not.

Although she was uncertain, did she buy it?—She did buy it, yes.

And did she buy it with your approval?—Yes.

Had you heard that the specific might include cocaine?—Yes.

Did the lady get her ounce of specific, or whatever it was?—Yes.

And used it at her discretion?—Yes.

May I take it that you did not consider that there was a

Did you take those two bottles on the same day, the 8th July, to Mr. Vasey?—I handed it actually to Dr. Sprigge, but it reached Mr. Vasey, I think.

It was handed to Mr. Vasey, the analyst?—Yes.

That was in the same state when you handed it to him as when it was received?—Exactly, with the exception that I had put the label on that I had purchased it.

What did you do with the second bottle?—We kept it in the safe, I think. On the 22nd November I took that to Dr. Willcox, at the St. Mary's Hospital, Paddington.

You left it there fastened up, I think, for him, did you not?—Yes, that is so.

Mr. SMITH: I do not ask anything.

Dr. WILLIAM HENRY WILLCOX, *examined by* Mr. ELDON BANKES.—I think you are a Doctor of Medicine, a Fellow of the Institute of Chemistry and a Fellow of a number of other societies?—Yes.

I think that you are the scientific analyst to the Home Office?—Yes.

On the 22nd November, 1907, did you receive at St. Mary's Hospital one of these two packages?—Yes.

Did it contain a glass bottle?—Yes.

Is that it which you have there?—Yes, that is the one.

It contained a quantity of dark coloured fluid?—Yes.

Mr. Justice RIDLEY: You analysed the contents; let us get on. There is no doubt about that, is there?

Mr. SMITH: No, my lord.

Mr. Justice RIDLEY: It is no use making such a fuss.

The WITNESS: I analysed the contents.

Mr. ELDON BANKES: Will you give me the result of your analysis? I think the simplest way will be to give it in grains per fluid ounce?—Yes. The bottle contained 31 cubic centimetres, that is a little over an ounce of liquid. It was a dark reddish-brown liquid, it had an aromatic smell, and it contained some alkaloids.

Can you tell us what the constituents of the bottle were?—Yes, I will go on with that. The total amount of alkaloids present was 3·15 grains in the fluid ounce. The alkaloids present were two in number, cocaine and atropine.

Mr. Justice RIDLEY: How much was the cocaine?—The cocaine was 2·28 grains.

And how much was the atropine?—0·87 grain. There was also present nitrite of soda, 15·25 grains in the fluid ounce; and glycerine was present, between 20 and 30 per cent. I did not estimate the exact amount.

Mr. ELDON BANKES: Between 20 and 30 per cent. by volume that would be?—Yes, then there was some balsam present, or gum benzoin—balsam.

Anything else?—Minute traces of mineral matters which were of no importance.

Was there oily matter?—Yes, oily matter.

And vegetable colouring matter and so forth?—Yes.

What were the active ingredients in the specific?—They were cocaine, the atropine, and the nitrite of soda.

Was your analysis an exhaustive analysis in the sense that it exhausted the active ingredients?—Yes.

Can you tell us what the actual cost of sufficient of these ingredients to make an ounce of liquid would come to?—The actual cost would be about 3*d*. That would not include the cost of the time in making it up, but it is the cost of the ingredients.

What is the action of these two alkaloids, cocaine and atropine?—They are both poisons. Shall I take cocaine first?

Yes, if you please.—Cocaine is a local anæsthetic; that is, it takes away the sensibility of the part.

Mr. Justice RIDLEY: It is what a dentist uses when he wants to take a tooth out?—Yes.

That is the English of it?—And it is a powerful depressant of the heart.

Mr. ELDON BANKES: You have finished what you have to say about cocaine?—Those are the main actions. I can go into it at great detail, if you like.

No, we do not want great detail. Now, as to atropine?—Atropine quickens the heart's action, and it is used a great deal for allaying spasms, for instance the spasm of the bronchial tubes. It is a deliriant poison if it is taken in moderately large doses.

I think that you prepared a report, did you not, in conjunction with Professor Pepper, in connection with this specific?—Yes.

Mr. Justice RIDLEY: You say it is a deliriant poison?—Yes, it produces delirium.

Mr. ELDON BANKES: I will just go through the points of your report. There was nothing on the bottle, was there, to indicate that it contained a poison?—No.

What would be the effect to the taste of its containing glycerine?—It was rather sweet to the taste.

Mr. Justice RIDLEY: Is that material?

Mr. ELDON BANKES: Assuming the bottle to be left about with this sweet tasting stuff with no label upon it, do you think that in itself is a source of danger?—Certainly, it would be dangerous.

And why?—It might be drunk in mistake by a child, for example.

With regard to true asthma do the symptoms of asthma closely correspond with the symptoms of other diseases?—Yes.

Will you mention some?—In some forms of kidney disease the symptoms are identical; symptoms occur which are identical with those of asthma. In fact the name uræmic asthma has been given to that condition.

I mentioned Bright's disease; would you include that?—Bright's disease is the term which is used to cover that class of case.

Mr. Tucker laughed at it, but you say that the symptoms of Bright's disease——I prefer you to use the words "kidney disease," which is the same thing really—that is, some cases of kidney disease have symptoms exactly identical with those of asthma. I have seen several.

Will you mention one or two other ailments with similar symptoms?—Yes, in some of the forms of heart disease there are attacks of shortness of breath which only a medical man would distinguish from asthma.

Is there any other?—In lung disease, called emphysema, there is shortness of breath and a condition of things which closely resembles asthma. Some forms of bronchitis have symptoms closely resembling asthma.

I think you mentioned phthisis, did you not?—No, I did not; I have not come to that. Some cases of phthisis might present symptoms like those of asthma. As a rule the cases would not be the same, but some would undoubtedly give symptoms very like those of asthma.

In your opinion, what might be the effect of giving cocaine, even in small quantities, to patients suffering from any one of these diseases which are not asthma?—In the case of heart disease, cocaine would be a dangerous drug to be given at all. In kidney disease it ought not to be given. Shall I go on with the other diseases?

Yes.—In cases of advanced consumption it should not be given. In bronchitis, in my opinion, it would be better not to give cocaine, and also in emphysema.

Mr. DUKE: I think you mentioned two or three of these before.

Mr. ELDON BANKES: It is said by Mr. Tucker that the quantities of cocaine which are given by means of his specific used through the spray are so infinitesimal that they could not do any harm. What do you say about that?—I think that to people suffering from disease of the heart a small dose of cocaine would be harmful.

When you say a small dose, you mean such a dose as he could receive by this spray?—If it were used for a long time I should think such a dose might be given.

Apart altogether from any of these diseases which you have mentioned, are there certain persons extremely susceptible to cocaine?—Yes.

In your opinion is it safe to give cocaine even in this way indiscriminately?—Not indiscriminately.

Why not?—Because if it were given to a person suffering from one of these diseases which I have mentioned it might produce harmful effects.

But I am asking you now to deal with the case of a person who is not suffering from one of these diseases which you have mentioned, but who is susceptible to the influence of cocaine. Would it be harmful to administer this specific to such a person?—I should think that it would be unwise.

Have you any experience of the cocaine habit?—Yes.

Is that, in your opinion, easily produced?—Yes.

In your opinion would the continued use of Dr. Tucker's specific be likely in some cases to produce it?—It might be.

What is the primary action of the spray produced from this specific? How does it act to relieve the immediate attack?

Mr. DUKE: We both mean the same thing, I suppose—the vapour? We call it the vapour.

Mr. ELDON BANKES: Yes.

The WITNESS: The spray would come into contact locally with the bronchial tubes.

elapse without your using it at all?—Never at all; never a day. I have used it this morning, and I used it last night.

I understand that using it as frequently as you use it, which appears to be very frequently, your ounce will last you from 12 to 18 months?—Yes.

Do you notice in the memorandum Dr. Tucker says that the fluid will cost you 8*s.* an ounce, which lasts from two to four months?—No, I have not read it.

So that Dr. Tucker assumes that a person following his instructions will use this remedy so much more frequently than you do, that a person will exhaust it in from two to four months, whereas with you it takes from a year to 18 months?—I can only give you my experience. Unless I drank it I could not get rid of it in that time.

Mr. SMITH: You do not drink it?—No, I do not.

Dr. WILLIAM BATSON, *examined by* Mr. SMITH.—I think you also are here in attendance on subpœna, and you have given no statement to the plaintiff?—Quite so, I have not given any statement.

Have you, or some of your patients, suffered from time to time from asthma?

Mr. Justice RIDLEY: You are a medical practitioner?—Yes.

Mr. SMITH: Do you mind telling me what your qualification is?—I am a Licentiate of the College of Physicians and a Member of the Royal College of Surgeons.

Have you from time to time sent for Mr. Tucker's specific?—Yes.

Will you tell my lord and the jury for whose use you sent for it?—For my own.

Have you been a sufferer from asthma?—Yes.

For many years?—Yes, 50 years.

In that time you have tried many remedies probably?—Yes.

What result did you find from the use of this specific and atomiser?—A great benefit.

And you have not felt the cocaine taste growing on you?—No.

Cross-examined by Mr. ELDON BANKES.—Did you know it contained cocaine?—I did know it, yes; at least I am told it does.

Did you know of that from communication with other doctors?—I knew it was analysed in 1903 by an analytical chemist.

And it had become more or less common knowledge in the profession, had it not?—Yes, quite.

It had become common knowledge in the profession that this contained cocaine?—I think so.

And you think that was so in 1903?—I think that is the date.

Do you recognise that cocaine is a drug which should only be prescribed under most careful restrictions?—Yes, certainly.

Do you defend a system under which cocaine is supplied indiscriminately without any examination of the patient, or any warning that the specific contains cocaine?—It depends upon the dose.

But under any circumstances would you justify selling cocaine indiscriminately, even in small quantities?—In minute doses, why not?

Have you had any experience of the cocaine habit?—No.

Then you have no experience as to how readily the habit is acquired, even by the taking of very minute doses?—No.

Would it modify your view if you were satisfied that patients had acquired the cocaine habit from the use of Tucker?—I should think it was impossible from my own experience.

But assuming it is shown to have happened, would that modify your view?—I should be most sceptical. I should think it could not possibly happen.

Mr. Justice RIDLEY: You mean from this specific used as directed?—Yes; I have used so much of it.

Of this specific?—Yes; I am an asthmatic.

Personally, you mean?—Yes.

Mr. ELDON BANKES: But you know, do you not, that the susceptibility to cocaine varies enormously in different persons?—Yes, like every other thing.

Mr. Justice RIDLEY: How long does an ounce last you?—I am afraid only three months; sometimes less.

Mr. ELDON BANKES: Why do you say you are afraid?

Mr. Justice RIDLEY: It shows what a bad sufferer he is.

The WITNESS: The more I use it, the more expensive it is.

Mr. Justice RIDLEY: Is that your reason? I thought you meant the greater the disease was.

Re-examined by Mr. SMITH.—You are familiar, I take it, with the ordinary recognised remedies for asthma?—Yes.

And I daresay both in your own case, and in the cases of other patients, you have had to try them from time to time?—Yes.

As compared with them have you derived more or less relief from the use of Mr. Tucker's specific?—Yes.

You mean more from Mr. Tucker's specific?—Yes.

Than from any of the ordinary remedies with which you are professionally familiar?—Yes.

Mr. Justice RIDLEY: It is the best remedy you know?—Yes.

Mr. SMITH: You have never felt that you have been defrauded by paying £3 for using it?—No.

Mrs. KIRTON PIMM, *examined by* Mr. SMITH.—I think you have suffered from time to time from attacks of asthma?—I have suffered with asthma since 1891.

Did it cause you great inconvenience?—Yes, I have been in my bedroom for a week at a time, and not able to go out.

Your general health suffered, I think, from the attacks?—I have been an entire wreck. I was quite a wreck five years ago.

Did you consult doctors for relief?—Yes, I constantly had the doctor in the house.

Was he able to give you relief?—No, not at all.

I think you tried many remedies?—I tried everything I could think of.

About five years ago did someone bring Mr. Tucker's specific and atomiser to your notice?—Yes, they recommended it to me as having cured them between four and five years ago.

On that recommendation you sent for the atomiser, and for some of the specific?—Yes, I wrote to Herne Hill for it.

Did you get it on trial?—Yes. I paid for it just before the fortnight.

What was the immediate effect of it?—It was a relief instantly.

That is five years ago, and has the relief continued?—Yes, I have never been laid up a day since.

We perceive you are no longer a wreck?—No, I am not.

But you say you have never been laid up since?—No, not once since. I can work now, and I could never work before without bringing on asthma.

It has really given you back the capacity for doing work? Yes.

Mr. Justice RIDLEY: Have you acquired the cocaine habit?—No, not at all.

Mr. ELDON BANKES: I have no questions.

HERBERT HENRY NORMAN, *examined by* Mr. SMITH.—Are you a reporter on the staff of the *Southwark Recorder and South London Gazette*?—I was in 1906.

And at the beginning of 1907, I think, too?—Yes.

Did you attend the inquest which was held on the deceased man Cushing on the 1st of January, 1907?—Yes.

Did you take a shorthand note of the proceedings?—No, not a shorthand note.

But you took a note?—I wrote the case as it went along.

You were not reporting it sufficiently fully to make it worth while to take a shorthand note?—No.

Was the paragraph headed "Believed in Quacks" which appeared in the *Recorder* on the 5th of January, 1907, the product of your pen, if I may so express it?—Yes.

Mr. Justice RIDLEY: Is that the one referred to in the libel.

Mr. ELDON BANKES: I have not seen that.

Mr. SMITH: No, I will give your lordship a copy of it. (To the witness) Would you mind looking at that to identify it? (Newspaper handed to the witness).

Mr. Justice RIDLEY: It is the newspaper report referred to in the libel?

Mr. SMITH: No it is another one. Your lordship will see why I call the evidence. "Believed in Quacks.—The circumstances attending the death of Alfred Albert Cushing, aged 42, late an engineer's labourer, living at 132, H Block, Queen's Buildings, Borough, were enquired into at the Southwark Coroner's Court on Tuesday. The widow said her husband had suffered from asthma and bronchitis for 12 years and used to doctor himself with almost anything he was told of. He had no faith in doctors, saying they did him no good. On Saturday, 23rd ult., he was obliged to keep his bed, and witness called in a district nurse. The nurse sent for a doctor, who pronounced life extinct. Dr. G. A. Paton, of Marshalsea Road, who made a post-mortem examination, that commodity No. 21 is there? (Book handed to the witness.)—Yes.

And is what purports to be a description of it there?—Yes.

Oppenheimers are careful, accurate people in sending out these things, are they not?—Yes.

Just tell us what No. 21 is said to consist of?—It consists of atropine one-third of a grain in the ounce, cocaine hydrochloride two grains in the ounce, a solution of hyponitrous acid gas to saturation, and balsamic extracts to the ounce.

Are Oppenheimers selling that as being substantially the same as the preparation of an American doctor which is being sold in this country?—I did not know that they were, but I see that it is stated there.

Do you know any other preparation of an American doctor except the Dr. Tucker specific?—There may be many others.

Do you know of any others?—I do not know of any.

That is what I asked you.

Mr. Justice RIDLEY: *What does it say?*—Shall I read it out?

Mr. DUKE: Read it out, if you please.—"Many inquiries from important medical men having reached us regarding a certain preparation for asthma recommended by an American doctor, we introduced our Neboline compound No. 21 which is similar in every respect to the preparation in question, and which from the reception accorded to it seems to meet all requirements." *A very fraudulent transaction, is it not?*

M. Justice RIDLEY: That is by a chemist, is it not?

Mr. DUKE: It is by the most eminent firm of wholesale druggists.

Mr. Justice RIDLEY: There is the balsam, and there is the cocaine, and there is the atropine?—There is no glycerine there, and no nitrite of soda.

Mr. DUKE: You think they did not hit it quite as accurately as you have?—I should say undoubtedly not.

Mr. Justice RIDLEY: It appears to me, though I may be wrong, that what you place chief reliance upon is the cocaine and the atropine being there?—Yes.

Mr. Justice RIDLEY: *They are there, you know.*

Mr. DUKE: Will you give me the book, please. (Same handed to learned counsel.) "Many inquiries from important medical men having reached us regarding a certain preparation for asthma recommended by an American doctor, we introduced our Neboline compound No. 21 which is similar in every respect to the preparation in question, and which from the reception accorded to it seems to meet all requirements." Then there is this note in italics: "*Practically a specific for asthma.*" Then there is this further statement that the specific can be purchased wholesale by the profession of Messrs. Oppenheimer at 3*s.* 6*d.* an ounce without any Government stamp?—Yes; I did not see that there, but I have no doubt it is there.

You will take my word for that, I am sure, as my learned friend will?—Certainly.

3*s.* 6*d.* an ounce when the wholesale druggist is retailing it either to the medical man in the provinces or the suburbs who dispenses his own physic, or to the pharmaceutical chemist; that is so, is it not?—Yes.

What price do you think it would arrive at before it got out to the public?—It would be impossible to say, of course.

It might reach almost anything, might it not? I want to know this as you understand these things; do you think the conduct of the medical practitioner or the chemist who buys this—first of all with regard to Oppenheimer's compound, you have told us that Oppenheimer's can make this up at how much an ounce, did you say?—I have not expressed an opinion about Oppenheimer's preparation, but about the analysis that I made.

But there are more ingredients in yours than there are in Oppenheimer's, and so theirs would be cheaper than yours, would it not?—No, theirs would cost rather more.

How much—4*d.* an ounce?—I could not say.

5*d.*?—I could not say.

Let us be lavish about it and say 8*d.*

Mr. ELDON BANKES: He says he cannot say.

Mr. DUKE: He is going to say when he has worked it out.—There is hyponitrous acid in Oppenheimer's—you will see it is mentioned there—and that would be specially prepared.

"Hyponitrous acid gas to saturation." Do you think it is just possible that Dr. Tucker introduced a solution of hyponitrous acid gas to saturation?—No.

Why not?—Because I found none.

But you found some nitric compound, did you not?—Some nitrite.

You found nitrite preparations, but not the solution of hyponitrous acid gas to saturation?—No, I did not find that.

Is that a costly commodity? How much does it cost by the pound, for instance?—It is not priced in any list. It is rather a rare preparation, and it would take some time to prepare, so it would be impossible to tell you what would be the exact cost of it.

Mr. Justice RIDLEY: Do you think that the bottle of Neboline is as likely in your opinion to be a cure as the other one; *do you think it is as good a preparation as the other?*—No, I do not think it would be.

Mr. DUKE: *Which is the one which is not as good as the other?* You think that Oppenheimer's is not likely to be as *as good a preparation as* Dr. Tucker's?—It is not the same preparation as Dr. Tucker's.

And so far as you can judge it is not as likely to be effective?—I do not think it would be.

But even Oppenheimer's is recommended by them as practically a specific for asthma, and you will agree with me, will you not, that what they say is, that it is similar in every respect to Dr. Tucker's—that is what they say in effect?

Mr. Justice RIDLEY: Is it a doctor's prescription?—No, it is a wholesale chemist's.

Mr. DUKE: Dr. Tucker's is a doctor's prescription.

Mr. ELDON BANKES: Is that so?

Mr. DUKE: Mr. Tucker was in the box yesterday and told you who his brother was, and that he is a well-known physician.

Mr. ELDON BANKES: He invented it.

Mr. DUKE: He prescribed it; he compounded it.

Mr. ELDON BANKES: Yes, he compounded it.

Mr. DUKE: It is the prescription of an American doctor.

Mr. Justice RIDLEY: There is no difference.

Mr. DUKE (to the witness): There are good doctors in the United States, are there not?—Certainly.

And apparently one of them has contrived to hit the thing for curing asthma with a specific which you say can be produced more cheaply than Oppenheimer's?—Yes.

Mr. Justice RIDLEY: *Do you know any specific for asthma?*—There is no actual cure for it, so far as I know.

That does not answer the question. Do you know anything which produces the same effects on asthma as have been proved to have resulted from the use of this specific?—Certainly.

Mr. Justice RIDLEY: *I should like to know what it is.*

Mr. DUKE: Perhaps you mean datura or stramonium. I think I saw a person smoking a cigarette of datura or stramonium?—There are many drugs which will relieve asthma.

Are they not all temporary in their action?—Yes.

And do not they lose their effect after repeated recurrence of asthma?—Not necessarily.

But do they not frequently? Are they not frequently kinds of things which lose their effect?—Sometimes they do.

And do not many of them, if not all of them, cause very great discomfort and physical damage to the patient by interference with his lungs?—No, certainly not.

For instance, the inhalation of smoky vapour. Is not that much more likely to hurt the patient than the inhalation of the vapour which is produced here?—The inhalation of smoky vapour is injurious to some people.

Seriously injurious?—It produces bad effects in many people; it has done.

And do doctors go on prescribing that kind of treatment nevertheless because asthma is such a terrible ailment?—Doctors are careful as regards prescribing these smoke medicines. If a doctor found that it did not suit the patient he would adopt some other form of treatment.

Did you hear the evidence of the numerous witnesses who came here for the plaintiff this morning and said, "We had been treated for years by medical men and they failed to relieve our asthma"; did you hear that?—Yes, I heard that.

Is that not common experience with regard to the treatment of asthma?—Is what common experience?

Is it not common experince that you find an entire failure to relieve the patient from the liability to constant paroxysms of asthma?—No.

Do you mean that the doctor usually does produce such effects as have been spoken to here this morning?—Certainly.

He does?—Yes.

Then these are unfortunate instances where the doctors failed?—I should say that these cases, many of them, had not been thoroughly treated by a doctor. They may have consulted a doctor once or twice, but I should say they had not been under a thorough course of treatment.

name and address of the purchaser, the name and quantity of the article, the purpose for which it was wanted, attested by signature, and it must also have the label "Poison." So you will see how careful the legislature is in safeguarding the public generally from the sale of these particular things which I shall show you in a moment are contained in this specific of Mr. Tucker's from indiscriminate sale. That fact would be known, and is known, to the medical profession generally, and, indeed, to most persons, and there is this further fact known to the medical profession, because we have heard now from the plaintiff's own witnesses that it was generally known in the medical profession, at any rate by the year 1903, that this particular specific contained cocaine. Now, gentlemen, you will bear in mind the circumstances under which this article was written to which I will have to call attention in a moment, and the fact that the specific was sold without regard to any of these precautions, and, indeed, without any of these precautions; and, on the contrary, it had upon it what, as was pointed out by the coroner, and, no doubt, you will understand, is often understood by the common people as being a mark of genuineness and authenticity—it had the Government shilling stamp. Now, what was the composition of the liquid which was sold in this way by Mr. Tucker? We have had it analysed and we find by analysis that the ounces which you may buy do not always contain the same quantity of ingredients, apparently. If that is so it would indicate that there is not very great care taken in the preparation of it by the people who are responsible for the preparation, because our analyses vary to this extent; take cocaine for instance; one sample which was analysed was found to contain about a grain and a half, or thereabouts, of cocaine, per ounce, but another sample which we analysed contained about 2·28 grains, or thereabouts—a considerable quantity in excess of what there was in the first sample; and it undoubtedly does contain in considerable quantities cocaine and atropine and sodium nitrite. Now sodium nitrite is not a poison. Cocaine and atropine are, but the combination of these sold indiscriminately in this way will be proved before you to be, in the opinion of men standing as high in their profession as anyone can possibly do, to use their own words, a serious danger to the public. Now, why is that so?

Mr. Justice RIDLEY: That is not what you said in the libel.

Mr. ELDON BANKES: Yes, my lord.

Mr. Justice RIDLEY: It is not, Mr. Bankes.

Mr. ELDON BANKES: What the libel says is that it is a fraud upon the public.

Mr. Justice RIDLEY: Yes; but that is not the same thing.

Mr. ELDON BANKES: That is a question for the jury.

Mr. Justice RIDLEY: If you charge a man with fraud you must prove that he is guilty of it. That is not a question of public interest at all, but it is a question of which you must prove the truth.

Mr. ELDON BANKES: Of course, my case to the jury is this——

Mr. Justice RIDLEY: I have not any doubt at all about it that if you charge a man with fraud you must prove that he is guilty of it, or you are guilty of libel.

Mr. ELDON BANKES: It depends what your lordship means by "fraud."

Mr. Justice RIDLEY: Dishonesty.

Mr. ELDON BANKES: I submit I am entitled to say of this system under which this specific is sold that it is a fraud upon the public.

Mr. Justice RIDLEY: That is not what you have said.

Mr. ELDON BANKES: It is a question for the jury.

Mr. Justice RIDLEY: You have charged him with fraud.

Mr. ELDON BANKES: It is a question for the jury, surely, as to the meaning of the libel.

Mr. Justice RIDLEY: I agree; but it seems too plain that that is what you have said, or I should not have put it so.

Mr. ELDON BANKES: I am sure your lordship will not prejudge the question.

Mr. Justice RIDLEY: It is hopeless. You have not said that this is a serious danger to the public. Where are the words in the libel which say that?

Mr. ELDON BANKES: I am commenting upon a certain state of things. One of the things upon which I am commenting is that this specific, containing these drugs in dangerous quantities, is being sold indiscriminately; that is the first thing. I say that it has been sold indiscriminately without any warning as to its character and with an encouragement to use it to any extent.

Mr. Justice RIDLEY: That is not what you have said in the libel.

Mr. ELDON BANKES: Those are the facts upon which I am commenting, and I respectfully submit to your lordship that I am entitled——

Mr. Justice RIDLEY: I must ask the jury what they think about the meaning of the libel.

Mr. ELDON BANKES: I am obliged to your lordship.

Mr. Justice RIDLEY: I have great difficulty in the case, as I have told you, from the outset. You have not said that, but you have something much worse. You charge him with fraud and give the reasons. There is the price of the article.

Mr. ELDON BANKES: Gentlemen of the jury, I am sure you will realise that the question ultimately is a question for you. Undoubtedly the word "fraud" has been used. It is a word which has many meanings, and it is a question for you as to the meaning in which it was used in this particular article. I suggest to you that this particular article, or note, or whatever you call it, uses the word in this sense: the writer is saying that this specific is a fraud upon the public; the circumstances under which it is sold, the nature of the specific, the way in which it is advertised, what is said about it—all those are material matters for you to consider when you are asking yourselves whether this word "fraud" in that connexion is a word which may legitimately be used by persons who formed a very strong opinion upon the subject.

Mr. Justice RIDLEY: You must prove it is true.

Mr. ELDON BANKES: I have an authority about that.

Mr. Justice RIDLEY: So have I, and I am speaking from it.

Mr. ELDON BANKES: Of course. I will discuss it with your lordship now if your lordship wishes it.

Mr. Justice RIDLEY: When you choose to. My view is that if you choose to charge a man with such an offence as fraud it is an attack upon his character, which is not a matter of public interest and which you must justify.

Mr. ELDON BANKES: Of course, if your lordship rules that there is no justification, there is an end of the case.

Mr. Justice RIDLEY: That is what I think.

Mr. ELDON BANKES: If your lordship takes it upon yourself to rule it now I have nothing more to say.

Mr. Justice RIDLEY: I should like to hear your argument about it, because that is my view of the law.

Mr. ELDON BANKES: Does your lordship wish me to argue it now?

Mr. Justice RIDLEY: If it comes to that, I do. I should like to know how you put it. I have understood that to be so for a long time. I see your junior in a book which he has written—a very able book—suggests that to be the fact, and I think I have an authority to that effect.

Mr. ELDON BANKES: I should like to refer your lordship to an authority if you wish to hear me now.

Mr. Justice RIDLEY: If you wish to deal with it now, do.

Mr. ELDON BANKES: I rather understood that your lordship wished me to do so now.

Mr. Justice RIDLEY: I am rather subject to you. You may wish to bring a body of evidence here to justify, not the truth of the matter, but to prove that it was a matter of public interest.

Mr. ELDON BANKES: Yes, my lord.

Mr. Justice RIDLEY: And that I conceive to be the fact; it is a matter of public interest if you deal with the general question relating to the sale of specifics which contain poisons.

Mr. ELDON BANKES: Yes, my lord.

Mr. Justice RIDLEY: But the thing is as to the character of the person who has done it in this case.

Mr. ELDON BANKES: I say nothing about the man's character.

Mr. Justice RIDLEY: Then if you have attacked his character by charging him with fraud he is entitled to say: "I am not fraudulent and you must justify it."

Mr. ELDON BANKES: It is a question as to what the libel means.

Mr. Justice RIDLEY: Yes.

Mr. ELDON BANKES: It is ultimately for the jury to decide.

Mr. Justice RIDLEY: I think I shall have to leave it to the jury.

Mr. ELDON BANKES: If your lordship pleases; and then perhaps it will be convenient for me to say what I have to say to them now.

Mr. Justice RIDLEY: I do not wish to stop you, but at the same time I had better warn you that my present mind is breathed out through the mouth necessarily?—I do not think one can say that.

Did you see Mr. Tucker operating the thing yesterday?—A considerable part of it would be breathed out.

There could not be any absorption of cocaine into the system from what was breathed out, could there?—No.

There could not be any absorption except from the particles which were in contact with the lining of the inner surface of the lung?—Yes; there would be absorption there.

There would be some absorption there, but the effect of the absorption would wear off almost immediately?—A minute quantity of the drug would be absorbed into the circulation and would be carried round in that way.

It would be discharged out of the system?—Not for some little time.

What do you call some little time—a day?—Probably about a day.

And the gentleman who spoke this morning may have been one day getting rid of such portion as he retained of 1/2000th part of a grain of cocaine which he had inhaled into his lungs and of which he had breathed out part?—I think that figure is hardly correct, is it?

Put it right; give me some other.—You said in ten squeezes—that is one inspiration—there is 1/2000th part of a grain?

Yes. But I understand there would be a great many inhalations of the vapour during the day.

You think there might be more during the day—that the patient might not be better after the first. We cannot get it mathematically accurate?—From what I have heard the patients had several inspirations.

They are recommended to have four?—Yes.

Mr. ELDON BANKES: No.

Mr. DUKE: Yes, four times a day.

The WITNESS: Four or five times this process is to be gone through, but each time there would be several of these ten squeezes.

Do you think it is correct to say that a man might ultimately get 1/2000th part of a grain of cocaine into his system to be discharged by the ordinary natural processes?—I think he would get a good deal more than that.

What is the standard dose of cocaine which is mentioned in Squire's Pharmacopœia?—One-sixth to half a grain, or one-twentieth to half a grain.

Are you sure about that?—I think that is so.

Are you sure it is not a good deal more?—It is one-twentieth to half a grain—the official dose.

At what intervals?—That would be one dose.

How often a day is it given, do you know?—It might be given two or three times a day.

So that a man might get a grain and a half in the course of a day?—No; that would be a dangerous dose to give. The maximum dose is not the dose which is usually given.

He might get a grain of cocaine in a day?—A man might if he would take it, but it does not follow that it would be a safe dose.

I did not ask you that, but I want to see what is done in the profession. How is that cocaine administered?—It may be administered by the mouth.

Into the stomach?—Yes.

So that that is sure to circulate through the system?

Mr. Justice RIDLEY: In a liquid form or how?—It would be dissolved in water.

In some water by itself?—Yes.

Mr. DUKE: What is the largest quantity you have known administered in a day without hurt?—Of cocaine?

Yes.—It is a drug which is hardly ever given by the mouth in my experience—very rarely given indeed.

What is the largest quantity you have known given in a day? I do not mean in your own personal practice, but known as a matter of scientific knowledge?—It is a drug which is given very little by the mouth, and I could not tell you the largest quantity which I recollect. I have known of so few instances where it has been by the mouth.

I quite accept what you say. You are telling us of what the practice of other people is with regard to administration by the mouth?—Yes; it is hardly ever given.

You spoke of the impropriety of administering cocaine in cases of heart disease?—Yes.

And in cases of long-standing consumption, did you not?—Yes, advanced consumption.

And in any other cases?—Kidney disease; and bronchitis I think was the other one.

Is that because cocaine would aggravate the malady?—It is because when the heart is weak and feeble any drug which has a depressing action on it may be most dangerous; and I consider that even a minute quantity of cocaine would be dangerous in some forms of heart disease.

1/10,000th part of a grain?—I think you are rather underestimating the quantity which would be taken. It would probably be rather more than that. One might say that if a drop of the stuff were taken that would contain 1/2000th part of a grain, and that would correspond to 100 compressions.

A drop of the stuff requires 100 shots from that atomiser?—Yes.

And of that 100 the greater part of the vapour produced will be breathed out through the mouth; it will not remain in the lungs at all?—A certain part of it will.

Obviously the greater part, necessarily. You do not suggest that a man is going to hold his breath until this vapour has disappeared into his system, and there is a vacuum in the lung; you do not suggest that?—No.

He must breathe it out, must he not?—He must breathe out part of it.

If he did not promptly breathe it out, if the vapour was absorbed, a vacuum would occur in the lungs?—Yes; a considerable part would be breathed out.

All these figures are necessarily speculative, are they not?—Certainly; you can get no exact amount; but with one drop there would be 1/200th part of a grain of cocaine and one might take 1/500th part of a grain as being the amount retained. That would be in 100 compressions—1/500th part of a grain of cocaine.

1/500th part of a grain of cocaine might be retained out of 100 compressions by a person who thought he had asthma, and in fact had heart disease?—Possibly, yes.

Do you find that the case is frequent of people who suppose they have been suffering for years from asthma, but, in fact, have been suffering all the time from heart disease?—I find they are quite common.

That a man suppose he has been suffering for years from asthma, and, in fact, his trouble has been heart disease?—Heart disease, or one of those conditions which I have mentioned.

Or kidney disease?—Yes.

Or advanced consumption?—No, not advanced consumption, of course, because death would occur.

Heart disease or kidney disease?—Yes, or emphysema.

Has his doctor shared the mistake with him during those years?—No.

How are you able to tell us that the man had suffered for years from kidney disease, and was under the delusion that it was asthma?—Because I have seen a great many patients—hospital out-patients, who come up and tell me: "I have got asthma," and I find they have not got asthma, but they have got one of these condition which I have mentioned.

I will take the case of one of those patients. Suppose one of those patients had the use for a week of one of these inhalers, and tried it upon himself, would the specific relieve his symptoms or not?—I do not think it would have any effect at all in relieving his symptoms.

Do you suppose that a man who has had the use for a week or fortnight of a thing which did not relieve his symptoms is then going to buy it for £3?—No.

Is there any other ailment except asthma which this specific, so far as you are aware, does relieve?—I should say that it would probably relieve some conditions such as hay fever.

Any others?—And catarrhal conditions it might relieve.

Those would be asthma and conditions analogous to asthmatic conditions?—It might relieve them.

But asthma is the ailment which it unquestionably does relieve, is it not?—In many cases no doubt it does.

That being so, as far as you have heard in the course of this trial, what is there upon which you would say that the plaintiff here has been fraudulent in selling this specific as a remedy for asthma?—I could not express an opinion.

Is there anything, or is there nothing?—I could not express an opinion about it.

I am going to press you a little. You have been here during this trial?—Yes.

Is there anything you have heard in the course of this trial upon which, as far as you are concerned, you would say that the plaintiff was fraudulent in selling this specific as a remedy for asthma?

Mr. ELDON BANKES: I submit that is a question for the jury, and not what this witness's particular opinion may be;

that they receive that they will send him the money and he will be in the same position, practically, as if he had received it at first. It is quite true that they have that opportunity of testing it, but Mr. Tucker gave them the opportunity of testing it because he is satisfied that the drug is so potent and so powerful that it is bound to give them such relief that they are certain to send their money; but he does not take any steps to satisfy himself that the specific so sent, though it gives temporary relief, will not do the man ultimately considerable injury. I say when you find these sums charged under those circumstances it is a legitimate ground for using strong language with regard to such a system. You have heard the details of the differences in price and you have probably formed your own opinion about them. You have heard the amount which he receives annually for the sale of this specific. You know what his expenses come to, and I shall probably have afterwards to say a word to you about them. But I want you to bear in mind what our point is with regard to that. It is not merely the fact that what may seem to be an exorbitant price is charged, but the circumstances under which it is charged—that it is asked of a man who has been given no opportunity of being examined, no opportunity of being told whether it is likely to do him permanent good or permanent harm. Mr. Tucker, you know, when he sends this out, goes, as I suggest to you, a great deal further than the case justifies, and a great deal further than he himself now is willing to justify. I ask you to look at these things and to say that when he sends these out with this specific for the fortnight's cure he is content to rely upon the fact that he thinks the patient will get immediate relief; but he does represent to the patient that not only will he get immediate relief, but the stuff, if he uses it, will cure him. Now what justification is there for that? He has sought to draw the distinction, and he says "I mean by 'cure' that it will relieve the attack from which you are suffering at the moment, but I cannot and do not suggest that it will prevent it ever coming on again." If you read these instructions you will see that he draws the distinction between relief and cure. Let me read one passage. He says: "You will notice by the above instructions that it is necessary for the vapour to reach the lungs in order to arrest the attacks, heal the mucous surfaces, and cure the disease." This is part of the system under which this specific is sold, and I ask you again, What do you say of a man who comes here and tells you that he does not profess to cure and that the stuff will not cure, but the stuff will relieve and because the attacks are relieved the patient's general health will improve, but that he does not profess to cure asthma? And what do you say of the system under which it goes out on trial, and the patient, who undoubtedly will receive immediate relief, is told here distinctly and definitely "And what is more, if you buy this it will cure you." And, gentlemen, it does not end there, because there is another expression in these instructions to which I will ask your special attention. What is meant by this statement to the patient: "If you are in the habit of using alcoholic stimulants, morphine, opium, or other narcotics, abandon their use." Is it not to indicate to persons receiving this specific that such things are not given to asthmatics, and that if he will take this in substitution it will benefit him? What do you think of a person doing that if in fact the stuff contains, not alcoholic stimulants, morphine, opium, or other narcotics, but it contains cocaine and atropine? What can be said for a system part of the machinery of which is the use of this thing to induce patients to believe, not only the broad statement that it will not harm them, but the statement that "these obnoxious things are bad for asthmatics, give them up, take my treatment instead"; whereas in fact you find that there are more powerful and potent poisons in his mixture than these the use of which he says is to be avoided. There is another point I want to mention, and I will ask you to bear it in mind. What is meant by that list of questions which is sent out with the specific? What is the object of that? Is the object of that to lead the patient to think that he is in connexion with some qualified medical practitioner who will be able to judge from these answers whether his case is a fit one for this treatment? Is that the object? What other object can there be? You will remember I put to him question after question, and I said, "What do you want to know that for; what good is it to you?" and his answer was "It is my brother's question." I said to him, "Were they not framed by your brother, who is a doctor, in order that on receipt of the answers he might judge whether the specific was one proper to be sent to that patient or not?" and he had to admit it. Then why is it sent out from this villa at Herne Hill by people no one of whom possesses any medical knowledge at all, except for the purpose of inducing the patient to believe that he is dealing with a person who can judge by those answers as to whether the specific is one suited to his case?

Now, gentlemen, those are matters entirely for you. I want you to pay the attention to my evidence which you have so kindly paid to the evidence of the other side, and I can tell you shortly what it consists of. I first of all shall call evidence to prove the analyses of this liquid in order that you may be in possession of the information as to what it contains. I then shall call, gentlemen, a large body of medical evidence, persons about whom it cannot be suggested that they come here from any indirect motive of benefiting the medical profession. I hesitate to give you their names because of course I am not always sure that at the moment I can get persons in this position to come here at the time when their evidence will be wanted; but I feel sure that I shall be able to bring before you persons in the position of Sir Douglas Powell, and Sir Lauder Brunton, and Mr. Tilley, and many others who are at the head of the various branches of their profession, and who will tell you in substance this—that in their opinion the sending out of this specific indiscriminately, containing cocaine as it does, is a danger to the public, because cocaine is an extremely insidious drug, and some people are extraordinarily susceptible to it, and that its use under these conditions in their opinion is likely to produce danger to the public. They will say that in their opinion the quantities, although small, sprayed in this way are sufficient in certain people to produce this cocaine habit. I shall also call one gentleman particularly who has had under his treatment a number of persons who have suffered through the Tucker treatment.

Mr. SMITH: I do not want to take any objection, but if my friend is going into this in detail I should ask him to reserve it until I can take a formal objection to the evidence. If my friend states to the jury the effect of it now the point of the objection has gone, but I mean at the proper time to object to this evidence.

Mr. ELDON BANKES: I want to fight this case perfectly fairly, and therefore I will not go into any detail about it, but, in order to explain this to you and to prevent any misconception which you may be under, this witness will tell you—I am not going into details—that these people are suffering from what he calls the Tucker habit, and he will explain to you exactly what it is, and the effect upon the patient. It is not perhaps quite accurate to call it the cocaine habit, but it is a form of the cocaine habit, and I think he calls it the Tucker habit. He will tell you the difference, if there is any difference, between the two. I want to make that plain because possibly I may have not made the matter quite plain myself before because I did not quite understand what the distinction was.

With those few preliminary observations I will now call my evidence. I have not addressed you, possibly, on some points upon which I ought to have, because, as I have told you, I am most anxious to call certain gentlemen this afternoon in order that they may be liberated, because I know their time is very valuable.

CLARENCE ARTHUR SYMMONS, *examined by* Mr. FRASER.—I think you are a clerk in the employment of the defendant's solicitors, Messrs. Potter, Sandford and Kilvington?—I am.

Did you in pursuance of instructions from your principals go to Mr. Tucker's house in Herne Hill in July, 1907?—Yes, I did.

On the 8th July, I think it was?—Yes, the 8th July.

I think you saw the plaintiff, Mr. A. Q. Tucker?—I did, yes.

What did you ask for?—I asked for two ounces of Dr. Tucker's specific, and he gave me a two-ounce bottle, but I said I would prefer two separate ounce bottles, so he took that back and gave me the two separate ounce bottles, and I gave him the 16s. and came back.

I want you to look at the bottles, please. (Bottle handed to the witness.)—That is one of them.

It was sealed up, was it?—Yes, just like this, without the label on it, with a shilling stamp over it.

Now look at the other one, please. (Handing bottle to the witness.)

Mr. SMITH: Is there any difference?

Mr. ELDON BANKES: There is no difference; it is merely to identify them.—Yes, that is the other one.

Mr. FRASER: These are the two?—Yes.

Mr. Justice Ridley: You will have to get to that point at last.

Mr. Eldon Bankes: I do not in the least desire to argue it. It is very difficult to argue the case and take the evidence at the same time.

Mr. Justice Ridley: I know; but this evidence is quite useless, if my view of the case is correct. We shall be here for I do not know how long, if my view of the law is correct.

Mr. Eldon Bankes: I am sure your lordship will bear with me; we are before the jury.

Mr. Justice Ridley: Yes, but you see this evidence does not help me.

Mr. Eldon Bankes: We are only now on re-examination upon evidence which has already been given.

You were asked some questions yesterday about Mr. Oppenheimer's specific.—Yes.

Would your opinion about that specific be the same as your opinion with regard to Mr. Tucker's specific if it was used indiscriminately in the same way?—Yes.

Mr. Justice Ridley: Are you aware that it says on the bottle that it is perfectly safe to use it?—That implies that it is being used under medical supervision, I take it.

Not at all. "In compliance with the Sale of Poisons Act this preparation is labelled poison, but, nevertheless, it is perfectly safe if inhaled by means of the aeriser or vaporiser."

Mr. Eldon Bankes: Your lordship will also see it is accompanied by a statement in the list which I have not got a copy of.

Mr. Justice Ridley: "To be used as directed by the physician." Yes, but it says it is perfectly safe.

The Witness: I do not think that is sold except to physicians; I do not think one of the public can buy it.

Mr. Justice Ridley: I do not know. Your observation made me put this to you. I know it is sold with a safe label on it, and that is all I know.

Mr. Eldon Bankes: My friend Mr. Duke read this out from the list yesterday: "There is a further statement that this specific can be purchased wholesale by the profession from Messrs. Oppenheimer."

Mr. Justice Ridley: This direction is made for the person who uses it, is not it?

The Witness: But the doctor would buy it.

Mr. Justice Ridley: "It is perfectly safe if inhaled by means of the aeriser or vaporiser."

Mr. Eldon Bankes: And under the physician's direction.

Mr. Justice Ridley: That is on the other side of the bottle.

Mr. Eldon Bankes: But it is on the bottle.

Mr. Justice Ridley: But independently of the physician it says it is safe.

Mr. Eldon Bankes: That is Oppenheimer's view.

Nevertheless, is that Oppenheimer safe if used indiscriminately?—No, certainly it is not.

So your observation would apply equally to Oppenheimer, although they put that there, if it were used indiscriminately and not under the physician's directions?—Certainly.

You were asked the question yesterday by my friend, Mr. Duke, about the official dose of cocaine?—Yes.

You said, I think, that was one-twentieth to half a grain. Does the fact that that is given as the official dose indicate that it may be safely used in cases, for instance, of heart disease?—No, the official dose implies that it is being given for a proper purpose under medical supervision. Cocaine would be a dangerous drug to give in any dose in a case of heart disease.

That is merely the official dose for the administration of the drug in a proper case?—Yes.

In spite of the questions which were asked you yesterday by Mr. Duke, what is your opinion as to whether sufficient cocaine could be absorbed by the continued use of the Tucker stomiser to cause injurious effects upon persons suffering from heart disease, or kidney disease, for instance?—I am quite certain that sufficient could be absorbed in those cases to cause serious affections.

Mr. Justice Ridley? I have had all this before.

Mr. Eldon Bankes: With reference to persons suffering from heart disease getting relief from the use of the specific you were asked yesterday if a person were suffering from heart disease and if he were suffering from asthma and sent for this specific and used it would it give him relief?—Yes.

You answered that it would not give him relief.—It would not give him relief in pure heart disease or pure kidney disease, but if the heart disease or kidney disease were complicated with asthma or bronchial catarrh then it would give temporary relief; but the effect of the drug, if continued for some days, would be very injurious to the heart.

Mr. Justice Ridley: We had better understand about this Oppenheimer bottle. It has got on the neck "Poison; not to be swallowed; must only be used with the aeriser or vaporiser"; then in the front "to be used as directed by the physician," and on the side, "in compliance with the Sale of Poisons Act this preparation is labelled poison, but nevertheless is perfectly safe if inhaled by means of the aeriser or vaporiser." That is what it states on here.

Herbert Tilley, *examined by* Mr. Eldon Bankes.—I think you are a Fellow of the Royal College of Surgeons of England?—Yes.

You are surgeon to the Ear and Throat department of the University College Hospital of London, surgeon for diseases of the nose and throat of King Edward VII. Hospital and formerly surgeon for Golden-square Throat Hospital?—Yes.

Have you for some time been familiar with this Tucker's specific?—Yes, as used by patients.

Have you had the opportunity of observing the effect of it upon patients who have come to you?—Yes.

You have been made acquainted, I think, with the result of the analysis of this liquid?—Yes, I heard it yesterday afternoon.

You are aware that it contains, amongst other things, cocaine and atropine?—Yes.

Are you familiar with the nature and effect of those drugs?—Yes, particularly with cocaine.

Is it a drug which is used in medical practice?—Yes.

Is it a drug the use of which is dangerous?—Yes, without particular care.

Will you give your reason for that statement?—Cocaine is one of those drugs which has a very potent effect upon the region to which it is applied, when it is applied locally, or on the constitution when it is either absorbed or taken in some form of liquid or injection. There is no means of knowing before it is used, either by the local application or by its injection, whether that particular patient possesses what is known as an idiosyncrasy to the drug. An almost fractional amount in one case will produce very alarming symptoms, and in another case it may have no particular effect; but you cannot by any means tell before you administer whether the individual case will stand it or not, and therefore you must commence with very small doses, and you must watch its action as you go.

You say it may be followed by alarming results?—Yes.

How does the drug act to produce those results?—Supposing the patient is affected by it? You mean to say we will assume the patient cannot stand cocaine?

Yes?—And he has given to him what to him is an overdose?

Yes?—In the course of about three to five minutes he would probably say: "I begin to feel so curious; I feel faint; my heart is beating very fast." You notice he is getting pale and getting a cold perspiration on him, and becoming what we should term anxious; that is to say, he is in a very uncomfortable mental and physical condition. That is what you might call a mild case of acute poisoning.

Are some patients more susceptible to cocaine than others?—Yes, curiously so.

Are there certain cases of diseases in which it is extremely dangerous to use cocaine, for instance heart disease?—I should say yes, but my experience in practice does not deal much with heart disease and therefore I could not speak with the same authority in that respect that I possibly might in others.

In your opinion is it safe to use cocaine indiscriminately?—Certainly not.

And does that answer apply even though the doses may be extremely small?—Yes, because the dose, however small, may be a large dose for the individual who uses it.

Are you familiar with the instructions which Dr. Tucker sends out with the specific?—I read them.

Do you think that those instructions are likely to lead to the continued use of this specific?—Yes.

What is the effect of cocaine? Is its action cumulative or not?—I should say that its effect is cumulative rather than its action; there is a distinction there.

Is the use of this specific, in your opinion, likely to be injurious to patients, or to some patients, if they continue its use for a *considerable time*?—Yes.

Have you yourself noticed the effect of the use of this specific upon patients who come to you?—Speaking generally, yes.

Mr. Justice Ridley: I have got all that before.

Mr. Justice RIDLEY: There is not any spray.

Mr. DUKE: I suggested that the witness should describe what he means.

Mr. ELDON BANKES: The vapour; we mean the same thing.

Mr. Justice RIDLEY: The spray would not come into contact with the bronchial tubes according to the evidence before me. I have not got evidence of any spray which could possibly get there. I am only dealing with the evidence.

Mr. ELDON BANKES: Is your lordship referring to the difference between vapour and spray?

Mr. Justice RIDLEY: Yes, I think you had better use the word vapour.

The WITNESS: I do not think "vapour" is a correct scientific term. A vapour is invisible and does not contain solid particles. Call it a fine spray.

If you do not object I shall call it vapour, because I shall know what I mean?—Yes, but scientifically a fine spray would be the more correct term.

I would rather say vapour if I may, because I shall be able to keep my notes of this case correct, but I quite understand what you mean. What would happen to the vapour?—The vapour would come into contact with the bronchial tubes and the spasm of them would be relieved by the atropine and cocaine present, and also the nitrite of soda would assist that action.

Mr. ELDON BANKES: In what way would they act?—By deadening the sensibility. The cocaine would act in that way and the atropine would also act in a similar way.

So that by the use of the drugs in this way you would expect to get immediate relief from a paroxysm of asthma?—Yes, I should expect it.

That would be the natural result of using these powerful drugs?—I should expect in true asthma that the spasm would be relieved and relief would be given in many cases.

In your opinion, as a concluding question, is it safe to distribute this specific in the way in which it is distributed?—No, I do not think it is.

Mr. Justice RIDLEY: That is not the point at all.

Cross-examined by Mr. DUKE.—Do you think it is fraudulent to distribute it?—I should not like to express an opinion.

You would want to know first whether it was honestly distributed, would you not, or whether anybody was intentionally deceived about it?—I should prefer not to express an opinion.

You are here with your opinions about this matter.

Mr. Justice RIDLEY: Is there any fraud in this matter?

Mr. DUKE: Suppose I had a bottle of this specific and an atomiser and an asthmatic friend whom the members of your profession had totally failed to relieve, and I handed it to him and said: "Look here, I have heard during two or three days evidence which satisfies me that this will do you good"; would you say I was guilty of a fraud upon him because there was cocaine and atropine in it?—No, I should not say you would be guilty of a fraud.

It would be most unjust to say so, would it not?—I should say it would be unjust.

And if that is what the defendants in this action substantially have done about Mr. Tucker, what do you think of that; is it just or unjust? Perhaps you would rather not express an opinion?—I do not think that that is an opinion which I ought to express.

If you tell me that you would rather not, I will not press it.

Mr. Justice RIDLEY: Very well, leave it.

Mr. DUKE: I am going to ask you about two or three of these things which you have been giving us evidence about. You have made an analysis?—Yes.

Are you in general practice as a medical man?—Yes, a consulting practice.

Mr. Justice RIDLEY: What is the rest of it? Will you ask him; we have got three grains at present.

Mr. DUKE: I was going to ask him that.

You have three grains out of what quantity?—A fluid ounce.

Three grains out of 440?—Yes.

What are the other 437 grains?

Mr. Justice RIDLEY: We have nitrite of soda.

Mr. DUKE: Yes, there is nitrite of soda, too. Cocaine was 2·28 grains and atropine 1·57.—The atropine was 0·67.

What was the nitrite of soda?—15·25.

Were there any other specific ingredients?—Glycerine. Then there was some oily matter.

Do you know what it was?—I think that that arose from some balsam which was put in.

Do you know?—Yes.

You are sure?—Yes.

It was oily matter which arose from balsam; what quantity was there of that?—0·67 grain; benzoic acid, 0·49 grain; then there was a trace of silica, 0·24 grain; oxide of magnesium, 0·11 grain; the glycerine I have mentioned, and the rest was water.

How much glycerine?—20 to 30 per cent. by volume.

Mr. Justice RIDLEY: Not per grain you mean?—No, by volume.

Mr. DUKE: About 20 or 30 grains possibly would be glycerine?—No, more than 20 or 30.

Because the specific gravity would be different?—20 or 30 per cent.

I did not follow that; that is about one-fourth?—About one-fourth.

Do you think you could make this preparation?—I think so.

Have you any confidence in being able to make it? You have given your analysis. Have you any confidence that you could make it?—I think that I could make a preparation which would have the same action.

But are you sure that you could make this preparation?—I do not say that it would be absolutely identical, but it would have the same physiological effect.

Why is it that you cannot be sure that you could make a preparation identical with this in its constituents?—The colouring matter might be different and certain details.

I will leave out colouring matters. What are the other matters besides colouring matter?—If I had the same colouring matter and the same ingredients as in the analysis the preparation would be almost exactly the same.

Are you always able to ascertain vegetable oils with certainty in analysis?—When there are small quantities present one cannot——

Cannot with certainty say what they are?—Cannot with certainty say exactly what they are.

Do you think that there may be in this composition some small quantity of vegetable oils which you cannot with certainty identify?—I do not think the vegetable oils would have any definite effect.

Perhaps you would not mind going back and answering my question now. Do you think there may be in this specific some vegetable oils in small quantities which you cannot with certainty identify?—You can detect them as vegetable oils.

But you cannot with certainty say what they are?—I could not say what they are.

That is what I call identifying them. You think that may be so?—There are some there, yes. I said so—oily matter.

That is what you call oily matter?—Yes.

That is rather an uncomplimentary sort of description of it; it does not prepossess you with it, does it? It is just possible that the inventor of this specific might attach a good deal of importance to what you call the oily matter?—I tasted this oily matter and examined it; it seemed to be quite inert.

I did not ask you that. It was put there on purpose evidently, was it not?—Yes, possibly.

And it is conceivable that the inventor of this specific may have supposed, rightly or wrongly, that it was an important ingredient in the specific?—It may have been supposed so.

Mr. DUKE: Your lordship identified a bottle this morning.

Mr. Justice RIDLEY: Yes, I put the figure 1 on it. (Same handed to the witness.)

Mr. DUKE: Just look at that and see if you recognise it.

Mr. Justice RIDLEY: When was that put in, I have forgotten?

Mr. DUKE: It was produced by one of the witnesses who said he had tried a specific which he had obtained in the Tucker atomiser, but it was ineffective for the cure of asthma.

Is that a preparation of a well-known firm of wholesale druggists?—Yes.

Oppenheimer, Son, and Co., Limited?—Yes.

Are the ingredients practically the ingredients which you say this preparation of the Tucker specific contains?—I do not see the ingredients on the bottle.

Are they not stated there?—No.

Do you know Oppenheimer's list?—I have seen it.

Just look at that and see if it is Oppenheimer's list which is in general use among people who deal in drugs and see if the last witness? You have indicated you do not entirely agree with him.—My view is this: I believe the evidence, so far as it went yesterday afternoon, was to this effect, that the amount that came out of the spray by the ordinary spray was infinitesimal, and could that amount be deleterious. I think that is your point, really.

You shall tell me, and I will accept it from you: Is your view that an infinitesimal quantity could be deleterious?—The amount that comes out of this spray I think is deleterious if continued. Of course, once used it has a passing effect and will produce no harm, but the continued use will certainly produce harm, in my opinion.

I would rather deal with the specific case and not generalities. You heard the specific evidence given by the last witness. I only want to know whether you will agree with it or whether there is any point you wish to make clear?—If you will ask me the specific points I will answer them.

I thought perhaps it would conduce to brevity if you could state, after listening to his evidence, whether there was any specific point you wished to dissent from?—I think if you just put to me one or two points I would prefer to answer them.

You agree as regards the number of grains of cocaine per fluid ounce?—Yes.

You accept all that?—I accept the analysis yesterday.

You would accept the statement that it would take about 100 compressions to exhaust a drop of the specific?—I think that has been ascertained; I do not mind accepting that.

I do not gather that you dissent, either, from the view that the exhalation must get rid of some of the minute proportion of the cocaine that there would be in the drug?—Possibly, but what remains in gives rise to very marked symptoms.

I do not know whether you ought to say that.

Mr. Justice Ridley: Really, that does not seem to answer the question; it is simply confusing. What have we got to do with the symptoms? It does not give rise to the symptoms at all in some of the cases. We are dealing with quantities. Leave out the symptoms.

Mr. Smith: I am going to ask you some questions about the symptoms in a moment, but leaving symptoms quite out of the question, do you agree that a considerable proportion of the cocaine, a very minute proportion of the cocaine which we know to be in a drop, is got rid of by exhalation?—I should think a very small quantity.

Perhaps Mr. Tucker will just take some of that in and discharge it. (The plaintiff did so.) Is not your view that a very inconsiderable proportion of cocaine is discharged?—Not inconsiderable. (The plaintiff repeated the operation.)

You would not form an unfavourable prognosis of Mr. Tucker's case with those two applications?—No, I think he can do it yet again.

You would not like to do it yourself?—No, I am very susceptible to cocaine.

You are not a victim to the cocaine habit?—No, thanks.

Do you mind telling me scientifically, in that exhalation, which would appear to cover a considerable volume of vapour, very little of the cocaine would be discharged?—Because I think there is very little in that.

Your point is really that very little would be discharged in the exhalation because there has been so very little in the exhalation?—Yes.

We are reaching common ground, then.

Mr. Justice Ridley: What proportion of what is taken in will come out?—I do not know at all.

Mr. Smith: You cannot form any view?—No.

I will put a strong case. If it all came out, these gloomy views which we are encouraged to form about the cocaine risk we can put aside?—If it all came out.

You do not know how much comes out?—No.

If you are wrong about the proportion which stays in all these melancholy prognostications fall to the ground?—Yes, but I think by the fact that it relieves so quickly a good deal must be taken.

You do not think it is the temporary passing through that would alleviate at all?—No.

That is your only reason for forming this view?—Which view do you mean?

The only view up to the present time which you have announced to me.

Mr. Justice Ridley: Is the cocaine the only thing that alleviates asthma?—I should think the atropine and possibly also the nitrite of sodium.

Mr. Smith: What proportion of those stays in?—I do not know anything about the proportions that stay in and I do not know anything about the proportions that come out. I know it relieves the symptoms and has a marked effect, and therefore some must stay in.

You do not know what proportion of these ingredients remains in the system, or whether any of them do?—They must remain there, that is obvious.

You do not know how much?—I do not know.

However minute they may be?—I do not know how much remains in or how much comes out.

Of course, if the greater part of it is expelled it would considerably modify the view you have expressed?—If it is, but I think it is not.

Your view, as I understand it, is that it is not a prudent thing, nor indeed a safe thing, for this to be used in this way without medical supervision; is that so?—I think it is imprudent.

That is as far in the direction of the unfavourable sense as you would feel able to go?—I should say even more; I should say it is very unwise for a patient to be constantly using a remedy of this kind.

Mr. Justice Ridley: Suppose he used it for seven years?—Then I should think it seven times as unwise as if he used it for one year.

Yes, I quite understand that, but what would be the effect upon his health in seven years?—I think you could only tell by examining the individual case that had used it for the time.

Mr. Smith: Of course, the learned counsel did not take much opportunity of cross-examining the witnesses on that point.

Mr. Justice Ridley: We have had witnesses who have used it for fully that time.—I think our experience would be we could bring plenty of patients who had had to give it up because it has upset them.

Mr. Smith: I am at some difficulty in dealing with this point. If a patient had been using it for seven years your view is his case would be seven times as bad as if he had been using it only one year?—I think he would be worse at the end of seven years than if he had used it for a much shorter period of time.

Is Sir Stephen Mackenzie a man of high reputation in his profession?—I believe so.

Do not you know him?—Not personally.

But you know his reputation?—Yes.

You know it is high?—I grant you that.

Do you wish to make any qualification?—No.

None at all?—No.

Then without qualification his reputation is a high one?—Yes.

I suppose he is quite as capable as you are of making an analysis?—Well?

We will not make comparisons; they are invidious. You have heard that Sir Stephen Mackenzie has sent more than once for this specific?—I have not heard it.

You heard it in evidence, not cross-examined too?—I had not heard it.

Then assume it to be the case.

Mr. Eldon Bankes: I did not object, but, of course, there is no evidence that he took it; he may have sent for it for analysis.

Mr. Justice Ridley: When did you get that evidence in?

Mr. Eldon Bankes: There are a good many things said which I did not object to. It came out in this way: Mr. Duke in his opening said he was going to call people who used it, and, amongst others, Sir Stephen Mackenzie. Thereupon he was told Sir Stephen Mackenzie was not here, and the thing dropped; that was all that happened and I think my friend ought to confine himself to that.

Mr. Justice Ridley: There was something else said.

Mr. Smith: Yes, let me remind your lordship. What happened was, my friend Mr. Duke inadvertently said he was going to call Sir Stephen Mackenzie. In point of fact we attempted to serve a subpœna on Sir Stephen Mackenzie and discovered that he was on the continent. We then tendered the evidence of the plaintiff that Sir Stephen Mackenzie for a period of six years had been in the habit from time to time of sending for this specific. We could have put in letters if my friend had cross-examined in any way.

Mr. Eldon Bankes: You could not have used the letters. Really, you are going beyond what you ought

Mr. Smith: My lord will tell me whether I am.

Mr. Justice Ridley: "Sir Stephen Mackenzie is one of

Did you hear one of the gentlemen say that he had been for years under medical treatment and got steadily *worse*?

Mr. Justice RIDLEY: In Lord Ashburnham's case he went to a very eminent doctor, and finally the doctor told him to go to Mr. Tucker.

Mr. DUKE: That is quite a common case, is it not?

Mr. Justice RIDLEY: Then he recovered.

The WITNESS: Of course, he may not have had consistent and thorough treatment. I do not know the particulars of the treatment which he had before he went to Mr. Tucker.

Mr. DUKE: But he told us; he said his doctor had seen him on and off and had been treating him for 20 years, and then told him, "You go and get Tucker's specific"; do you know that?—Yes, I have heard that.

And I suppose you believed it?—Certainly.

Have you any sort of doubt at all that that is quite a common thing in the treatment of asthma by the methods which you find in the books?—I do not think that it is a common thing for ordinary medical treatment to fail and for this particular form of treatment to have to be taken up.

I never asked you that. Is it a common thing in the treatment of asthma that the treatment found in the books is practically powerless to prevent the progressive liability to asthma?—I should not say it was common; I should say it does occur.

Does it frequently occur in serious cases of asthma?—Yes.

Do you think it is a fraud for a man who has a specific for the treatment of such cases as that to charge £3 for it to a man who wants it? Do you think it is necessarily a fraud?—No; but I think a man ought to be qualified to sell the preparation.

Mr. Justice RIDLEY: That is another matter altogether. I have not a word to say about that, but that is not what has been stated in this libel. I say it again for the third time.

Mr. DUKE: You think he ought to be qualified. Does that mean that nobody ought to interfere with the relieving of human ailments unless he is a qualified doctor, because he may do more harm than good; is that what it means?

Mr. Justice RIDLEY: Will you take it in this way: He was the agent for his brother, who was a qualified man; his brother was a qualified doctor in America and had taken a degree, and he is his brother's agent. What do you say to that? Does that make any difference? He is not a doctor but he trusts a man who is and who has made the mixture.—I think that this particular mixture ought not to be sold indiscriminately by a person who is not qualified.

Mr. Justice RIDLEY: I will not press the other point.

Mr. DUKE: Is your view that Dr. Tucker or Mr. Tucker ought to hand the thing over to the Society of Apothecaries, for instance, in order that qualified medical men may earn their livelihood by dealing in it; is that it?—No; I think that these powerful drugs should not be sold except by a person qualified to sell them, either a chemist or a doctor.

Then is your view that Mr. Tucker should forthwith cease to sell this thing?—I think he should comply with the conditions of the Act.

I wish you would tell me whether your view is that as a matter of propriety, whether people want it or not and whether it will cure them or not, he should cease to sell it?—No.

Then you think he may go on selling it?—I think he should comply with the proper conditions.

What conditions do you recommend—as a matter of honesty only; I am only dealing with honesty. What conditions would you recommend which you say would entitle him honestly to sell it as a valuable specific to people who are suffering from asthma?—I think that the preparation should be labelled "Poison" for one thing.

Do you know that 25,000 people have been using this—that is, 25,000 separate commodities of this kind have been sold to patients who required them in the last ten years?—Yes.

And that not a scrap of harm, so far as appears up to the present time, has come to any of them, and that they are glad to come here and say that it has done them good? Do you realise that?—I do not realise that not a scrap of harm has been done to any of them. I have that stated, but I should be inclined to doubt that.

We will take it as far as it goes. Have you heard of any harm that has been done to the witnesses who have come here up to this time?—I have heard of none to any of those witnesses.

Take it that that is the state of things with regard to them and that there are 25,000 other people who have been using this thing during the last nine years. What practical necessity is there—I do not know whether there is or is not a statutory necessity, that may have to be considered—but what practical necessity is there for labelling this little phial "Poison," whereas it has never hurt anybody so far as we know?—I should say probably it has done harm to some of those 25,000.

You think it has, although Mr. Tucker has not heard of it?

Mr. Justice RIDLEY: Even in the quantity contained in it?—Yes.

Mr. DUKE: I must ask you one or two questions, and I shall not take long about them, with regard to that statement of yours. You gave me your quantities of cocaine and atropine?—Yes.

Which of them would you regard as in your view the more deleterious?—The cocaine.

And you said there is 2·28 of that. Is that per cent. or grains?—Grains per fluid ounce.

That is 2¼ in 440, is it not?—Yes; it would be 1/200th part of a grain in a drop.

Mr. ELDON BANKES: Is that cocaine or atropine?—That is cocaine.

Look again. Have you not made a mistake?—It is 1/195.

Mr. DUKE: How much will *that* exhaust, a drop or less than a drop, do you think (squeezing the bulb of the atomiser)?—Less than a drop.

How many of them would exhaust a drop?—I have not made the experiment.

I only ask you to tell me roughly.—I daresay about 100.

So that when a man has discharged it 100 times he would have used up about a drop?—Yes.

You know what the process is, when you have learnt it, to fill the lungs by that discharge?—Yes.

How many of them do you think a man could stand in his lungs at a time?

Mr. ELDON BANKES: One of your witnesses said ten.

Mr. DUKE: Somebody said you can take ten.

The WITNESS: *From three to ten.*

Mr. Justice RIDLEY: In each squeeze there is 1/20,000th part of a grain.

Mr. DUKE: Let us follow that up.

Mr. Justice RIDLEY: It is almost impossible to think of.

Mr. ELDON BANKES: But it does good and may do harm.

Mr. DUKE: The specific does good. You flatter yourself that you have found out the ingredients.

Mr. Justice RIDLEY: You do not take the whole 2·28 of a grain at once; you have six months to spread it over. Does not the effect of the first administration of squeezes pass off before you come to the time when it is necessary to administer the next?—Certainly.

Then it is not an accumulative effect: the quantity taken each time is what has to be looked at. You cannot take it all together and say that you have taken two grains of it?—No.

That is quite clear, is it not?—Certainly.

The effect passes off?—Yes.

Mr. DUKE: I want to make it quite clear and see what mischief it is said that Dr. Tucker is doing.

Mr. Justice RIDLEY: There are 100 squeezes wanted to a drop.

The WITNESS: In 100 squeezes there would be about 1/200th part of a grain.

Mr. Justice RIDLEY: You are quite right.

Mr. DUKE: So that in one squeeze there would be 1/20,000th part of a grain?—One squeeze would probably not do any good.

I knew that would be said. We will just follow that up.

Mr. Justice RIDLEY: When he is thoroughly getting on he can take ten at a time.

Mr. DUKE: Somewhere between three and ten fills the lungs. Suppose you are a confirmed inhaler and you take six—or I will take the extreme case of a man who took 10. He would inhale 1/2000th part of a grain of cocaine with each volume of the vapour, as I call it, which he discharged and which got into his lungs?—Yes.

That is, he would have the possibility of absorbing it?—Yes.

He would inhale 1/2000th part of a grain and he would have the possibility of absorbing some of it?—Yes.

Will you tell me what proportion of the vapour which is inhaled into the lungs would be in contact with the lung surface?—It would be impossible to give you——

Is it not a minute portion?—A considerable portion.

Is not the greater part of the vapour which is inhaled this by Dr. Mitchell Bruce, and no question was asked by my learned friend at all to suggest that it was under his supervision.

Mr. Justice RIDLEY: He was never told there was any cocaine or atropine in it and it is obvious there was no particular care or supervision in it in his case because he did not know there was any poison in it. He said: "I was not told it contained cocaine or atropine"; therefore it is clear I should think that he was recommended to take it according to the instructions. Perhaps I am wrong. You see what I mean. I will read the whole evidence if you like.

Mr. SMITH: I should be glad if your lordship would just remind us.

Mr. Justice RIDLEY: "I am 67 years of age. I had asthmatic troubles for five or six years, violent attacks of breathlessness, principally in the daytime, not at night. I tried many treatments and on one occasion went to Mont d'Or and Nauheim baths. They were not much use for it. I consulted several doctors, and I tried all recognised remedies. A year ago in November I had an acute attack, and I consulted Dr. Mitchell Bruce of Harley-street. He gave me a tonic."

Mr. ELDON BANKES: Would your lordship stop there for a moment. This is what I relied upon, and therefore I did not ask any questions:—"Did you consult anyone?—I consulted Dr. Mitchell Bruce of Harley-street.—Was that the first time you had been to see him?—No; off and on I had seen him a good many years, I daresay 20 years or more perhaps"; so I took it that he was Dr. Bruce's patient.

Mr. Justice RIDLEY: Very likely he was. I have not taken that down, but I have no doubt it is right.

Mr. ELDON BANKES: I understood he was a patient of the doctor.

Mr. Justice RIDLEY: He did not state it at this moment because this is the evidence-in-chief.

Mr. ELDON BANKES: I was reading the evidence-in-chief and that is why I interrupted. It comes just between what your lordship took down. You do not seem to have taken down that answer.

Mr. Justice RIDLEY: No, I do not.

Mr. ELDON BANKES: No doubt it did not occur to your lordship as being material.

Mr. Justice RIDLEY: May I go on?

Mr. ELDON BANKES: Certainly, my lord.

Mr. Justice RIDLEY: "He gave me a tonic, but as to breathlessness could only recommend Mr. Tucker's cure." I daresay those words are shortly taken too. "A Paris doctor told me of it before. I found the address out from Messrs. Savory and Moore, and went straight to the place. There I saw a lady and she showed me the atomiser. I bought it outright, and have used it constantly since, especially in London. It removes the breath troubles absolutely. It has not the slightest ill result, and I think I am distinctly better than I was a year ago. I have once had to buy some more liquid. Cross-examined: The attacks came perhaps six or seven times a day." Then I have no doubt other questions were asked, but this is all I have got in answer. "London is a very unfavourable place. I do not use it except when I want it. I gave the lady information about my complaint. I was not told it contained cocaine or atropine." That is all I have about Lord Ashburnham.

Mr. SMITH (to the witness): Taking it quite shortly, your view is that if that advice was given and no arrangement was made for supervision that is extremely unwise?

I personally should think it was unwise.

You will not put it higher than that; you do not agree with it yourself?—I do not agree with it myself.

But you recognise that a competent medical man might take a different view?—He apparently knew Lord Ashburnham's state of health very well, and whether it was possible for him to take this.

Then your view is that if a doctor know his patient's general state of health he might with propriety recommend this specific without arranging for supervision?—I do not think so. I think he would have to assume that the patient would consult him afterwards, to see whether the specific was doing him any injury or not. I should certainly in my own case.

Supposing the doctor arranged that in case the specific was doing injury afterwards he should come and consult him, you would see no objection to it?—Less objection than otherwise, but personally, as I say, I should not use it. I mean to say I cannot defend what other men might do. I personally should not use it.

You have heard Mr. Tucker say that he had on his books 300 doctors of medicine?—He might have.

You think they are all making a mistake?—I think they are unwise, and I am bound to say so.

Do you mean unwise in the interests of the profession?—No, unwise in the interests of the patient in a great many cases.

Mr. Justice RIDLEY: In their own cases that means?—Yes.

Mr. Justice RIDLEY: You do not think their cumulative experience in actually making use of this specific is likely to be of no weight. Does not their cumulative experience coming in the shape, in many cases, of repeated orders impress you?—Not very much.

Not 300 doctors? They are all qualified.—I daresay they are.

Mr. ELDON BANKES: May I suggest that the fact that 300 doctors have once ordered it (if it is the fact, and I am not disputing it) does not show that they continued to use it, or that they did not cease the use of it afterwards. You are pushing the answer farther than it will go.

Mr. SMITH: The plaintiff can give the names and addresses of all the doctors, and I ostentatiously invited my learned friend to ask for them, when, of course, the orders and repeated orders could have all been given. My learned friend, if I may venture to say so, was extremely well-advised not to ask for the names, and therefore they were not given.

Mr. ELDON BANKES: The names would not help you.

Mr. SMITH: Perhaps the suggestion is that all these doctors gave one order.

Mr. ELDON BANKES: No, it is not indeed, but I submit you are pressing the answer farther than it legitimately will go.

Mr. SMITH: I do not want to be unfair, but what it comes to is this. The witness says however many times the doctors ordered this specific it would not change his view.

The WITNESS: Not the slightest. I have seen the evil effects myself of cocaine and of this remedy, and therefore it would not influence me whoever thought they might advise it.

You have seen the evil influence of cocaine in the case of persons addicted to the habit, and that would not change your view in reference to this atomiser whatever 300 or 3000 doctors might say?—No, because I have seen it with this atomiser.

Take, for instance, the case of Mr. Bateson. You did not hear Mr. Bateson give his evidence?—No.

He is a member of the Bar, you know?—Yes.

He has to make extensive use of his thinking powers. I want to ask you about that case. That was a gentleman who utterly failed to gain relief from the medical faculty.—May I ask what the medical faculty did for him?

He said they administered various poisons to him.

Mr. Justice RIDLEY: I think as it is short I might read that evidence also.

Mr. ELDON BANKES: He said they fed him on strychnine.

Mr. Justice RIDLEY: I will read what he said as far as I can; that is the best thing. "I am a barrister-at-law. I have been liable to asthmatic attacks from childhood until I bought Tucker's specific about four or five years ago. I am now rising 42"—that is what he said. "It got worse and constantly I could not sleep at all, but after I bought this I have been able to sleep perfectly well and have had no trouble with asthma at all. My earliest recollection is being under Sir William Jenner. I had recurring attacks then, though I daresay there was relief from time to time"—from the medical treatment that means. "The longer I have used it the less I have to use it. I hardly require it at all now. I pay about 8s. for either 12 or 18 months which would be adequate certainly for 12 months. I volunteered my evidence. Cross-examined: I have been told it contains poison, but all the doctors have fed me on poison. There is nothing on the bottles. I had to use it constantly when I first started. Doctors have ordered me cocaine for hay fever. Re-examined: Sir William Jenner fed me mostly on arsenic, and it was suggested to me to use cocaine for hay fever." I think it was he who suggested it.

Mr. SMITH: Yes, I think it was.

Mr. Justice RIDLEY: "I have never used care with it. I used it as frequently as I wanted it, perhaps three or four times in half an hour, and relief always came very quickly."

The WITNESS: It seems obvious that his diet now is and I submit that is always so. It is not a proper question to put to a witness when it is the question which the jury have ultimately to decide.

Mr. DUKE: The answer to that is that this is an expert witness——

Mr. Justice RIDLEY: You will have to put a department of the case, and ask him if that is fraudulent.

Mr. DUKE: Yes, I could do it in that way; but I am not asking him as to whether he considers that the plaintiff is fraudulent, I am asking him whether there is anything which he has heard in this case, as far as it has gone, upon which he would say that the plaintiff had been fraudulent in selling this specific as a remedy for asthma, and that I submit I am entitled to put.

Mr. ELDON BANKES: I object to the question, and I submit that it is not relevant.

Mr. Justice RIDLEY: I do not see the distinction. I think you must be content with putting the question and drawing the inference. I shall have to ask the jury that question, I can see.

Mr. ELDON BANKES: Very well, I will leave it where it is.

THIRD DAY.

Mr. Justice RIDLEY: The jury have made application to the court with regard to the length of this case. I do not know whether you can come to any agreement.

Mr. ELDON BANKES: My friend and I have agreed that the jury shall treat each day as a separate case.

Mr. Justice RIDLEY: It is proper, and no doubt you will agree it is proper.

Mr. ELDON BANKES: We have agreed.

Dr. WILLIAM HENRY WILLCOX, recalled. *Re-examined by* Mr. ELDON BANKES.—You were asked yesterday with regard to your practice, and you said you have a consulting practice?—Yes.

And you also spoke about the out-patients at St. Mary's. Do you hold an appointment at St. Mary's?—I am physician to the out-patients at St. Mary's Hospital, and also physician to the out-patients at the Great Northern Central Hospital.

I will come to deal with your experience with regard to them in a moment. You were asked a good many questions yesterday with regard to the quantity of this vapour, as we have agreed to call it, that could be absorbed by a patient, and you were asked about the effect of ten compressions. Have you got a copy of Dr. Tucker's instructions?—No, I have not. (Document handed to witness.)

Will you turn to page 6? You will find there the directions that Mr. Tucker sends out to his patients?—Yes.

You see there he says that the length of time required in using the atomiser in order to get relief will vary from two to five minutes according to the severity of the attack?—Yes.

And also, on page 5, he indicates that the right way to use the vaporiser is to inhale and compress during the inhalation?—Yes.

I am only taking this as a test, but one of the witnesses, Mr. Symonds, has told us that during one inhalation he makes ten compressions?—Yes.

How many inhalations would a patient make in a minute?—He might make half a dozen, I should think.

So that in one minute at that rate he would get 100 compressions?—60.

Supposing he were to continue that for five minutes he would get 300 compressions?—Yes.

Mr. Justice RIDLEY: That is if he went on constantly at that rate.

Mr. ELDON BANKES: But your lordship will see that Dr. Tucker says, if I may use the word dose, that the dose continues from two to five minutes, so you are to compress from two to five minutes. Of course, I quite agree it depends on the skill of the patient how many he will be able to take in.

Mr. SMITH: Your lordship will recollect he was not cross-examined when he said the strongest man could not do it more than ten times running.

Mr. ELDON BANKES: Mr. Symonds said he could do it ten times.

Mr. Justice RIDLEY: He said he could not do it more than about three times when it began, and when he got better he could do it ten times.

Mr. ELDON BANKES: I must get a figure. I quite agree it will be a maximum figure, but I only want to get the maximum to compare it with Mr. Duke's suggestion about the minimum figure.

Assume that for the moment; that would be 300 compressions in five minutes?—Yes, and that would correspond to about 1/66th of a grain of cocaine.

So that in order to absorb one grain at that rate a patient would have to take 66 doses?—That is so.

That is to say, apply the vaporiser according to those directions 66 times and to use it at that rate?

Mr. Justice RIDLEY: There is a mistake in the *Times* this morning. I suppose it is my fault for making it, as usual; but I am reported to have said this: that there was 1/20,000th of a grain in a drop. That is not what I said, nor did anybody. It is 1/20,000th of a grain in a squeeze. It is a most important mistake, and I cannot believe I said that.

Mr. ELDON BANKES: It is very confusing.

Mr. Justice RIDLEY: It makes people believe there is a very much smaller proportion of cocaine in this stuff than there is. People ought to be more accurate, as I said before. I do not think I said that, but if I did it is, of course, wrong.

Mr. ELDON BANKES: It is very difficult to express oneself accurately in this case.

Mr. Justice RIDLEY: I should have thought that persons dealing with this case would have understood what the point was.

Mr. ELDON BANKES (to the witness): That would take 66 doses?—Yes.

Is asthma a peculiarly distressing complaint?—Yes, very distressing.

Would a patient naturally fly to anything which would give him or her relief unless they were warned against an excessive use of it?—Yes, certainly.

With regard to the effect of cocaine, you were asked yesterday how long it would take a patient to excrete the amount of cocaine that they would take under this system in a day, and you told my friend Mr. Duke?—Yes.

But does the fact of excreting the cocaine do away with the effect?

Mr. SMITH: My friend had better not lead quite so much.

Mr. ELDON BANKES: Does the effect of cocaine on the body remain although it may be excreted?—Cocaine is a very powerful poison and it causes damage to the heart cells and to the brain cells.

Mr. Justice RIDLEY: I do not think you answered the question; please answer the question.—The damage would remain to the cells of the body.

You say it would remain?—Yes, and I was explaining why.

You say it is a cumulative effect?—I say the effect is cumulative, although the poison itself is excreted.

Mr. ELDON BANKES: In your opinion, in the course of time would the effect of these quantities of cocaine, if used largely, have a material effect upon the patient's health?—Yes; undoubtedly they would be injurious.

Mr. Justice RIDLEY: They must be?—Yes, must be.

To anyone?—Yes, if continued for a long time in large doses.

Mr. SMITH: What is a long time?

Mr. Justice RIDLEY: We have had a number of people who say it was not.

Mr. ELDON BANKES: Does the fact of these people coming here to say it had no bad effect upon them affect your opinion at all?—No.

Will you say why not?—Because I know how powerful a poison cocaine is, and that if its use is continued for a long time it will, I know, cause damage.

Mr. Justice RIDLEY: What do you mean by a long time, may I ask?—It depends on the individual.

Mr. ELDON BANKES: Does the susceptibility to cocaine vary enormously in different persons?—Yes, a very great deal.

And some people take it for a long time in considerable quantities without it doing them any harm?—Yes.

Whereas the same amount to another person in much less quantities and for a very much shorter time would do them great harm?—Yes.

Is that a reason, in your opinion, why a patient who is taking cocaine in any quantities should be carefully watched by some competent person?—Yes, I think it is most important.

Mr. Justice RIDLEY: That is not what you have said in the libel.

Mr. ELDON BANKES: I am sure your lordship will forgive me.

Has Mr. Tucker defrauded Mr. Bateson, for instance?—No, but he has defrauded patients whom I know because he has not cured them and the pamphlet says that it produces a cure.

This is your argument and I shall have an opportunity of dealing with it?

Mr. Justice RIDLEY: Does a doctor always make a cure? He does not promise.

It is very hard on the doctor if he is a fraud because he does not make a cure?—I do not think he would promise to cure.

Mr. Justice RIDLEY: I think I have heard him do it.

Mr. SMITH: Then your view is that Mr. Tucker is a fraud?—I think it is a fraudulent proceeding. I do not know that Mr. Tucker himself is——

Let us be quite clear about that before the jury. Your view is that this is a fraudulent proceeding, and as you have heard, Mr. Tucker is responsible for it, and you think he is taking part in a fraudulent business?—I think it is a fraudulent business to send out a remedy or specific, whichever you like to call it, which you state will cure but which does not cure.

That is your whole reason for saying so—this statement in the pamphlet? Have you the pamphlet there? "Specific for the perfect relief and cure of asthma and hay fever." That is the only reason you have got for saying to the jury what nobody else has said so far, that this is a fraudulent system?—I think it is a fraud so far as it promises what it does not and cannot carry out.

And this is what you found yourself on?—There are other statements in that which are not true.

I would like to have all the statements which would lead you to take the view that this is fraudulent. We are getting further than we have done before. This is No. 1. I will hand you the pamphlet. (Same handed to the witness.)—Perhaps I might wait for a copy in which I made some notes on the margin.

Have any copy you like. (Copy handed to the witness.) Just refer me to the page of the pamphlet which led you to form the view that this is a fraud?—On page 6 there is a statement here: "You will notice by the above instructions that it is necessary for the vapour to reach the lungs in order to arrest the attacks, heal the mucous surfaces, and cure the disease."

Page 6 of what?—Of this pamphlet.

Mr. Justice RIDLEY: That is not the pamphlet; that is the instructions.

Mr. SMITH: Your lordship recollects the evidence that this was written by Dr. Tucker.

Mr. Justice RIDLEY: Yes.

Mr. SMITH: "You will notice by the above instructions that it is necessary for the vapour to reach the lungs in order to arrest the attacks, heal the mucous surfaces, and cure the disease." I note that. Is there anything else?—I do not agree with what is here on page ——

I do not mind what you agree with or what you disagree with; I do not care in the least.

Mr. Justice RIDLEY: What do you want to say about that paragraph, "You will notice," and so on? I thought you referred to that.

Mr. SMITH: Where is the dishonesty? that is what I want.—I do not think it is true; it is published as a fact.

You have given me one statement, or two statements, that is all.—Here is a point in which this vapour is supposed to heal the mucous surfaces. So far as I know, there is no wound there or anything which you can consider is absolutely anything that you can heal in the sense of healing a mucous surface by blowing in this specific, this oil.

You think he is wrong?—I think he is wrong.

And your suggestion to the jury is that it is a fraudulent statement?—I think it is a fraudulent statement.

Is there anything else?—On page 7 of this larger book, the top paragraph, it says, "We now offer to suffering humanity the result of 20 years' experience which has finally worked out a cure for asthma and hay fever, as well as all other catarrhal diseases of the air passages." That is absolutely untrue.

You say it is absolutely untrue?—Quite.

So that even if witnesses come forward to say that they can always cure attacks of asthma by the use of that it does not influence you at all?—"As well as all other catarrhal diseases." I say that that is an untrue statement.

I want to have all those passages on which you found yourself. Are there any more?—There are the last five lines on page 8. You will see it is stated: "We reverse the order of things and think we can prove that the catarrhal affection is the primary cause of the spasm and not the effect." That I do not think is true.

That is fraudulent, is it?—I think it is a fraud to publish it as fact and lead people who cannot understand.

It is not a thing as to which there can be any honest difference of opinion?—I do not think that.

Are you sure?—Yes, I think I can bring plenty of evidence to prove it.

You are charging dishonesty?—Yes.

You do not do that on hypotheses, I suppose?—No.

You are sure that this is such an error as to be incompatible with any theory of honesty at all?—I think to put it on that broad basis and to send this out stating it as a fact is taking advantage of their credulity, which is otherwise a fraud.

I quite understand your general view but I am now asking you for the specific grounds upon which you base that. Do you mind dealing with those first and you can afterwards get back to general grounds. Are there any more passages?—This is on page 6, the second paragraph: "Asthmatics who have organic heart disease or weak heart can use the remedy with perfect safety."

Your view is that they cannot?—My view is that they cannot.

Mr. Justice RIDLEY: Is that your personal experience?

No; it is not my personal experience, because my line of work of recent years has not led me to treat heart disease.

Mr. SMITH: And although it is not personal experience you say it is a fraud; you state that?

I think the statement will be borne out by other witnesses.

Did you hear one or two witnesses who were called yesterday, members of the medical profession? Were you here?—I was here from 3 to 4 o'clock.

Were you here when Dr. Clark was called?—No.

He was a fully qualified medical practitioner?—Yes.

Do you know that he said he suffered himself from asthma and that eight years ago he obtained Tucker's specific, that he got instant relief and has used it continuously ever since with benefit and has never found the slightest craving for it?—He personally might have done so.

You would agree that so far as he was concerned it was a remedy?—I have told you already that I have agreed that many people might use this under supervision. He being a medical man might know the symptoms.

It might be used with great advantage.—He may use it with advantage, yes. So might you use morphia with great advantage.

But the evidence is not that people have used morphia with great advantage; I am dealing with asthma.—Excuse me, one of the most potent and easiest methods of relieving a violent spasm of asthma is the injection of a small dose of morphia.

Mr. Justice RIDLEY: He also said this: "I have recommended it in a number of instances and it will do nobody any harm."—I cannot agree with that statement.

If another medical man says that, though you do not agree with it, it is rather strong to say that is a fraud. I suppose you will say that is fraud?—No; it is personal experience.

I suppose this is this gentleman's personal experience too. I want to know where we are. This pamphlet is founded upon the personal experience of Dr. Tucker. Therefore one is the same as the other, except that one is given upon oath and the other is not. It is rather strong to say that this is fraud.

Mr. ELDON BANKES: Your lordship will remember that Mr. Tucker said here over and over again he did not claim that this specific cured asthma.

Mr. Justice RIDLEY: Yes; I know he did, and I do not think it is true to say that he did claim it.

Mr. ELDON BANKES: There, again, that is a matter of opinion. A person may fairly form the opinion that he did claim it. This gentleman formed the opinion that where he says on page 8 of these instructions, "If necessary repeat the third time and by thus persevering with the treatment the disease can be perfectly controlled and finally cured," he was drawing the distinction as I submit between relief and cure.

Mr. Justice RIDLEY: You have to read the whole pamphlet together.

Mr. ELDON BANKES: Certainly.

Mr. Justice RIDLEY: I think reading pages 6 and 7 together you will see that he does not claim a cure for the asthma in the sense in which this gentleman thinks he does.

Mr. ELDON BANKES: Well, I was going to ask you now what has been the effect that you have noticed?

Mr. SMITH: I should like to ask your lordship, unless it is taken in the same way and substantially in the same proportion, whether or not this would be evidence. There is no dispute, of course, in many cases of persons who have taken cocaine in large quantities, that they are very much injured by it. If he is going to speak to persons who have taken appreciably the same dose and the same atomiser of course I do not object.

Mr. ELDON BANKES: I am speaking of atomisers, and I am speaking merely of the use of the Tucker specific.

The WITNESS: I suppose I may not give the case where I am told "I have given it up because I have felt it growing upon me."

Mr. ELDON BANKES: I want you to tell the jury what is your experience of the use of Tucker's specific with any patient or patients that have come to you.—My experience of it is that it gives relief and that the relief leads them to continue taking it under circumstances which are disadvantageous to themselves. May I explain that? I mean this: supposing a patient is suffering from asthma and takes this remedy he gets relief. The asthma may be caused by some condition which could easily be relieved otherwise, but because he gets relief the patient continues to take the remedy, and the time goes by when the real cause of the asthma could have been removed once for all had he only known of it, but he is satisfied with the relief and he goes on until it is impossible to remove the real condition, thus making it impossible to effect a cure.

So that the time passes by in which the patient can really be cured by anybody?—Certainly.

Is it possible for the specific itself to effect a cure?—I have never known a case.

Mr. Justice RIDLEY: Asthma, I believe, cannot be cured at all?—Yes; it can be cured, but I have never known a case cured by this so-called specific. I should like to state that I do not say all cases of asthma can be cured, but there are certain cases many of which I am quite sure can be cured permanently.

Mr. ELDON BANKES: Are you familiar with what is known as the cocaine habit?—Quite.

How does that affect a patient?—Well, it is practically like all drug habits. Supposing we were to take an ordinary weak solution of cocaine, one of the commonest methods of using it is for the patient to obtain a small vaporiser, nebuliser, aeriser, or whatever term you like to give to the instrument, and just blow it into each nostril and draw the vapour through. In the course of a few moments, supposing they are suffering from a little obstruction or difficulty of breathing, all that passes off. Then the patient experiences a sensation of what is called by a French phrase the *bien-être*—that is to say, a sense of well-being, a sense of elation. No task would be too great for you to overcome. You are capable of any amount of energy. Then after that comes the inevitable reaction in which you get hopelessly depressed. Then you go back to your remedy again, and so the thing goes on until the patient becomes an addicted cocainist, as we call it. Besides the effect it has on his mental condition in the weakening of the mind it will make him irritable and nervous, and in the chronic cases they suffer from sleeplessness and want of appetite. I am speaking now of an ordinary bad habit of cocaine.

Is it worse than all the drug habits?—I am sure it is worse than the morphia habit.

And more difficult to cure?—It is more difficult to cure because the patient in the morphia habit will like to get cured and try to help you to cure him, but the cocainist does not want to get rid of his habit, and will try and elude you in your efforts to cure him.

Is it a habit very easily to be acquired?—Very easy.

And in certain patients who are extremely susceptible the cocaine habit is acquired by the use of small quantities?—Possibly, because in the individual case the small quantity may have a very great effect upon him.

In your opinion is the use of this specific for prolonged periods calculated to produce the cocaine habit?—Yes, I think it is calculated to do so.

I think you yourself have, have you not, written or lectured upon the precautions that ought to be taken with regard to the use of cocaine?—In the last edition of my work on diseases of the nose and throat I have devoted a paragraph to it, in which I have laid stress on the fact that I think medical men ought to be very careful in allowing a prescription containing cocaine, even in small doses, to pass into the hands of their patient because they never do know what will be the outcome of it provided the patient is addicted to its use.

Mr. Justice RIDLEY: I do not think I can take that down: it is the same thing over again taken out of your book.

Mr. ELDON BANKES: Of recent years have the profession generally taken much greater precautions with regard to prescribing cocaine than was formerly the case?—Yes, especially in the United States of America, where it is better known and its evils.

Is that because of the increasing knowledge of the bad effects of the use of cocaine?—And the knowledge that the public very easily attain the habit of using it.

Has your attention been called to the case of the man Cushing who died of consumption?—Yes, I read of it.

Are you able to express any opinion as to the desirability or otherwise of using cocaine in cases of consumption; would that come under your notice?—It would in the case of consumption of the throat, where one uses sufficient just to obtain ease before taking food sometimes, but one would never give it as a continual form of treatment—I mean to say, in the form of a prescription.

Mr. Justice RIDLEY: I do not think that would be material, because this is not recommended for consumption.

Mr. ELDON BANKES: No, but your lordship will remember that the origin of this statement either by the coroner or by us was, as your lordship will see stated in the article, it had been used by a man who died of consumption.

Cross examined by Mr. F. E. SMITH.—Before I pass away from that I want to ask a question about this drug habit. As far as taking cocaine is concerned, do you say the cocaine habit is easily acquired?—Yes.

I suppose that would be the same as far as all drug habits were concerned?—No, because all drugs have not that seductive influence which cocaine has.

Has not morphia, for instance, got a seductive influence?—Morphia has not got the seductive influence of cocaine.

Has not it a well-known seductive influence?—But in another ten years cocaine will have a much greater reputation for seductive influence.

That is your view about it. You may be right. Tell me. What is the kind of dose where the cocaine habit in the extreme form exists that can be taken without the destruction of human life?—You mean to say, supposing a patient is a cocainist and is in the habit of taking large doses what is the largest dose?

Yes.—I do not know; I believe it varies. I believe you can take 10 grains of it, or even 15.

I suggest to you, before passing away from this, that a dose of 90 grains has been recorded over a considerable period?—That is quite possible.

I do not know whether you were present in court yesterday?—Yesterday afternoon only.

You heard the evidence that was given by the last witness?—Yes.

I mean with regard to the amount of cocaine that would be absorbed into the system by the use of this atomiser?—Yes.

Do you accept that evidence?—Personally, not on all points, I should say. I do not think it is possible to say how much is absorbed; I do not think the amount that would be absorbed really has anything to do with it.

Well, I did not ask you that.

Mr. Justice RIDLEY: I am sure it has something to do with it?—Something, but the question of the amount absorbed has really not so great a bearing as the symptoms produced by the actual amount that is administered in the individual case.

Have you got to the symptoms at all? Supposing there are no symptoms?

Mr. SMITH: Of course, we are considering it entirely without reference to the symptoms for the moment. That is the whole point of the question, but even this gentleman does not seem to appreciate it quite.

Mr. Justice RIDLEY (to the witness): You must be wrong, because the quantity absorbed must have something to do with it.—Within limits, but generally speaking, it is not the amount absorbed but the effect which the drug has on the individual case.

Mr. SMITH: Does that mean you do not attach very much importance to the amount absorbed?—Of course I do; it is the whole point.

If it is the whole point perhaps you will tell me with brevity the respects in which your view differs from that of

Mr. Justice Ridley: You may say it is "a specific for asthma," but it is not a fraud.—It is a specific for the relief of the asthmatic seizure, but not for the cure of asthma.

He does not say that. He says "A specific for asthma."—Therefore I take it we are allowed to regard it as we like and have our own opinion.

I do not follow you. I think a "specific" is something which cures and so does everybody else, I should think.

Mr. Smith: Do you really put it as a scientific proposition to the jury that when a firm of wholesale chemists describe a mixture as a specific for asthma the common-sense meaning (as you are so fond of common-sense) to put upon that is not that it is going to cure asthma? Is that *your suggestion* to the jury?—I do not say what they mean by that at all. I do not know what they mean by that. I should suggest that they know enough of asthma to know that this is not going to cure it but only to relieve it.

What I am asking is, whether, when we are told that this is in every respect similar to the preparation in question, with the knowledge, mind you, that we claim to cure attacks—"In every respect similar to the preparation in question," and is "practically a specific for asthma," do you say to the jury that this does not mean that they claim to cure it.—I do not know what they mean to claim. I do not think it does.

But if they did mean that it is fraudulent?

Mr. Justice Ridley: Will you let me see the book. (Same handed to his lordship). A specific is a cure I should think.

Mr. Smith: I should have thought so.

Re-examined by Mr. Eldon Bankes.—With regard to Oppenheimer's list, is that the list of well-known wholesale chemists which is published for dissemination amongst medical men and chemists?—Yes.

And you understand their statement to mean that it is a specific for the relief of asthma?—I cannot believe that a firm of that reputation could wish medical men to believe that they can cure asthma.

I want to know if they used the word as meaning "cure" would your opinion of them be the same as of Dr. Tucker?—I am bound to say I should consider it a fraud.

There is no distinction in your mind whether it is Oppenheimer or Tucker?—Not a bit.

If he advertises this stuff as a cure?—If a man tells me he can cure a disease, and he only *relieves* it, I consider it is—it is my way of looking at it, I use the term fraud; you may say misrepresentation; I do not care what you call it, I call it a fraud.

Before giving an opinion had you carefully read these instructions of Mr. Tucker and these other doctors?—Yes.

And rightly or wrongly did you come to the conclusion that he drew a distinction between relieving the attacks and curing the disease?—No, my impression is that the public reading that—the ordinary public—would take it that they have got something in that which is going to cure.

And it is upon that that you form the opinion which you express?—Yes.

Mr. Justice Ridley: In the pamphlet.

Mr. Eldon Bankes: And the instructions. The instructions are equally specific. Your lordship will see there is a distinction; I am not saying whether it is right or whether it is wrong.

Now a very *few questions about the many* things which you have been asked about. You were asked how much cocaine a confirmed cocainist could absorb?—Yes.

My friend referred to some statement in some book showing that a cocainist could absorb 90 grains?—Yes.

Does the frequent use of this drug or any other drug enable a person to take very much larger doses the longer they take it?—Yes, enormously. The simplest instance, of course, is morphia. A patient will be perhaps quite brought under the influence of morphia by one-sixth or a quarter of a grain the *first time* he uses it, but if he becomes addicted to it he could take five, 10, or 15 grains a day.

Can a person with the confirmed morphia habit or a confirmed cocainist, or a confirmed alcoholist take quantities with impunity which would kill any ordinary person?—Yes, *certainly.*

I mean with whisky or anything else?—Yes.

You are asked about the quantity of this vapour which would be absorbed by the compressions of this inhaler, having regard to the fact that a good deal is blown out. It is suggested to you that there may be a mere passing through of this vapour. Supposing there was anything in the nature of a mere passing through, would it have any effect at all upon the person in relieving his symptoms?—No; some must be absorbed.

And is that obvious from the fact that the asthma is relieved?—Yes.

Of course, the exact quantity that is absorbed *it is im*possible to say?—Quite impossible.

Obviously some would be expelled, and obviously some would remain?—Quite.

You have been asked questions about various persons who have been called as witnesses, and I understand you to say it is unwise for anybody to take this specific without supervision?—Yes.

But is it quite possible that certain persons may take small quantities of it without doing themselves any harm at all?—Quite.

And, of course, it may relieve them greatly?—Yes.

The necessary effect of using cocaine in this way must be to relieve the symptoms—the immediate paroxysm of asthma?—The cocaine, the atropine, and the other constituent, nitrite of soda.

They will necessarily get relief because of the action of these very potent drugs?—Yes, probably.

And in your opinion it is quite conceivable that a great many people may use it in small quantities for a long time and get relief without any obvious harm?—*Yes,* a certain number might.

And, of course, taking the case of a doctor who was using it, he presumably would be a man who would be aware of the danger of using it in an improper manner?—*Yes.*

Mr. Eldon Bankes: I wanted to call some other gentlemen very much, but Dr. Waldo, the coroner, I must call because he has an inquest this afternoon, and I must call him out of order.

Mr. Justice Ridley: Very well.

Dr. Frederick Joseph Waldo, *examined by* Mr. Eldon Bankes.—I believe you are a Doctor of Medicine of the University of Cambridge?—Yes.

Mr. Justice Ridley: And one of the coroners for the City?—I am coroner for the City of London and for the borough of Southwark.

Mr. Eldon Bankes: I think you did on the 1st of July, 1907, hold an inquest upon the body of a man named Cushing?—Yes.

Prior to that time had it come to your notice or knowledge as to what Dr. Tucker's specific consisted of or contained?—Yes.

What had you heard about it?—I had seen——

Mr. Duke: I object to what he had heard. We cannot have evidence of what he had heard.

Mr. Justice Ridley: The fact that he knew of it is admissible.

Mr. Duke: Yes, that is another matter.

Mr. Justice Ridley: We cannot have what he had heard unless he got it from Tucker himself.

Mr. Eldon Bankes (to the witness): Had you heard anything of what it contained?

Mr. Duke: I object.

The Witness: Yes, I had heard that it contained atropine and cocaine.

Mr. Eldon Bankes: My friend objects to it and if he does not choose to ask, very well.

Mr. Justice Ridley: It is only admissible if this came from information by Dr. Tucker.

Mr. Eldon Bankes: I submit not, but at this stage I will not press it.

You had heard of this specific?—I had heard of his cure.

Mr. Justice Ridley: And of its contents?—Yes.

Mr. Eldon Bankes: Was evidence given before you at that inquest?—It was.

And amongst other witnesses was there a witness, Dr. Paton?—Yes, he was the gentleman who was present after the death of the patient and he gave evidence and on my order he made a post-mortem examination *of the body.*

Before you did he give evidence as to what was the cause of death?—He did.

What did he say?—He *said* that the immediate cause of death was failure of the respiration and heart failure, due to advanced *pulmonary tubercular* disease, which is in plain English consumption of the lungs.

Long-standing consumption?—*Long*-standing consumption of the lungs. The actual words he used were what I first gave—respiratory failure and heart failure, due to long-standing pulmonary tubercular disease.

During the inquest was anything said about Dr. Tucker's our oldest patients and is still"—(looking at letter of October, 1907); that is the piece of evidence I have got.

Mr. Smith: The letter was tendered.

Mr. Eldon Bankes: The letter is not evidence.

Mr. Justice Ridley: The evidence is he is one of Mr. Tucker's patients.

Mr. Smith: Assuming that to be so, that, of course, would astonish you greatly?—No, it would not at all.

I understand your view to be that nobody gets permanent relief or any chance of a cure from this?—No; I think so.

Assuming it to be the case, would not it surprise you that Sir Stephen Mackenzie should use for years and order for years a drug that might make him a slave of the cocaine habit, which gives him no chance of permanent cure and injures his health?—I am surprised he uses it in that way.

I thought you said you were not surprised?—I am not surprised that he orders it.

Mr. Justice Ridley: But you do not deal with it. He is a patient for six years, it is said.

The Witness: Is Sir Stephen Mackenzie referring to himself or some patient?

Mr. Smith: No, to himself.

Mr. Eldon Bankes: We do not know that.

Mr. Justice Ridley: Yes, "One of my oldest patients."

Mr. Eldon Bankes: That is all he said, but it is no more evidence than that he supplied the stuff.

Mr. Smith: The evidence is that he is a patient, and my friend did not cross-examine.

The Witness: Because Sir Stephen Mackenzie used it himself it would not influence me in thinking it was a right thing to do.

You would merely think Sir Stephen Mackenzie was wrong?—I should think if he was using a drug for himself *he knew its possibilities*, and he had sense enough to know how much he could use.

But with people who have the sense to know how much they can use you think it is to be recommended?—With great care.

We are getting at something. This specific, if used with great care and among persons who understand its use, is one that may be used in cases of asthma?—Not by the lay public. I am referring to medical men.

I *guarded myself by saying* "If properly recommended"; so we are at least on common ground so far, that this specific is a good specific for asthma if administered under medical advice and with medical supervision?—Yes, I think you might say so.

You make the concession rather grudgingly, but you have no doubt about that, have you?—Well, I am only speaking for myself. I see a good deal of asthma, but I very rarely, in fact never, prescribe this remedy.

That I can quite understand, but still you accept the view I put to you a moment ago?—Generally speaking, I can conceive it might be done.

As regards the witnesses who gave evidence, you know some 20 witnesses of the highest position, both socially and professionally, have been called in court. I do not know whether you were here?—I was not here.

Assuming it to be the case that many of those witnesses stated that they had exhausted all the resources of your profession without getting relief—you follow me?—Yes.

And consulted all the most eminent physicians without getting relief, do you say such a man, if he thinks he can get relief by using this specific, is unwise *to do so*?—Yes.

All the doctors had had a try at him without success.—Are you quite sure they all had?

Perhaps they had not been to you?—No, I was not suggesting that

Assuming that they have tried competent medical advice for a considerable period without success, do you say to such a man, if he finds that Mr. Tucker's specific gives him relief, he is unwise to avail himself of that relief?—I should take very great care to point out to him the risk he was running by using it constantly.

I am sure you would, but having taken care to point out to him the risk he was running should you think such a man, having failed to get relief from the profession, was wise or unwise to get relief where he could find it?—I should think he might use the thing, but I should warn him to use it with the greatest discrimination.

So do we.

Mr. Eldon Bankes: That is the whole point; you do not warn people that it is to be used with caution. You say it is perfectly harmless and they are to use it as much as they can.

Mr. Justice Ridley: Take Mr. Symonds' evidence. He was recommended the remedy by one of the leading physicians of the West of England. He has got relief and has used it for seven years.

Mr. Eldon Bankes: We do not suggest people cannot use it and get relief.

Mr. Justice Ridley: You have said this is fraud. How can it be fraud? It is hopeless.

Mr. Eldon Bankes: Your lordship uses that expression, but supposing there are 25,000 people to whom this is sent, and of those 25,000 half have benefited and half have not. I am putting it as a supposititious case. If they say it is suitable and it is absolutely harmless and the more you take the better it will be I submit that a person who holds a strong opinion is entitled to say that is fraud.

Mr. Justice Ridley: I do not think he is; if he chooses to say a person is guilty of fraud he must prove it and justify it. In this case you have not done that. You have said the fraud was in this man, that he was guilty of fraud.

Mr. Eldon Bankes: No, pardon me, my lord.

Mr. Justice Ridley: Yes, you have.

Mr. Eldon Bankes: That is for the jury, really.

Mr. Justice Ridley: You have said it was fair comment on a matter of public interest.

Mr. Eldon Bankes: I have the authorities that I can refer to in a moment.

Mr. Justice Ridley: I know some of the authorities, and I daresay you know others to the contrary, but that is what I mean. If you had said that this is a thing that ought not to be done, that this *medicine* is a *dangerous one* which ought to be adminstered only under medical supervision, and by medical prescription, as this gentleman says, it would have been fair criticism on a *matter of public interest* without question, I think. No jury would have failed to find it so, but if you choose to say this Mr. Tucker is guilty of fraud because he has sold it at *such a price*, *because* he has been supplying the public with poison and robbing them, that is not a fair criticism on a matter of public interest.

Mr. Eldon Bankes: If *your lordship will pardon* me, *I* am fully aware of your lordship's point.

Mr. Justice Ridley: You said he has been guilty of fraud, robbery, and poison.

Mr. Eldon Bankes: I am fully aware of your lordship's point; I intend to deal with it, but I ask to give my evidence.

Mr. Justice Ridley: I really did not wish to discuss the matter at this moment. It arose in this way; we go on with this point which keeps off the libel.

Mr. Eldon Bankes: I think if my friend had thought the evidence was not admissible he would have objected to it, but he feels that it is relevant and I ask that it should be taken without objection.

Mr. Justice Ridley: I imagine it may be relevant to the issue in case there be any case for the jury to support what you claim—namely, that this is a fair criticism on a matter *of public interest*. My great doubt at present is whether there is any evidence to go to the jury at all on your side.

Mr. Eldon Bankes: Your lordship I am sure will defer your decision upon that.

Mr. Justice Ridley: You have not justified it and you ought to have done; that is the long and the short of it.

Mr. Smith: Were you in court while Lord Ashburnham was giving evidence?—No, I was only here yesterday afternoon from 3 o'clock to 4 o'clock.

His lordship said *that* he was recommended Tucker's specific by Dr. Mitchell Bruce?—Yes.

I want you to tell me about Dr. Mitchell Bruce. Is he a competent physician?—I am not here to express any opinion upon any of my professional colleagues.

I quite see your difficulty. You would not agree with the advice which he gave?—I should not personally prescribe Tucker's remedy for an asthmatic patient.

Assuming that Dr. Mitchell Bruce recommended it to Lord Ashburnham without any arrangement at all to personally supervise its use your view would be that that was very wrong?

Mr. Eldon Bankes: We have not any evidence that that is so.

Mr. Smith: Yes, we have.

Mr. Eldon Bankes: Lord Ashburnham said that he was a patient of Dr. Bruce. He recommended it and presumably, therefore, if he was a patient he would continue to consult him while he was using it.

Mr. Smith: As a matter of fact the only statement made by Lord Ashburnham was that he was recommended to use

Was it then that for the first time you told THE LANCET people or their representative that you had said "Gentlemen, the remedy is a fraud"?—If I did tell them so, it must have been the first time. Of course, I had sent this paper with this document.

That is immaterial to the question which I am asking you: It appears by the pleadings which are before the Court that at some time between the 9th July and the 21st November the defendants decided to allege that you had said, "Gentlemen, the remedy is a fraud." Did they so decide, as far as you are aware, upon a statement which you then made to them?—I could not say; I do not know.

Did you see them or their solicitor?—Their solicitor saw me.

Was that some time in the summer or autumn of last year?—Yes, it might have been then, but I really cannot remember the date.

Did you and he read over the newspaper extract together.—Yes, I believe it was produced.

Was there any discussion between you about it and about the possible view that what you appeared by the newspaper report to have attacked was the Government system, whereas the defendants had charged a personal fraud against Mr. Tucker? Was there some discussion between you about that?—I cannot remember that.

I wish you would charge your memory about that. You did discuss the newspaper report, did you not?—Yes, I can remember that being produced.

Did you also discuss the fact that THE LANCET had charged the plaintiff with personal fraud?—I think it is very possible that on that occasion—as I say, I cannot remember details—I probably might have said that it was a fraud, but I intended the word "fraud" as against the so-called Tucker remedy, and not as against the use of the Government stamps.

So that, although the newspaper might have led a reader to suppose you had been attacking the Government system, when the discussion took place and THE LANCET were being challenged with having accused the plaintiff of personal fraud you said you thought it was a fraud.—Yes; that I used the word "fraud" as against the Tucker cure and not as against the use of the Government stamp.

So the reporter of the other paper of which you have an extract before you was quite mistaken in supposing that you were attacking the Government system?—Yes, he was entirely wrong.

And Mr. Norman, the local reporter who was here in the box yesterday, was quite wrong about it, too.

Mr. ELDON BANKES: Have you got his report?

Mr. DUKE: I have not his report of the evidence.

The WITNESS: I have not heard any report of the evidence.

Mr. ELDON BANKES: I have had three reports and they all disagree.

Mr. DUKE: This is what he said: "The coroner never to my recollection said that Tucker's dealing or remedy was a fraud. I should have recollected it; it would have been good copy."

Mr. Justice RIDLEY: He said he had no distinct recollection.

Mr. ELDON BANKES: His report does not say anything about fraud.

Mr. DUKE: He says: "I should have reported the fact if the words had been used about Tucker."

You, of course, sitting in your court as coroner are privileged to attack people's character without hearing them?—It is my duty as a coroner if I think occasion occurs to give expression to that view to the gentlemen of the jury.

I follow what you say, that you regard yourself as having a duty?—I do most certainly.

With regard to persons who are not before you?—If the occasion warrants, certainly.

If you think so?—Yes.

You know that you are privileged in whatever language you use in what you regard as the exercise of that duty?—I believe I am. I swore when I was first coroner that I would do my duty to the public, and I consider that is my duty.

I daresay you also know that a newspaper does not occupy the same position?—No, I presume they have not the same privilege that the coroner would have.

They have not that immunity.

Mr. Justice RIDLEY: I hope not, indeed. (To the witness.) You are not liable at all; you are quite right.—I believe any judge is not liable, my lord.

No, not at all.—A coroner is a judge of record.

Mr. Justice RIDLEY: I think you are perfectly right.

Mr. DUKE: Do you not know in the ordinary course that before you are going to condemn a man you call him up and say: "I am going to criticise your conduct; what have you to say about it?" Do you know that?—In this case I was quite satisfied——

Never mind this case. Do you know that—that in an ordinary case before a judge is going to condemn a man, as you say, for fraud he has him before him and tells him and hears what he has to say? Do you know that?—Yes, if there is occasion for it.

But in your court you did not consider it necessary?—No, I did not; I was quite satisfied with the evidence before me.

Had you ever analysed this specific?—No, I never have, but I knew what was in it according to the books——

We will see about that. Had you ever received an analysis of it?—I had a qualitative analysis of it.

Was it a qualitative analysis which so far as constituents were concerned shows some such constituents as are spoken of in the evidence here?—Yes, both atropine and cocaine.

That you had seen and that you believed?—Yes, I knew well about that some time before.

That is, that you had become aware of it as a doctor?—Yes, or as a coroner.

I will ask you which it was?—I happen to be a medical coroner—both ways.

I am quite aware that you are a medical coroner. Do you suggest to the jury that in any inquest which you had ever conducted any evidence was ever given about this specific until this case of Cushing?—Yes, the widow told me that her husband——

Mr. ELDON BANKES: He misunderstands the question.

Mr. DUKE: Let me put my question again to you. Do you suggest that at any inquest you ever conducted except the Cushing inquest any evidence was given about this specific?—No, I cannot remember that any was.

Mr. Justice RIDLEY: It is your knowledge as a doctor then?—Yes.

Mr. DUKE: Had you known anybody who had ever used this specific?—At that time I cannot say that I had.

That is all I asked you. With regard to Oppenheimer's list did you know that Oppenheimer had produced and put upon the market an asthma specific in imitation of this specific?—I had never heard so until I heard so in this court.

But did you know that some eminent English drug firm had produced and put upon the market an asthma specific in imitation of Dr. Tucker's asthma specific?—No; I never knew such was the case until I heard it in this court.

You know it now?—Yes; I do.

Does it surprise you at all?—No; I cannot say it surprises me.

You regard it, I take it, as quite a proper thing that Oppenheimer's should produce this specific and sell it wholesale at 3s. 6d. an ounce and describe it as an asthma specific, and say that it produced the effects which the American specific produces? You regard that as a natural thing?—I have never said so.

Do you?—No; I do not if, as you say, it is described as a specific. I take "specific" in the English meaning—I mean very much the same as "cure."

Quite?—If they say they profess to cure and to cure indiscriminately, and throw this broadcast about to all those who take it without being seen by a medical man or under the supervision of a medical man, then I should say it is very wrong.

Mr. Justice RIDLEY: Is it a fraud?—I should say it was fraudulent.

Mr. DUKE: Leaving out all those aggravating circumstances which you have mentioned, do you mind dealing with the plain statement of Oppenheimer that this is a specific for asthma? Do you want to say that that is fraudulent too?—I say so if they profess to cure asthma. In my opinion real spasmodic asthma is an incurable disease and I should say it is distinctly fraudulent—that is unless, of course, under medical supervision. I do not know what those people do—whether they sell it to medical men or how it is dispensed.

Then the person who would be licensed to say that he applied a specific for asthma must be a medical man?—I think it should be given under the supervision of a medical man certainly, otherwise it would be most dangerous to the public.

If a medical man has ever described it as a specific for cocaine and atropine, which seems to suit him. He is being now fed on cocaine and atropine I take it instead of arsenic.

Mr. Justice RIDLEY: Do you think that is a fair answer really?—No, I am simply arguing because he has already said he has been fed on arsenic.

Mr. Justice RIDLEY: He only used that phrase because it was put to him.

Mr. ELDON BANKES: No, he used it playfully; it was not put to him.

Mr. SMITH: You were only speaking in play too, were you not?

The WITNESS: I did not mean that, of course.

Mr. SMITH: Just for a moment to get a serious explanation that would seem to show that you have *here* a case of a sensible professional man to whom the doctors have failed to give any substantial relief.—I should like to know what the doctors have done and what the treatment was.

Of course there was every opportunity to ask him, and my learned friend very wisely did *not* take it. You must assume that the doctors gave him *proper* advice.—He refers back a very long time to Sir William Jenner's time when the treatment of asthma was not so well known as it is now.

He did not say that he ended with Dr. Jenner's advice, and it is reasonable to assume that he was given competent advice by qualified medical practitioners?—Yes.

Taking the case of a man like that—and the jury heard his evidence—assuming he did fail to get relief from qualified medical practitioners, you do not seriously suggest to my lord and the jury that he is unwise to use a specific from which he derives constant relief which has done him *no harm up to now*. That is your view, of course, if I understand it?—That he is unwise to use it? How often does he use it?

Mr. ELDON BANKES: He used an ounce in 12 or 18 months.

Mr. Justice RIDLEY: "I used it *formerly* as *frequently* as I wanted it."

Mr. ELDON BANKES: But he said he exhausted one ounce in 12 or 18 months; that is a very infrequent use, of course.

Mr. Justice RIDLEY: "Perhaps three or four times in half an hour."

Mr. ELDON BANKES: Yes; whenever he had an attack; but he only used an ounce in 12 or 18 months.

The WITNESS: I should assume in that particular case that not very much harm has come of it. Whether it will in the course of time of course I do not know.

That is a grudging testimonial. Would not you go further and say that considerable good seems to have resulted from it?—He has relieved the symptoms, but apparently he is not cured.

He never was cured before and he did not get relief before?—He is not cured now, is he?

No, but he gets relief?—But that has not cured it. You assume that it is a cure.

As a matter of fact I think he did say that the asthma began to go. "Since using this specific I can always sleep."

Mr. Justice RIDLEY: "I hardly require it at all now."

Mr. SMITH: The cocaine habit is making very slow progress in that case, is it not?—Yes.

Mr. ELDON BANKES: Do deal with it seriously. We do not suggest that he had the cocaine habit.

Mr. SMITH: It is so difficult to treat it seriously.

Mr. Justice RIDLEY: Dr. Tilley's evidence goes to this extent that it is almost necessary that everybody should have the cocaine habit if it is used in such quantities.

Mr. ELDON BANKES: It is all a question of degree. I hoped I might save time by agreeing with my learned friend. I do not suggest that any appreciable harm would come to a man who used an ounce of this in 12 or or 18 months. It may be unwise, but it would give him relief I agree, and I agree that no appreciable harm would come to a person who used it in those quantities, and as long as a person confines himself to those quantities no harm would come to him.

Mr Justice RIDLEY: I do not think Dr. Tilley agrees with you.

Mr. ELDON BANKES: I do not know whether he does or not.

Mr. Justice RIDLEY: He said that it was not safe to use it in these doses at all.

The WITNESS: In what doses, my lord?

In doses such as in this specific?—I do not remember having said so.

"It is not safe to use indiscriminately, even in small doses."—Indiscriminately, yes.

Mr. SMITH: What does that complication mean?—It means that a confirmed asthmatic will carry that with him and use it every ten minutes or quarter of an hour or half an hour during the day, and my whole point is that with a person who used it so frequently as that and so often this drug must be acting upon him deleteriously. With regard to a person taking it once now and again, I am not prepared to say that it is going to do him irreparable harm.

Mr. Justice RIDLEY: You also said this: "I consider that this specific used for a certain amount of time is calculated to produce the cocaine habit."—I think it does because I have seen it.

Mr. SMITH: Do you accept the view that an ounce used in a year or 18 months could be used with impunity?—Not by some patients. I do not think some patients could use that with impunity.

Taking the case of a patient like Mr. Bateson, who finds he can use it with impunity after years of experience, who gets alleviation from these attacks, and who finds he has to use it less and less, do you say it is unwise of him to use this specific?—No, because if he goes on using it less and less he ceases to use it at all.

And he has the advantage of being cured?—It will be the first case I have known of a cure from it.

One lives and learns.

Mr. Justice RIDLEY: A witness was called yesterday, Mrs. Pimm, and I do not think she has much the matter with her now.

Mr. SMITH: No, she is very robust.

Mr. Justice RIDLEY (to the witness): *Did you see her?*—No, I did not.

Mr. SMITH: I suppose the appearance of external robust health is quite compatible with the cocaine habit. One may look very healthy and yet be addicted to cocaine, I suppose?—In the early stages of the habit, yes.

To deal with Mr. Bateson's case I gather that you agree that if the necessity for using the specific occurs less and less and the attacks grow fewer he was wise to use it?—If he used it with discretion, yes.

You cannot use it with more discretion than by using less of it, according to your view?—No.

Then let us have it without any qualification. Mr. Bateson is quite right to use it?—Mr. Bateson might be.

And you would say as it is right for Mr. Bateson to use it Mr. Tucker has done a service, at least to Mr. Bateson, by putting it on the English market?—At least to Mr. Bateson.

At any rate he has benefited somebody. Now let us take Mrs Pimm's case. Were you in court when Mrs. Pimm was called?—No.

She was a lady who described herself by saying graphically that she was a perfect wreck and could not do any work at the time when she was first introduced to Tucker's specific. I think she uses it less, too, but my lord will tell me if I am wrong there.

Mr. Justice RIDLEY: There is not so complete an account of her case as there is of the others and she was not cross-examined. I think.

Mr. SMITH: No, I think she was not.

Mr. Justice RIDLEY: "I have had asthma since 1891 and was quite a wreck five years ago. The doctor gave me no relief. I tried *everything* I could think of. Somebody recommended this specific four or five years ago and I got it on trial and paid for it. It gave me relief instantly and I have never been laid up since. I have never acquired the cocaine habit."

Mr. SMITH: There is one sentence which your lordship did not take, that she always had doctors in her house before.

Mr. Justice RIDLEY (to the witness): You did not see her?—No.

Mr. Justice RIDLEY: The chief part of her evidence was her appearance, I think?

Mr. SMITH: Yes, her robustness.

Mr. Justice RIDLEY: I never saw a more healthy-looking person.

Mr. SMITH (to the witness): There again, if she had to take *less*——?—If it will save time, I am not prepared to deny that you might bring plenty of people whom it has relieved and whom it will continue to relieve, but that does not alter my opinion that the indiscriminate prescribing or ordering of that is an unwise procedure.

You do not put it higher than that; you simply say that it is unwise?—I think it is a fraud.

You think it is a fraud?—Oh, yes.

Have you had submitted to you the instructions which Dr. Tucker sends out and the pamphlet explaining the treatment?—Yes, I know them generally.

Have you also had submitted to you the analysis of the mixture?—I have.

Do you find that the analysis shows that the liquid contains cocaine and atropine and sodium nitrite?—Yes.

Are you familiar with the nature and effect of those drugs?—Yes, I am.

Are they known drugs in medical science?—Very well known, yes.

Take, for instance, cocaine. What is the nature and effect of cocaine?—It has a localised effect upon any membrane or absorbent surface to which it is applied and it has a general effect.

Is its effect cumulative?—The effects are cumulative, yes.

Is it in its nature a dangerous drug?—Yes; it is a dangerous drug—that is, a very small dose may be fatal.

In certain diseases is it a drug which it is not proper to use?—Yes; it would only be used for very few diseases.

May I take the case, for instance, of heart disease?—It would have to be used with very great caution. It would be very rarely used in heart disease.

Take kidney disease.—It would be rather a dangerous remedy in kidney disease.

And take consumption—phthisis. That is the third one which has been mentioned.—It would only be used in consumption as a local application for the throat affection.

Do all those three diseases—heart disease, kidney disease, and some forms of consumption—present symptoms sometimes which are very difficult to distinguish from the symptoms of asthma?—I do not think there should be any difficulty.

I do not mean for a doctor.—I do not think a doctor should find any difficulty.

Would a patient very often mistake them?—It is quite possible; yes.

Do you find in your practice that sometimes asthma is associated with heart disease or associated with kidney disease or associated with consumption in the same patients?—The symptoms of asthma are so associated sometimes.

In your opinion is it safe to sell any specific containing cocaine indiscriminately?—I should say it was unsafe.

Have you read Mr. Tucker's instructions to patients how to use his specific?—Yes.

Have you noticed that there is no warning that it is to be used with caution?—I noticed that particularly.

Is asthma a very distressing complaint?—Very distressing.

And if a patient found something which would relieve the attacks, he would be very likely to use whatever it was very frequently, would he not?—I should say so.

Having regard to those conditions, do you think that the continued use of this specific in certain cases is likely to be injurious?—Yes, I think so.

In what way would it produce injury?—It would produce injury to the nervous system and weaken the heart function.

Are you familiar with the cocaine habit?—I have seen a case or two of it; I am not very familiar with it.

With regard to cocaine, I think one witness has used the expression that it is a seductive habit?—Yes.

Is it a habit easily acquired?—Yes.

Does it differ with different patients? Are some patients more susceptible than others?—Yes.

And some patients take safely quantities which to other people would be extremely unsafe?—I should say so.

Do you say that with regard to symptoms likely to be produced?—People vary very much in their sensitiveness to the drug, and they vary very much in their disposition to take drugs like cocaine and morphia, and so on.

Do you think the frequent and repeated use of this specific over a long period is likely to produce the cocaine habit?

Mr. DUKE: That is a very leading question.

Mr. ELDON BANKES: But I must put it.

Mr. Justice RIDLEY: He says he has only seen a case or two.

Mr. ELDON BANKES: Can you form an opinion from your general experience?—Certainly. In any particular person inclined to habits of that kind it would be likely to produce the cocaine habit.

Cross-examined by Mr. DUKE.—You were called in to this case, I suppose, merely as an eminent medical man after this action had been instituted?—I presume so.

Mr. Justice RIDLEY: Is that so?

Mr. DUKE: You say you presume so. What I mean is, had you heard anything of this matter until after the action?—No.

We have not seen the author of this publication. Do you know who the man was who wrote the statements complained of?—I have no knowledge of it at all.

I think what you have told us has been chiefly with regard to cocaine. Is it the fact that consumptive people may suffer from asthma, or not?—It is not impossible for a consumptive patient to have asthma.

You say it is not impossible?—It is not very common in fact.

It is a great deal more trying and distressing for a consumptive patient to have asthma than it is in the case of a person who was free from phthisis?—I cannot say about that.

You have no opinion about that?—Asthma is a very painful affection in whomsoever it occurs.

I should have thought it would be much more painful and distressing in the case of a person who had a deadly disease?—They are not very commonly combined.

In the case of heart disease, have you found asthma combined with heart disease?—Not through asthma as a rule, except that the heart, towards the end of the asthmatic illness, gets disabled and in that way complicates the asthma.

Is not one effect of asthma to steadily affect the action of the heart?—The effect of asthma is to weaken the action of the heart.

If you found a person whose health was steadily degenerating from asthma who by any sort of remedy was relieved from severe attacks of asthma and thereupon experienced a good recovery of general health, that would indicate, would it not, that the heart was getting stronger?—That is rather a complex question. Will you put it again?

Mr. Justice RIDLEY: I think what counsel means is this: If you relieve the asthma would you relieve the heart?—The remedy used for the asthma deteriorates the heart.

Mr. DUKE: Suppose you found a person getting ill as regards general health, and the asthma relieved and the person getting better, does not that show an improved condition of the heart?—It shows an improved condition of the asthma and a relieved condition of the heart.

Mr. Justice RIDLEY: We have had evidence of that about General Stewart.

Mr. DUKE: And by General Lane.

Mr. Justice RIDLEY: Yes.

Mr. DUKE: Will you tell me whether the symptoms of asthma, which, as I understand, are simulated by some of the diseases you have mentioned, are relieved by any treatment of asthma?—It is very possible that any spasmodic might relieve such symptoms.

I rather gathered that that is a different view from what Dr. Willcox gave us yesterday; but that is your view?—Yes.

It would relieve what I call simulated symptoms of asthma arising from organic disease?—It may be relieved by any spasmodics.

Had you yourself become aware of this remedy?—Oh, yes.

Mr. Justice RIDLEY: When did you become aware of it?—In the course of my practice I have met with patients who have used Tucker's cure.

Mr. DUKE: Have they gone on using it?—Some of them have.

You did not think it necessary peremptorily to stop them, or anything of that kind?—I have felt it sometimes necessary to stop the use; in other cases I have given very serious cautions as to the excessive use of the remedy.

At any rate, patients of your own have gone on using the specific?—I have no doubt; I do not know.

We have had a Mr. Pickmeyer here yesterday who had been a patient of yours.—I have no recollection of his name. It is very possible.

Mr. Travers Pickmeyer?—I may have seen Mr. Travers Pickmeyer. I see so many patients that I cannot recollect.

I quite follow; but it may recall it to your mind if I say that this was a gentleman who was sent to Mont d'Or.—I have sent a good many people to Mont d'Or.

Asthmatic people?—Yes.

Mr. Pickmeyer was sent to Mont d'Or; he came back from Mont d'Or not benefited, and then was referred back to advice at Harrogate. He told us yesterday that he failed to get any sort of relief from the medical treatment he had had?—Yes.

Mr. ELDON BANKES: We say so. We may be right or we may be wrong, but if we formed the opinion that he is claiming a cure in the full sense, we are justified in saying that a person is committing a fraud on the public if he sends out a medicine with that statement when he himself knows that it will not cure.

Mr. Justice RIDLEY: But that is entirely a travesty of the evidence in this case.

Mr. ELDON BANKES: I am sorry I do not assist; I thought I might save time.

Mr. Justice RIDLEY: You do not help me at all in this case. I am trying to keep to the evidence and I will not be taken from it. (To the witness): You say it is a fraud because you disagree with him; nothing more or less.—I do not, pardon me, my lord. May I express again what I believe?. I think it is a fraud for a person to send out any drug or medicine of any kind and to lead people by a pamphlet such as this to believe that they can be cured when he himself allows that he cannot cure and does not cure.

He does not say that in the pamphlet at all.—I think the plaintiff gave evidence here that he agreed they did not cure and did not pretend to.

Mr. SMITH: And you would say in the same way that it was fraud even if he could cure each successive attack of asthma?—I do not follow you.

I should have thought it was very simple.—To you, perhaps.

Even if it is a fact that he can cure each successive attack of asthma although he cannot remove the liability to asthma you would say it is a fraud?—My point is that in using the word "cure" here I assume he uses it in the sense that the public would accept it—that is to say, an absolute cure of the disease.

You do not follow me in the least. There are two things; one is to cure all liability to asthma and the other is to cure specific attacks as they develop in the person liable to asthma. Do you appreciate that distinction?—Yes.

Supposing it to be the case that Mr. Tucker can in fact cure specific attacks of asthma, although he cannot guarantee that there will not be a recurrence, do you still tell the jury that he is fraudulent?—How do you speak of a "cure" and in the next breath say "recurrence"? If you "cure" a cancer and it returns——

Have you ever heard of such a thing as curing a cold?

Mr. Justice RIDLEY: Are you aware that this pamphlet was not sent out?—I was not aware of that.

This thing is not sent out with the instructions at all; you seem to treat it as though it were.

Mr. ELDON BANKES: I think it is sent out.

Mr. Justice RIDLEY: No, not until it is asked for.

Mr. ELDON BANKES: His answer was that he sent out the pamphlet to anybody who made any inquiry.

Mr. Justice RIDLEY: Yes.

Mr. ELDON BANKES: Of course, the persons who make the inquiries are the persons who afterwards inquire for the treatment.

Mr. SMITH: You can imagine, I suppose, *curing a cold* being perfectly consistent with the person whose cold is cured having another in *six months* or three months?—Speaking of a cold, yes; but I think the term "cure" is not what the public would take it to be in that case.

You shall have the opportunity of explaining it in a moment, but so far as the reasonableness of using the term is concerned you would agree that a man *may* say he can cure a cold and yet the man *may* have another in six months?—I quite agree.

Why cannot a man say with equal reasonableness, "I cure and relieve a specific attack of asthma, although I cannot prevent the man who is constitutionally liable to *asthma* getting future attacks?—Because in one of these pamphlets he says, "Not only relieve, but cure," indicating some difference between the two.

Will you point it out?—It is here somewhere. I cannot tell you the page, but we read it just now.

Mr. Justice RIDLEY: It is just after the long paragraph which you have not read which describes the operation of the thing. He says: "We now offer to suffering humanity the result of 20 years' experience, which has finally worked out a cure for asthma and hay fever as well as all other catarrhal diseases of the air passages."

Mr. SMITH: Is it possible that you do not see a much more reasonable explanation of using the word "relieve" and "cure"?—No.

Let me see if I can suggest it to you, although I have not the advantage of your scientific experience. Does it not suggest to you that to "relieve" an attack may be to assuage it and to make it less severe, and that a further stage in the alleviation is the "cure" of that specific attack? Does not that seem to you a perfectly reasonable distinction?—*I am bound to say* that if a man told me I had cancer and he would cure it I should understand by the term "cure" that I need not look for a recurrence.

Is your serious suggestion to the jury that the case of cancer is more analogous to the case of asthma than a cold in which you agreed to my description?—No; I think I agree with you there that a cold is more analogous than the case of cancer.

Do not let us complicate it by illustrations that do not apply at all. A cold being more analogous to asthma you will agree that if it be the fact that Mr. Tucker can cure specific attacks of asthma—you follow me?—Yes.—You do not object to the use of the word "cure" so guarded?—Yes, I do. I think you ought to say "relieve" specific attacks.

It comes to this, that even if Mr. Tucker can cure specific attacks of asthma you object to him telling the public so?—No, I do not.

Then you do not object to his telling the public that he can cure specific attacks of asthma?—I do, because he cannot.

You will not follow the hypothesis. I based my question upon a hypothesis. Assuming it to be the fact that the various witnesses who have spoken of it are right in saying that specific attacks of asthma can be cured by *this*, you would not object to Mr. Tucker saying that he could cure them?—I should, certainly, publishing it in this particular form.

You do not assist me by telling me what the words are.—It is simply the use of the words and the application of commonsense to the ordinary English language. If a man says to me, "I can relieve your attack of asthma," I understand what he means, but if he says, "I can cure it by this treatment," I go away with the idea that he has done something, and that I need not look for a recurrence. I cannot explain it better than that.

You cannot understand Dr. Thomas Clark saying that though it contained cocaine and atropine it is in such small quantities that it has no ill-effect, even though he has such a lot of it in his system? You would say he is wrong and you are right on the broad principle of common sense.—I should say he might come across cases where that small amount of cocaine might produce damage to the patient, or so shroud the symptoms that the patient could not get proper relief.

Although you have no personal experience of it you prefer your opinion to his?—Because many patients who have been using it have applied to me and have said——

We cannot have what they said to you.

Mr. ELDON BANKES: You asked the question.

Mr. SMITH: I have not asked that question, and Dr. Tilley knows I have not.

You know Oppenheimer's mixture, I suppose?—Yes.

Have you seen this in the book published by Oppenheimer: "Many inquiries from important medical men having *reached us* regarding a certain preparation for asthma recommended by an American doctor, we introduced our Neboline compound, No. 21, which is similar in every respect to the preparation in question and which from the reception accorded to it seems to meet all requirements." Then there is this note in italics: "Practically a specific for asthma." Have you seen that note?—I see it now.

You have not seen it before?—I may have seen it a year or two ago.

Is that another fraud?—Does it promise to cure asthma here?

No, but it is just the same thing.—He does not say it is a specific for the cure of asthma.

You think it means a specific for the aggravation of asthma?—No; possibly for the relief of it.

Mr. Justice RIDLEY: Are you honestly giving that evidence?—I think so.

Mr. SMITH: Do you think that is a good distinction? Practically a specific for the relief of asthma. I do not see why we should allow——

If it had been a specific for the cure of asthma you would say, of course, that was fraudulent?—I should have thought it was distinctly a fraud, absolutely.

They are very respectable people, are they not?—Yes.

any directions or cautions as to how frequently it may be used with safety they overdo it and they suffer, and they suffer particularly with regard to their hearts. Their hearts will naturally tend to become overstrained towards the end of the disease and become more easily affected by the strain.

Further cross-examined by Mr. DUKE.—Will you tell me when was the first time any person who had used the Tucker specific came to you?—I am afraid I could not tell you that; it would be some years ago.

When was the last time?—I daresay it may be within a few weeks or a few months.

Do you know one or the other?—No; I could not tell you.

Have you any positive recollection of seeing any person who has used the Tucker specific during the last 12 months?—Yes, I think I have.

Is it one or more?—I think I have had several.

Have you any distinct recollection of any during the last 12 months?—Well, I saw a patient about ten days ago and I saw a patient, it may be, three weeks ago.

Both of whom had used the Tucker specific?—Yes.

Are both of them still using it?—One of them had relinquished the remedy because she found it did not do her any good and she flew to some other specific. She had used Tucker and relinquished it.

Because she found it had not done her any good?—She had used different remedies at different times.

She did not go on with Tucker?—I think not.

She did not find it so overwhelmingly successful that she went on with it?—Quite so.

In the other case, did you permit that patient to go on using it?—I cannot say in that particular case. I certainly was aware that the patient was using the drug and I said, "You must use it with caution."

That is your recollection; that you were aware the patient was using the Tucker specific and you said, "You must use it with caution"?—Use it with caution.

Have you any recollection of any other case which you can state to the jury except those two cases of use among your patients of the Tucker specific?—Yes, I have.

Will you give me the case before that?—It was a case a few months ago I saw who had been using Tucker very considerably and got into the way of using it too much and her husband consulted a throat specialist about the case and by his advice she had relinquished the drug, and she was the better for it.

Was she suffering from asthma?—She was suffering from asthma.

Apparently she had no difficulty in giving it up?—I cannot tell you. I think she had great difficulty in giving it up.

But she did relinquish it?—She had the courage to relinquish it.

Do you know anything as to the moral circumstances, whether there was courage or effort? She found it did not suit her?—Her husband found it did not suit her, consulted a specialist, and induced her to relinquish it.

Have you seen other cases of the same kind?—Yes, from time to time.

Further re-examined by Mr. ELDON BANKES.—When you say this lady's husband found it did not suit, how do you mean, that the specific did not suit her or that she was using it to an extreme?—She was using it to excess.

And it was in consequence of that that she was taken to the doctor?—I cannot say. She was taken to the doctor and he found she was using this remedy too much and induced her to relinquish it.

Sir LAUDER BRUNTON, *examined by* Mr. HUGH FRASER.—You are a Doctor of Medicine and a Doctor of Science, and I think you are a Doctor of Laws of Edinburgh University, an Honorary Doctor of Laws of Aberdeen, a Fellow of the Royal College of Physicians, a Fellow of the Royal Society, and a Fellow and Member of various other societies, and the author of numerous medical works?—Yes.

Has the chief study of your life been the action of drugs and their application as remedies of disease?—Yes.

You are familiar, of course, with the nature of cocaine?—I am.

Will you just state shortly the nature and effect of cocaine as a drug?

Mr. DUKE: I have not asked that question in cross-examination about the nature and effect of cocaine. I do not want to stop my learned friend from giving evidence about the nature and effect of cocaine, but I think it would shorten it.

Mr. ELDON BANKES: It is very difficult to ask the exact question, but if you do not object to it we will not prolong the examination.

Mr. DUKE: I only wished that the evidence should not be prolonged.

Mr. ELDON BANKES: We shall not prolong it.

Mr. Justice RIDLEY: It is only a question of degree. I believe that it is recognised that cocaine is in the list of poisons, but poisons range over the whole Pharmacopœia; nearly everything is a poison if you take enough of it.

Mr. FRASER: Is the effect of cocaine as a drug cumulative or not; what do you say about that?—That depends upon the meaning you take to the word "cumulative." If you mean by "cumulative" that the drug accumulates in the system I say No, but if you mean that the effects produced by the drug are cumulative I say Yes. The drug passes out, but the effects that it produces during its application remain behind. Shall I explain that a little more fully?

Please.—Cocaine is a substance that only medical men as a rule are acquainted with, but everyone knows the effect of alcohol. A man drinks a glass of whisky; the whisky passes out but the effect of the whisky remains, and if he goes on nipping, nipping whisky after whisky all day long, although the whisky has passed out of him, the effect remains with that man. The same is the effect of cocaine. Small doses of cocaine *per se* pass out, but the effect they produce remains.

Do you say it is a proper drug to administer, even in small quantities, without caution?—No.

Do you say that it is proper to administer it at all except under medical advice and medical supervision?—It is unsafe. I should therefore say it is improper.

Will you tell me, please, why you say it is unsafe?—Because the effect of cocaine differs so much in different individuals that one man may take a large dose of it and it may produce no effect, and another man may take a very small dose of it and produce a great and unexpected effect. It is the same way, really, with alcohol. One glass of whisky may make a man drunk, and another man may take a dozen whiskies in the course of the day and they will produce no apparent effect. It is just the same with cocaine.

Would it have to be used with great caution if anybody were suffering from heart disease?—It should be used with caution in all cases, and especially in the case of heart disease.

Or in the case of kidney disease?—There also it should used with caution.

Or in the case of consumption?—In all those cases, the reason being that cocaine has a certain tendency to weaken the heart, and in all those diseases that is a condition to be avoided.

May a person suffering from any one of those diseases have asthmatic symptoms which he, the patient himself, might simply think indicated asthma and nothing else?—Yes.

I think you have had submitted to you the analysis of Tucker's specific, and I think also you have seen the instructions issued with the specific?—Yes.

Do you say that taking the specific in accordance with those instructions is a safe thing to do or not?—For a large number of people it would be quite safe, but there are certain persons who would be particularly susceptible to cocaine, and for those it would be unsafe. If I may revert again to my illustration of alcohol as a well-known drug, there are millions of people who take alcohol all their lives long, and in large quantities, and are not a bit the worse, but there are certain persons to whom alcohol is a poison, and a very small quantity is enough to do them serious damage and to bring on the alcoholic habit; so it is with cocaine.

Are you familiar with what is known as the cocaine habit?—Familiar in so far as I have had to acquaint myself with the observations of others in order to lecture upon it at St. Bartholomew's Hospital; I am not acquainted with it personally.

Mr. Justice RIDLEY: You have not met anyone who had it?—I have met one man who, I believe, had it, but it was only after his death that I learnt about it. I did not know of it during his life.

Mr. FRASER: Would this Tucker's specific cure asthma or not?

Mr. DUKE: I object to evidence in chief upon this matter.

specific?—Yes. What was said about that?—The instructions were handed to me with an illustration of Dr. Tucker's atomiser.

Is that the paper, or a similar paper (handing document to the witness)?—It is a long time ago, over a year ago, but so far as I can remember there was a similar paper with a picture——

I think this is the actual one but I am not sure. (Document handed to the witness). Perhaps you will recognise it?—I distinctly recognise this one with "Dr. Tucker's asthma specific" upon it, with the words "asthma, hay fever, bronchitis, catarrh," with a picture of the apparatus, and with the address, "Onaway, Half Moon-lane, Herne Hill, S.E. All correspondence should be addressed to A. Q. Tucker, General Manager."

Is that the document handed to you or a similar one?—It is a long time since I have seen it.

To the best of your recollection I mean?—To the best of my recollection.

Mr. Justice RIDLEY: Had it the name and address?

Mr. ELDON BANKES: Had it a picture of a man using the atomiser?—I would not be positive about that, because I have not seen it for so many months; I am sure about the front one. It was a paper, *so far as I can* remember, similar.

Mr. Justice RIDLEY: I have the paper signed by Cushing, or at least the paper *filled* up by Cushing, if it is any good at all. Perhaps it would assist you to look at that. (Handing same to the witness.)—I have not seen this paper as filled in.

Mr. ELDON BANKES: He did not have the questions; it was the instructions.

To the best of your belief it was that or something similar?—Yes.

Was anything said about the deceased man having used this?—Yes; it was said that he had used it for some time, both the atomiser and the fluid used with it. Evidence was given also as regards the price paid.

Do you remember what was said about the price?—It was said that the price paid was 3 guineas for the atomiser and 8*s.* an ounce for the fluid. I have since heard that £3 was the right price.

I am speaking now of the evidence before you?—That was the evidence, 3 guineas for the atomiser and 8*s.* an ounce for the fluid.

When you heard that evidence did you make any observation yourself about this thing?—I did.

What was it you said?—In reference to the atomiser and the fluid—that is the treatment—I said that I considered it was a quack remedy, and I also said that it was a fraud.

That is what you said in open court at the inquest?—I did.

I am not saying for a moment whether you were right or wrong in what you said or thought, but did you think it was a matter which required ——

Mr. DUKE: I object to what the coroner thought. What he said is evidence, of course.

Mr. Justice RIDLEY: What he said must be evidence in this case, because it is material to the issue.

Mr. ELDON BANKES: Very well, I will deal with that.

Mr. Justice RIDLEY: But I do not think that what he thinks is evidence.

The WITNESS: I will give my reasons, my lord, for using those two words.

Mr. ELDON BANKES: I think you did not give any reasons in court, did you? I want all you said, as far as you remember, in open court about it.—I cannot remember at this lapse of time—it is over a year ago—whether I gave my reasons. I know what was in my mind at the time.

Of course, I cannot have it unless you expressed it, but you have told us, in fact, what you said in open court.—Yes.

Cross-examined by Mr. DUKE.—Did you send, or cause your clerk to send to THE LANCET office a newspaper report of the inquest?—I did.

I call for it. Did you send it because it is an accurate account of what had taken place?—I sent it to the editor of THE LANCET to do what he liked with it, because I considered it a matter of interest to the profession and to the readers generally of THE LANCET.

Now, would you mind answering my question: Did you send it as an accurate report of what had taken place.—I did.

Will you look at it? (Handing same to the witness.)

Mr. Justice RIDLEY: Is that the one you showed Norman yesterday?

Mr. ELDON BANKES: No, this is not the one which was shown to the reporter. This is the *Morning Advertiser*.

Mr. DUKE: This is the one which was sent; I do not care which it is; I do not think it is the *Morning Advertiser*.

Mr. ELDON BANKES: Yes, it is a cutting from the *Morning Advertiser*.

Mr. DUKE: I am not sure about that.

Mr. Justice RIDLEY (to the witness): What do you say about it?—This is the one I sent.

Is it an accurate report?—As far as it goes. Of course, this is a very short report.

Mr. DUKE: But at that time it struck you as an accurate report of what you said so far as it was material. Now let me read it: "Proprietary Medicines. In the course of an inquest held at Southwark yesterday"—that is how it ran, and then I suppose it was your clerk who wrote in the words "by Dr. Waldo."—No, those are my words.

You wrote them in?—Yes, I wrote those.

"In the course of an inquest held at Southwark yesterday," and then you wrote in "by Dr. Waldo," "on the body of Alfred Albert Cushing, aged 42, a labourer lately living in Queen's Buildings, Southwark, who died of consumption last Friday, the widow said her husband never cared to have a doctor as he thought doctors did no good. He doctored himself, she said, and any medicine he was told of he would buy He was taken ill on Dec. 22nd and never rallied. It was stated that the deceased used an inhaler which cost 3 guineas and the spray 8*s.* an ounce. The instrument was an American invention, and the deceased bought it from a gentleman in London. (The Coroner): It is a quack remedy. People reap fortunes from proprietary articles. Is that right?—(Dr. Paton, a witness): I do not think so.—(The Coroner): The Government do not guarantee proprietary medicines, but the people think they do. The sooner the Government do away with it the better. "They get thousands a year from the system.—(Dr. Paton): Most of these things are harmless.—(The Coroner): But it is a fraud." Is that what took place?—Yes; as far as it goes.

Mr. Justice RIDLEY: Was the fraud in the Government stamp?—I did not make use of the term "fraud" as applied to the stamp; it was applied clearly to the cure—Dr. Tucker's so-called cure for asthma and bronchitis and other affections.

Mr. DUKE: Did you keep copies of any other reports?—No; I have not.

Just look at this and see if you saw that in the newspaper (handing cutting to the witness).—I do not remember ever having seen this. I may have seen it, but of course it is a long time ago now; it is over a year.

But it is a report of that inquest, is it not?—Yes; apparently.

There the reporter evidently understood you as saying that the system of stamping these things with Government stamps was a fraud—Yes, I see what you mean; it says "The system is a fraud." That differs from the one which I sent to THE LANCET.

That puts upon the other the meaning which I suggest it actually bore.—Which is incorrect.

Let us see how that may be.—That is not correct.

We shall have to look at the document for ourselves. The one I first gave you was the one which you sent to THE LANCET as being a correct account of what had taken place?—Yes, it was.

When did you communicate with THE LANCET again about this matter?—THE LANCET wrote to me, so far as I can remember, asking me for papers that were handed up in court.

That was after this action was brought, was it not?—I cannot say that. I think it was before. I instructed my clerk to send them. My clerk would really know more about that than I; I did not myself send them.

When did you see THE LANCET people or their solicitors about this matter and give them some further information as to what you are alleged to have said at the inquest?—I believe that was subsequently to the action.

So I *suppose* it was.—I was asked by THE LANCET to give information, but I could not tell you the date.

I have the pleading before it was amended, which had been delivered on the 9th July and it was redelivered as amended on the 21st November. Was it some time between the 9th July and the 21st November of last year?—It might have been; I really could not remember.

them, but it is not to the credit of the dentist to publish these cases, and so many more of these cases exist than are published, so that the other dentists do not know the risk to the full extent.

Mr. Justice RIDLEY: I think we had better get back to the point.

Mr. DUKE: Had not you better recommend the dentists to THE LANCET, do not you think?

Re-examined by Mr. ELDON BANKES.—Even in modern practice the use of cocaine in dentistry is not followed to the extent it was?—I do not think so.

Mr. DUKE: That is a leading question.

Mr. ELDON BANKES: You have been asked about the natives of America chewing the coca plant?—Yes.

Is cocaine the concentrated extract of the coca plant?—It is the active principle, yes.

And of course it would be in a very different degree of strength from what it would be if the leaf was chewed?—It is.

HENRY ALEXANDER FRANCIS, *examined by* Mr. ELDON BANKES.—You carry on your profession at 2, Henrietta-street, Cavendish-square?—Yes.

Mr. Justice RIDLEY: What are you?—A Bachelor of Medicine and Surgery, Cambridge.

Mr. ELDON BANKES: I think you have full Cambridge qualifications and are a Member of the Royal College of Surgeons and a Licentiate of the Royal College of Physicians, London?—Yes.

I think for some considerable time you have devoted your attention largely to the treatment of asthmatic cases?—Yes, about 11 years.

And a very large number of people have consulted you with reference to asthma?—Yes.

And amongst those patients have you had a considerable number who have been using the Tucker treatment?—I have a large number.

Before I come to your actual experience with those patients I want to ask you generally about this specific. You know of what it consists, do you?—I have heard analyses and I have heard it in court here.

Have you heard of analyses of it before you came into court?—Roughly, yes. I have seen printed formulæ which are reputed to be the analyses; I never took much interest in them.

What do you think are the active constituents of this specific?—From what I have heard and what I have seen, I should say chiefly cocaine, atropine, and hyponitrous acid—the nitrite element in the form of sodium nitrite. I did not know it was sodium nitrite.

Mr. Justice RIDLEY: We do not want all these over again.

Mr. ELDON BANKES: I will ask you generally, Do you agree with what has been said by the medical witnesses you have heard with reference to the action of cocaine?—Yes.

So I need not go though it in detail. In your opinion is cocaine a dangerous drug to use except under very careful supervision?—Very.

Do you think that the use of this Tucker specific with the instructions that accompany it is likely to cause injury in certain cases?—I do.

What would be the nature and kind of injury you would expect to find having regard to these constituents of the specific?—I could deal better with the injury that I have found than the theoretical injury.

From your experience what do you find is the injury to patients from the use of this specific?

Mr. SMITH: I should like to refer to the pleadings on that. I do not know how far my learned friend proposes to go on this line of question. We are now coming to particular observations made. If we had had warning on the defence that any issue of that kind was going to be raised it would have been perfectly easy for us to have had hundreds of people here who have used it instead of a limited number. It is a new case altogether against me.

Mr. ELDON BANKES: It is evidence of our statement that these drugs are dangerous. I do not mind whether I give it as the result of the doctor's actual experience or whether I ask generally what his view is in regard to it.

Mr. Justice RIDLEY: Evidence of your statement that they are dangerous?

Mr. ELDON BANKES: Yes.

Mr. SMITH: That is in the amended defence, it was not in the original defence. The only statement relevant to that point is: "The constituents of the said specific are cocaine and atropine." That is the original defence, and added to that is "which poisons are dangerous if used without medical advice." In a plea of fair comment surely if the case to be set up by the defence was going to be that the use of this specific had in fact produced deleterious consequences to persons who made use of it, we ought to have been given some warning so that we might have dealt with that in our own case or made arrangements to deal with it. As my learned leader reminds me I do not recollect any cross-examination of the plaintiff adequate to suggest that that is the line to be adopted by the defendant.

Mr. ELDON BANKS: I suggested to him it was extremely injurious to the patient's heart and very improper to use it in cases of heart trouble.

Mr. DUKE: This is a very material matter. It is sought now, as I understand, to give evidence of some specific instance.

Mr. ELDON BANKS: No, not of specific instances at all.

Mr. DUKE: Well, even worse than that, to make a general statement that certain persons within or without the knowledge of the witness have been injured by the use of this specific. There is no possibility of effectively cross-examining to it, and there is no possibility of rebutting it. There is no knowledge as to who the persons are so that they could have been seen, or it could be ascertained whether they had used the specific or not, and we have not had the opportunity.

Mr. Justice RIDLEY: You do not call anyone who was injured by it.

Mr. ELDON BANKES: I do not call any one of this gentleman's patients.

Mr. Justice RIDLEY: Then I think I must say it is very objectionable evidence, but I think I must admit it.

Mr. DUKE: But how am I to deal with it?

Mr. Justice RIDLEY: I do not know indeed, but I think we must take it. I think it is a very objectionable form. I think particulars should have been given of this. You charge the man with fraud, but this is not the way to prove fraud.

Mr. DUKE: It is said that the plaintiff could be charged with fraud for certain things. Now it is proposed to give evidence that certain persons, with or without his knowledge, have or have not used the specific.

Mr. Justice RIDLEY: I think I must take the evidence, but I think it is very objectionable.

Mr. DUKE: I submit it is inadmissible. Here is a plain issue of fraud, and this is evidence which is not relevant to any of the questions raised.

Mr. Justice RIDLEY: I think I must receive it for what it is worth.

Mr. ELDON BANKES: I propose to put the question in a form in which I think my learned friend ought not to object.

I ask you as a medical man whether or not the use of this specific is likely to be dangerous?—Certainly.

I ask you to explain what, in your opinion, you mean by dangerous, and how it affects patients or is likely to affect patients?—The chief effect observed is on the heart. Certainly you would say that the patient when he has further attacks of asthma is much more likely to have heart complication and heart embarrassment than he would have had previous to his using Tucker. Another thing is when they have used it for a great many years so that they have had an accumulation of the remedy the nervous system generally becomes much affected and the muscular system also later on, but I think that the most important observation is the weakening effect on the heart.

Is that what you would expect to find from the frequent and repeated use of this liquid containing the constituent which we now know it to contain?—It is exactly.

Have you in your experience observed that that is the effect of it?

Mr. DUKE: You understand that you are asking these questions at your own risk.

Mr. ELDON BANKES: Certainly.

The WITNESS: That is quite a common experience.

Is asthma a very distressing complaint?—Very.

Is this specific one that is likely to relieve the attacks of asthma?—I have never seen anything that will relieve a mild attack of asthma so readily.

And to what do you attribute that?—I attribute it to the specific. Until recently I have not really thought whether it was atropine or the cocaine, or the nitrite of soda. I think it is all three, especially as the imitations do not seem asthma then in his case you would not describe it as a fraud?—I should describe it certainly in Tucker's case as a fraud most distinctly.

Never mind Tucker's case. I understand your view with regard to Tucker although I have not asked you. Do you know what the question was which I asked you?—I understood you to say if this were dispensed by a properly qualified medical man.

As a specific for asthma?—I should say it was distinctly wrong if he described it as a cure.

Would you say if it was given by a medical man as a specific for asthma that that was a fraud on his part?—I should say it was.

Why?—Because asthma is an incurable disease in my opinion.

But suppose he took the view that he was able to repel the attack whenever it threatened, would you still say——*That is another thing altogether.*

Would you say still that it was a fraud on his part?—No; *I would not if under his supervision and he did* not profess to cure the disease. Certainly that would not be a fraud in my opinion.

The whole substance of the matter with regard to a transaction of this kind, fraud or no fraud, is one of the honesty of the person who is acting, *is it not?—Yes.*

As to Tucker's honesty, I understand you to say that you formed the worst possible opinion?—I have certainly formed a bad opinion.

That is what I gathered, but I wanted it clear from you. Having formed the worst possible opinion of Mr. Tucker, what you told The Lancet has induced them to take the responsibility of expressing that worst possible opinion. That is so, is it not?—They could do what they liked. I sent them the cutting.

Is that not what has happened?—Yes.

Mr. Justice Ridley: Why did you send it to them at all?—Because I considered it a matter of scientific interest for The Lancet to do as they liked with, both for the medical readers and general readers.

You sent it to a newspaper so that they might publish something about it?—Yes; I think that medical students and medical men should know about these remedies and secret remedies because the patients very often consult medical men, and I think it is only right that they should be able to give proper answers to questions which may be put by the patients.

Mr. Duke: All I asked you was whether The Lancet had come up in your judgment to a complete expression of your view of the fraudulent conduct of Mr. Tucker?—I have read what they said in their article. They simply repeated what I said—that it was fraudulent—and agreed with me.

You have no doubt that the issue which The Lancet raised about it was whether Tucker was personally guilty of fraudulent conduct? You have no doubt about that?—I do not know what The Lancet thinks about it.

That is what you thought about it?—I thought it was fraudulent, certainly.

On Tucker's part. That is what you wanted them to think about it, was it not?—I did not express any——

Was it your intention that they should think that?—I simply left it with the Editor of The Lancet to do what he liked with.

Are you satisfied that they have taken the view which you say you took?—Of course the view I took that it was fraudulent and a quack remedy they certainly have taken, but I say nothing about the comment they made and the rest of it.

Tell me which is the part that you are not going to countenance.—I have read all of it; I have read it through.

Mr. Justice Ridley: Do you mean about the advertisements?—Yes.

The plaintiff has never advertised at all.—No, the plaintiff never advertised.

Mr. Duke: Just look at this and see which is the part which you think goes beyond what even you intended.

Mr. Eldon Bankes: He did not say that.

Mr. Duke (to the witness): Never mind Mr. Bankes; look at the document, please.—They mention my name as the Coroner: "rightly stigmatised this mode of dealing"—meaning the plaintiff's—"as a fraud." I quite agree with that.

I quite understand. Which is the part you do not agree with?—I do not say I do not agree with any part of it but I am not responsible for what The Lancet may have said.

But you do not draw any distinction.—Do you want me to say whether I consider that fair comment?

No, I do not want your opinion about fair comment.—Because I can say that.

Mr. Justice Ridley: The jury will have to say that if there is any case for them, but you say it was fraudulent because he said it was a cure.—Yes, but I could give my further reasons.

That is the reason you give us at present?

Mr. Eldon Bankes: No, he did not say that with submission.—My reason for saying it was this, that I consider that true or spasmodic asthma is an incurable disease and cannot be cured by drugs although I do most certainly agree that it may be alleviated and relieved; but with regard to bronchitis, bronchitis is merely, in my opinion, a symptom of many distinct diseases. It is a symptom of gout; it is a symptom of heart disease.

Mr. Duke: Could we stop there?—No one remedy can cure all these forms of bronchitis.

Mr. Justice Ridley: You are not asked all that, as you know very well.

Mr. Duke: There is only one other thing which I am going to ask you and that is this: have you ever tried to cure asthma or to relieve asthma with Tucker's specific?—No, I never have.

So that you have no personal experience in an asthma case of whether it will either relieve or cure?—Not with this *particular cure.*

Not with Tucker's cure?—No—or specific; it is the same thing.

Re-examined by Mr. Eldon Bankes.—You have been asked and you have stated that you are a medical coroner. Do you practise at all as a doctor?—No, I do not. I give *my whole time to my duties* as coroner.

Mr. Justice Ridley: He has medical knowledge.

Mr. Eldon Bankes: Yes; you have medical knowledge because you hold the high qualification of Doctor of Medicine at Cambridge University?—I do.

But you do not any more practise?—No, I do not at present. I have practised in the past.

You have no interest in The Lancet newspaper, I need hardly say?—I have no interest whatever.

You sent that newspaper account to The Lancet?—I did.

Two different newspaper accounts have been put in of this inquest and there is a third, all differing, but at the time you sent it did you notice particularly as to whether or not it used the word "fraud" correctly in the newspaper report—at the time you sent it?—I did.

I mean at the time you sent it.—Yes; I read it and looked through it carefully.

Does it correctly reproduce what you said with reference to the fraud—I mean the newspaper report?—It does.

Just look at it again.

Mr. Duke: He has said that it does. You cannot cross-examine him.

Mr. Eldon Bankes: I understood him to say it did not.

The Witness: It says, "But it is a fraud"; that refers as I read it to the treatment—Tucker's so-called cure for asthma and other complaints.

Mr. Justice Ridley: It does not necessarily follow; but I am sure we shall all take the witness's evidence as reliable. It would not necessarily follow from the report itself because it might be thought to have something to do with the price; it might be "thousands a year from the system," and also it might have regard to the stamp.

Mr. Eldon Bankes: You read the report as though it indicated that you had used the word "fraud" with reference to the system. You read the report in that way?—I read it as referring to the treatment.

And in that sense you say you think it was accurate?—Yes.

And therefore you sent it to The Lancet?—Yes.

You are now asked about what you said to The Lancet at subsequent dates. Did you see the solicitor with reference to your evidence in this action?—I did. He called upon me.

Did you then tell him what had actually happened?—Yes, I did.

Did you in substance report the evidence which you have given here to-day?—I did.

Sir Richard Douglas Powell, *examined by* Mr. Eldon Bankes.—I need hardly ask you about your qualifications; you are the very well-known physician?—I am.

Have you been asked to consider the matters arising in this case?—Yes, I have.

two or three times at the most instead of blowing themselves up with it, that they had better desist from using the remedy entirely.

I am asking you as to the two or three times, not blowing themselves up with it. Do you leave them upon each occasion of inhalation, that is of the two or three times a day, to inhale until the attack is relieved or until the paroxysm is relieved?—If they cannot get relief from two or three inhalations they must not go on and fill themselves up with it.

Do not you know that it is exceedingly difficult to many people to inhale at all, that ordinarily it is a difficult thing to inhale effectively?—Well, they require a little practice.

I come back now to the gentleman you spoke of.—I think I can tell you his previous address.

He seems to be a gentleman who received the treatment in July, 1900, and the balance of his supply of fluid in January, 1901; is that the gentleman?—Very probably.

Do you know his initials?—I rather fancy it is C., or C.E.

Do you know where he had been living before?—He had been in St. Andrews.

Then we may take it it is the same person?—It is the same man, I think.

We may take it from you that this is a gentleman whom you advised not to use the inhaler more than two or three times a day. When was that?

Mr. Justice RIDLEY: It was last week, was it not?—No; some three or four months ago.

Mr. DUKE: He told you that for five years he used the inhaler and derived undoubted benefit from it.

Mr. Justice RIDLEY: That is three or four months ago?—I believe so; I cannot remember exactly. It was three or four months ago I saw him first.

Mr. DUKE: He told you that for five years he had used the inhaler and derived undoubted benefit from it?—As far as I remember. What makes me fix the five years is because in the history of the man's case he told me that two years ago he had been very strongly urged by a doctor to desist from using this remedy, because the time would come when he would be sorry, and it would break him up.

What is his time of life?—I suppose he is 50, perhaps older—55.

What is he suffering from?—Asthma.

Anything else?—Practically nothing else.

Any trouble of the heart?—He has had very great heart symptoms.

For many years?—I could not tell you that without my book.

Has he suffered from heart symptoms all the time?—Certainly latterly, the last few years.

But I am asking you now?—I cannot tell you without seeing the man again.

How many times did you see him?—I suppose I have seen him roughly six to ten times so far.

When you came to advise him with regard to the specific knowing that he had heart symptoms you advised him to use it not more than two or three times a day?—May I explain?

Is that the fact?—Yes.

Yet you say this is a thing which he ought not to have used at all; is that so?—Not as you put it.

But you say it is a thing he ought not to have used at all?—He would be better without using it at all and I told the man several times he made a mistake to stop using it suddenly because he went into a very serious condition as a result of lacking the immediate stimulating effect of the use of it.

He was worse after he left off using it?—For the time being.

For how long?—Nearly ten days or a fortnight I suppose.

After that did you find some substitute for him?—I found a remedy.

What remedy did you give him?—I treated him in my own method of treating him.

Is that a method of burning the nose?—It has to do with burning the nose and general health and diet.

Having used the inhaler beneficially for years, and being put off it, and being the worse for it I suppose he had his nose burnt?—You put it in that way, but that is not quite correct.

That is accurate, is it not?—No.

He had used it in the early years with benefit?—He had used it in the early years with benefit, but when he came to me he was in a very serious condition indeed, I considered, from the use of the remedy and the return of the asthma which he had very seriously. The man has not any heart disease, but he *has* heart weakness which is the result partly of the asthma, and which has been aggravated, in my opinion, by the use of the Tucker.

Does not that depend entirely on whether the Tucker counteracted the effect of the asthma?—But it *did not*, that is the point. By the time he came to me it had little or no effect upon him. Yet he could not stop using it as I have found in several cases.

But you found that he did stop using it?—After I had urged him.

He had not had his nose burnt until he stopped using it?—Well, not until I burnt it.

You stopped him using the Tucker, and burnt his nose instead?—Yes.

Re examined by Mr. ELDON BANKES.—My friend wishes to make a joke of this case, but at the time the gentleman came to you was he in a serious state of health?—Yes, he was in a serious state of health.

Did you ascertain how frequently he was using the specific when he came to you?—Practically using it constantly.

What do you mean by constantly?—20, 30, or 40 times a day. I am speaking not of the exact number of times in that particular case, but I imagine from what he told me he used it from 20 to 30 times a day.

Is that a condition in which a patient might very likely get, in your opinion, if he was using this stuff without warning?—Yes.

You told him that he had better stop it and use it only two or three times a day; but you say he stopped it altogether?—Yes. I had intended he should use it two or three times a day; that was to break him of it. My intention was to stop it as I had with other patients.

When he dropped it, you say he got into a very serious condition indeed. What is that due to? I put it down chiefly to nervous exhaustion and heart trouble that he suffered from more than the asthma when he stopped the remedy. I put that down to the lack or want of the stimulating effect, the immediate stimulating effect of the drugs which he had been using.

Is that the condition of things you find in a patient suffering from any habit of this kind?—Exactly.

If you stop it immediately there is a temporary collapse?—This man went into a very similar corresponding condition to a chronic alcoholic case; if you stop his liquor altogether he is quite likely to go into a state of delirium tremens, and stopping this man's Tucker in that way had a similar effect.

AUGUSTUS JOSEPH PEPPER, *examined by* Mr. HUGH FRASER.—You reside at 13, Wimpole-street, Cavendish-square? I think you are a Master of Surgery, London, a Bachelor of Medicine, a Fellow of the Royal College of Surgeons, England, and surgeon to St. Mary's Hospital?—Yes.

I think you have had submitted to you the analysis of Tucker's specific prepared by Dr. Willcox?—Yes.

And you have seen the instructions and the pamphlet?—Yes.

You are familiar with the nature of these drugs, cocaine, atropine, and so on?—Yes.

What is the action of cocaine?—Locally an anæsthetic; internally a heart depressant.

Is it a drug that can be properly used even in small doses except under medical advice?—No.

Is it a drug which requires to be used with the greatest care even in small doses in the case of a person suffering from heart disease?—Certainly.

Or if a person is suffering from kidney disease?—Certainly.

Or from consumption?—Yes.

Is it not the case that if a person is suffering from any one of these diseases which I have mentioned he may have asthmatic symptoms?—Certainly; we speak of them as cardiac asthma and renal asthma.

And the ordinary layman who is ignorant of things medical might very well think he was merely suffering from asthma?—Certainly; I should say in nine cases out of ten where the ordinary public think they are suffering from asthma they have no true asthma at all; it is merely a symptom of another disease, a more general disease.

You are familiar with the analysis of this specific?—Yes.

I am not putting that as a reflection at all upon medical treatment, you understand?—Yes.

Mr. Justice RIDLEY: Pickmeyer did not go to Harrogate. One witness did. He was a wine merchant. One witness was ordered to Nauheim and another gentleman went to Mont d'Or. I think that was Lord Ashburnham.

Mr. DUKE: Yes, my lord; I was not in court when his evidence was given.

Mr. Justice RIDLEY: It was Lord Ashburnham who went to Mont d'Or.

Mr. DUKE: Undoubtedly; but Mont d'Or is a place where asthmatic people are sent, and Nauheim is another place.

But you do not remember Mr. Pickmeyer's case specifically?—I cannot.

In a great number of cases it is notorious that asthma quite resists medical treatment?—It is a very obstinate complaint, yes.

And I do not gather from your evidence that you at any rate would think it improper that a medical man should prescribe either cocaine or atropine or a fluid which should be compounded of those ingredients for the treatment of his own patients if he thought fit?—If he thought fit certainly he would have the right.

Mr. Justice RIDLEY: Do you know of a better specific than this for asthma?—There are a great many specifics, my lord.

Do you know a better one?—They all contain much the same thing.

As this one?—I do not think many of them contain cocaine, but they nearly all contain atropine or belladonna.

Is it within your knowledge that those other specifics having once been begun fail in their operation after they have been used for some time?—Patients get accustomed to them all and they have to use them more and more frequently and sooner or later they suffer from the use of the remedy. That is my experience.

It is the fact, as we have heard, and it is correct that they are similar, you say, but without cocaine?—They are all more or less secret remedies and I cannot answer for the composition of any of them. I only know from their effects upon people I have seen that they do contain similar remedies of the belladonna class. I cannot be sure about the cocaine. That is a much more subtle drug.

But "contain similar remedies" would be right, and they all begin to fail in their operation and have to be used in larger quantities?—They have to be used in increasing quantities because the patient acquires a habit of using them.

I understand that you cannot compare them with this one, that is, with this particular specific of Mr. Tucker as to their effectual or ineffectual use?—In some cases I have known one remedy to give more relief than another. They vary in that way.

Have you been in court during the whole of the hearing or have you come in this morning?—I have been in court for the last two hours.

But you were not here yesterday?—I was not here yesterday.

We had several gentlemen here yesterday, some of whom at any rate said that they had such freedom from attack now that, carrying the specific with them, they did not find the necessity to use it?—Yes.

That does not show a tendency to increasing user, does it?—I did not hear the evidence and I cannot say.

I am asking you to assume for the moment that I am giving it to you accurately. If you assume that the witnesses who have been here had suffered grievously from asthma and had come to such a condition since they used the specific that they had practically discontinued the use of it, although they kept it by them, that would not show a tendency to increasing user, would it?—You cannot take individual cases.

But we must take individual cases?—I am afraid you cannot.

Do you mean that we ought to have the whole of our 25,000 users here?—I am only speaking of those cases where relief has been given by using anti-spasmodic remedies, which are the most powerful remedies in our Pharmacopœia and are extensively used by medical men.

And have not acquired a tendency to increased use?—I have no evidence of that.

But it must enter into the consideration of the conclusion scientifically, must it not?—I am afraid my opinion was given on cases I have known to the contrary. You asked me for my opinion.

I am cross-examining on your opinion and you gave it to me?—Yes.

You told us you had this pamphlet. I wish you would take a copy. It is said that this is put about to suggest that this thing produced an absolute cure. Take page 17 of this pamphlet, where the testimonials begin. I am not going to take more than three or four of them, but I must call your attention to that. Have you got it?—I have.

Take paragraph 3 in the first: "Your specific, whether it cures or not, is simply marvellous in the prompt relief it affords;" take the next at the fourth line.—Yes.

"I cannot of course say I am cured of asthma; but for the past five months, in which I have used your instrument, I have had greater freedom from attacks, and, what is of great importance, a ready and effective means of relief which has never failed me." Now take the next page, the second line: "I have used the remedy for nearly nine months, and though I am not in any way cured, during that time I have been in no way bothered with asthma." I am not going through the whole of them. I have taken the first three testimonials. Are not those representations to the people to whom this book is addressed that there are people at any rate who will find themselves cured by the use of this remedy?—Yes; they are using the most powerful remedies in the Pharmacopœia, and I do not see why they should not be benefited by them.

Further examined by Mr. ELDON BANKES.—My learned friend's cross-examination has enabled me to ask questions which I could not have asked before, but which I am desirous to ask now. Yours is, I think, a consulting practice?—Yes.

Have you had a number of patients come to you who have been taking this Tucker's specific?—I have seen a good number altogether.

My lord has asked you a question about these asthma remedies generally and their effect and you have told him that patients get accustomed to them and have to take gradually more and more and finally get into the habit of taking them. From your personal experience is there any difference in the cases you have had before you between patients taking other kinds of remedies and patients taking Tucker's remedies in that regard?—No; I could not say there is any difference.

You have said in answer to my learned friend that you have felt it sometimes necessary to stop the use of Tucker's specific altogether and in other cases to say that it should be used with extreme caution?—Yes.

What cases have they been in which you have ordered it to be stopped?—In a certain number of these cases patients fly to the remedy with great facility. They use it too much and they get weak and irritable hearts in consequence. It affects them through the heart. That is my experience.

In your practice have you found cases of patients actually being injuriously affected by the too frequent use of this liquid?—I have in some cases to advise them to stop the remedy and in others to use it with very great caution.

And is that because of the actual injurious effects upon those particular patients which you have found this remedy has been causing?—It is like all other powerful remedies of the class. People are apt to take it too frequently and to get injured by the use of it. The remedy gives them relief; they fly to it on very slight appearances of the symptoms and they acquire a habit, such as the morphia or the opium habit. That is how I look at it.

And the acquisition of that habit is accompanied by injurious results to them, and you say chiefly to their hearts?—It spoils their hearts.

Have you found any of the cases in which you have ordered it to be stopped that they have stopped it?—Sometimes I have not seen the patient again. They consult me and go. They take my advice or leave it as they like.

You have said in answer to my learned friend that asthma tends to weaken the heart?—Yes.

What is the operation of the cocaine with reference to the heart?—It is a decided depressor of the heart.

If you use a remedy which tends to depress the heart if you are suffering from asthma which itself tends to weaken the heart is that a good thing for you?—Of course, the first effect of any remedy, and I take it the active agent in Tucker's remedy as I understand it (because I have only just learned the composition of it) is atropine and the first effect of this drug is to diminish the spasm, and inasmuch as it relieves the spasm it relieves the pressure on the heart, but as the patients go on using the drug over and over again without

And, unfortunately, the failure of the medical profession to relieve it is very common, is not it ?—I daresay.

Re-examined by Mr. ELDON BANKES.—You were asked a question which I could not ask. You were asked whether anybody could honestly speak of dealing with this system as a fraud ?—Yes.

Before giving your answer had you carefully read these instructions and considered the nature of the specific and its possible effect ?—Certainly.

Have you personally any feeling against Mr. Tucker at all ?—Not at all.

Did you only come to the conclusion which you expressed to Mr. Duke after considering those materials ?—I did.

Whether it is right or wrong you still honestly hold that view ?—I do, certainly.

In your opinion is the indiscriminate sale of this specific liable to cause real serious mischief and injury to the persons who buy it ?—Certainly, I think it is pernicious and vicious.

And fraudulent ?—And fraudulent.

ARTHUR ROBERTSON CUSHNY, *examined by* Mr. ELDON BANKES.—I think you are a Fellow of the Royal Society, an M.D. of Aberdeen, Professor of the University College, London, and late Professor of Materia Medica and Therapeutics of the University of Michigan ?—Yes.

I think you have made a special study of poisons, have you not ?—Yes.

I do not want to go through the whole thing, but I want to ask you generally, do you agree with the opinion that has been expressed by Sir Douglas Powell about cocaine ? Did you hear him give his evidence ?—I heard Sir Douglas give his evidence. I agree in the general features.

In your opinion is it a dangerous drug to sell without careful precaution ?—Certainly.

One point I want to ask you about, and that is this: With regard to absorption into the blood of a poison if it is administered in the form of a spray, is that a form in which the poison is rapidly absorbed ?—Yes, most rapidly of all forms.

If you administered cocaine in that form it would absorb more rapidly than if it was swallowed ?—Very much more so.

Would it absorb more rapidly than if it was injected ?—Yes.

So that really it is the most rapid form known of absorbing a poison ?—Yes, except the intravenous method which is hardly used in man.

Have you considered the question as to whether or not the continuous and frequent use of this specific is likely to cause injury to patients ?—I think it is likely to promote the cocaine habit.

Is that extremely injurious to the patient ?—Yes, extremely injurious.

Cross-examined by Mr. DUKE.—How do you explain it that numbers of your medical brethren use these very same drugs for the very same purpose ?—I think these drugs might be used, if watched, without particular objection.

A man who has got asthma does not want to go to a doctor every time he gets a recurrence of an attack or the symptoms of an attack, does he ?—No.

Then his doctor will give him some remedy which he can use, will not he ?—Yes.

He will give him either something he can inhale the fumes of upon burning or something he can inhale in a vapour or something of that kind ?—I should not advise any doctor to prescribe cocaine.

I am speaking of what your medical brethren do, not what you would advise them to do.

Mr. Justice RIDLEY: You would not advise anyone to prescribe it ?—I would not prescribe cocaine in this way.

Mr. DUKE: Do not you know that they do prescribe cocaine ?—They do, because the dangers of cocaine are not properly appreciated.

Really, it is a mistake on the part of the doctors who prescribe cocaine; is that it ?—I think it is a mistake in any doctor to prescribe cocaine to be used internally in this way.

You would not go so far as to say he was guilty of fraudulent representation by prescribing cocaine ?—I should not say he was guilty of any representation at all.

Mr. Justice RIDLEY: Do you practise yourself ?—No.

Mr. DUKE: I gathered he did not, because he was introduced as a professor.

You say it is injudicious to administer cocaine at all, in your judgment; but, on the other hand, not really fraudulent, you think ?—The administration is not fraudulent.

But it is said on Mr. Tucker's part to be fraudulent; it is said that for him to say this will cure or relieve asthma is fraudulent, but for a doctor to give it to his patient as a thing which will relieve asthma is not fraudulent. Where is the difference ?—I do not think the doctor makes any representation that it is going to cure.

He provides it as a thing which is good for an asthmatic patient, does not he ?—I think he might, but no doctor promises to cure.

There are some things which a doctor will promise to cure, are not there ?

Mr. Justice RIDLEY: I have been promised many a time.

Mr. ELDON BANKES: But your lordship's ailments are very trifling.

Mr. Justice RIDLEY: Surely the doctor sometimes says to you that you will soon be all right.

Mr. DUKE: If the doctor says to you "You will be all right in a day or two," that is promising a cure, is not it ?—Yes.

That is one of the things a doctor is privileged in doing without being charged with fraud.

Mr. Justice RIDLEY: It would depend on what the jury think of these instructions. I do not think they have said it. You must read it all together.

Mr. DUKE: It has been suggested that they do, and they will have to be read later. Have you any doubt at all that large numbers of medical men and large numbers of specialists in asthma at the present time are using and prescribing a specific of just the same character as that which Dr. Tucker of the United States discovered ?—I really could not say whether anyone is prescribing for asthma a substance containing all the constituents of the Tucker cure.

Not all the constituents, but as near as they can get it. Do not you know medical men are prescribing what they believe to be an effective substitute for Tucker ?—I am not aware of the fact.

Why do you suppose it is that Oppenheimers are offering to the prescribing doctor and to the dispensing chemist a composition which is said to be an effective substitute ?—I was not aware that Oppenheimer had done so until I came to the court.

But when you find it is so, is not it perfectly obvious that the thing is in large use in the medical profession ?—In use, I admit.

Do you think Oppenheimers would take the trouble to advertise a thing of this kind in their list of drugs and give their preparation of it and recommend it specially unless it is a thing which is called for to a great extent ?—Called for, I may admit, but not to any great extent, possibly.

But they say so upon the face of that document. Just let me read it to you: "Many inquiries from important medical men have reached us regarding a certain preparation for asthma recommended by an American doctor. We introduce our Neboline compound which is similar in every respect and which from the reception accorded to it seems to meet all requirements, practically a specific for asthma." Is not it obvious upon that that medical men are largely using or seeking to use Dr. Tucker's remedy ?—I really cannot answer the question at all.

Would you mind applying your mind to it ? Oppenheimer's are one of the largest firms of wholesale druggists, are not they ?—Yes.

Are the people whom they usually supply the doctor who dispenses his own medicines and the dispensing chemist ?—I suppose so.

Can you give any other explanation for that statement in their catalogue except the explanation I suggest to you, that medical men in large numbers are calling for this specific and that it is being found effective ?—I can admit that the advertisement seems to me to mean that something of the kind is being called for. As to the numbers of medical men I should reverse my statement.

Mr. Justice RIDLEY: I find here a number of compounds; there are 21, I think, and 7 have got cocaine in them out of the 21 in different quantities in Oppenheimer's list. I am not going into the particular quantities because it would be too long, but it seems to be generally used.—I am very glad I am not responsible for Oppenheimer's list.

Mr. DUKE: Do you think Oppenheimer's are putting up medicines which are not being called for by the medical profession ?—I scarcely suppose so.

I gather that would be so if it is the fact that the medical

There is no sort of suggestion in the pleadings about this question of the cure of asthma.

Mr. ELDON BANKES: Very well, if you object, Mr. Duke, we will not press it.

Cross-examined by Mr. DUKE.—I gather that you regard cocaine as very much on the same footing as alcohol?—I do in regard to action, not in regard to dose.

Of course, a man might want half a pint of stout, but he would not want half a pint of cocaine. I have not asked any other witness about this. Cocaine is the product of a plant called the coca plant, is it not?—Yes.

It has been known for generations that the native of some of the States of South America chew the coca plant because of the sustaining influence its products have upon the system?—Precisely as people here take a glass of whisky.

They chew the coca plant because of its sustaining influence upon the system?—Because it makes them insensible to fatigue.

It is quite a national habit among those people in South America, is not it?—Just as much as whisky is in Scotland.

Now you are bringing things to their proper proportion. Those natives in South America do not die of it?—And the natives of Scotland have a way of living, or many of them, in spite of the whisky.

Mr. Justice RIDLEY: Are you a Scotchman?—I am.

Mr. DUKE: They are a very tough, robust race, the Scotchmen, in spite of their whisky. Those tribes in South America who have discovered the virtues of the coca plant have the credit of being exceptionally tough, robust people?—I am not aware that they have.

As a matter of reading do not you know that attention was called to the coca plant by the discovery of the great strains and fatigues that the tribes could bear who used it?—I have not understood your question rightly; I did not hear it rightly; but the reason, I quite agree, for which they use the coca plant is because they could undergo fatigue without feeling it. But exactly in the same way a man will go on doing extraordinary exertions with alcohol in various forms, but that does not say that alcohol thereby is preventing fatigue; it prevents him from feeling it.

Do not let us try alcohol in this case. Some of us take it with our lunch and we do not want to be disheartened. Does it come to this, that alcohol may be abused and cocaine may be abused?—It does.

With regard to the cocaine, take 1/20,000th part of a grain diluted in a volume of vapour, which would fill the lungs; would you, as a scientific man, speak of that as a poison?—Yes, it is a poison.

You would, really! You would say that a man who received into his lungs, diluted with a volume of vapour which filled the lungs, 1/20,000th part of a grain of cocaine was undergoing poisoning?—It depends upon——

I wish you would tell me.—Well, I should say yes; and may I elaborate that by saying this: I do not care about the question of dose, because dose is not an amount. A dose is something that acts upon the individual, and the influence upon one individual will not be the same upon another. As an instance of how far an infinitesimal dose, a mere sniff, will act upon one, take nitrite. We know that in Tucker's cure there is nitrite of sodium. I shall take another nitrite, which is volatile. Take the nitrite of amyl; if anyone cares to test it by one sniff they would soon find that an infinitesimal dose will produce the most marked effect.

Mr. Justice RIDLEY: And undoubtedly, I suppose, if you could get a sniff of prussic acid you will die?—Well, I do not know.

There are some poisons which are fatal in whatever quantity you take them?—No, my lord; it is a question of dose in every one, even with hydrocyanic acid.

But with the smell?—If you get enough smell of hydrocyanic acid you may get enough into the lungs to kill a man.

Mr. Justice RIDLEY: Then all these poisons are a question of degree?

Mr. DUKE: I should have thought so. I want to bring it down to the question of degree. Anyhow, you have told us a man inhaling in a volume of vapour that fills his lungs 1/20,000th part of a grain of cocaine is undergoing poisoning. None of the 25,000 people who have used these things seem to have been poisoned by this. How would you explain that?—You can bring from this country not only 25,000 but, I should say, 5,000,000 of men who have been taking the poison alcohol all their lives and who have not undergone poisoning.

Very well, I will accept it, and now let us pass on. You have given me an instance of 1/20,000th part of a grain. What is the smallest dose of cocaine recognised in the faculties of medicine as producing any medicinal effect?—That I cannot tell you, for this reason, that there are no definite experiments to ascertain the maximum dose.

It is stated in Squire's Pharmacopœia.—The question of doses depends not merely on the amount taken but upon the way it is taken. The dose that is stated in the Pharmacopœia I think is about one-twentieth to one-half, but that is intended as a rule to be something taken by the mouth. Anything taken by the lungs acts much more quickly, but I believe that we should ascertain the truth much more simply by getting rid of the question of dose entirely, and if any gentleman of the jury wishes to ascertain what one single whiff of a nitrite is like, and I say again there are nitrites which are one of the constituents of this cure, let him just take the stopper out of this bottle and take one whiff; that will convince him there is a definite action to be got from an infinitesimal dose.

I will bring you back from your nitrites to the matter I was asking you about. You know that the smallest dose of cocaine that is mentioned in Squire's Pharmacopœia as being capable of producing any medicinal effect is one-twentieth of a grain taken directly into the stomach?—I beg your pardon, that is your minimum dose, but that is an entirely different thing.

Is not that minimum dose the smallest quantity that can be expected to produce any medicinal effect?—No.

Then why is it the minimum dose?—Because it is the minimum usual dose for the average of mankind, but there are exceptions in whom that minimum dose may produce very unexpected and unpleasant results.

In one million, according to your judgment, how many of those exceptional persons are there?—I have no statistics to go on, and such statistics do not exist; therefore I cannot answer the question.

In your experience how many persons do you know would be affected medicinally by one-twentieth part of a grain of cocaine?—I have not known one, because I do not prescribe cocaine internally.

Mr. Justice RIDLEY: But have you known instances?—No. If I am asked, Have I known an instance, I can tell you of one where a hypodermic injection of an ordinary quantity of some preparation of cocaine into the gum produced complete paralysis of the respiration lasting for 12 hours, so that artificial respiration had to be kept up.

Mr. DUKE: Surgical operations are prone to suffer from accidents of that kind, are not they?—One does not usually consider the extraction of a tooth as a surgical operation.

It so happened that there was something abnormal, and the result of a somewhat simple operation was paralysis of the jaw?—No, nothing of the sort. The injection of cocaine took place before the extraction of the tooth; it was put into the gum in order to render the gum anæsthetic and free from pain from the extraction. The tooth was not extracted, but the patient, a healthy man, was at once thrown into such a condition of collapse that he had to be laid on the floor and artificial respiration had to be kept up for 12 hours, he knowing all the time that if they ceased to keep up that artificial respiration he would die, yet he being perfectly unable to move hand or foot.

Have doctors gone on using cocaine for the operation of tooth-drawing?—They have.

Although the tooth can be drawn without any alleviative at all, and in the case of poor people in the country districts commonly is drawn in that way?—It is so.

Is not that a fair test of the real danger there is, even from such a matter as the injection of pure cocaine into the jaw?—I should say not.

Then will you reconcile the practice of the doctors in that plain manner with the terrifying evidence which is presented here of the possibilities of the use of cocaine?—The reason is simply this, as I have said before, that some men are particularly susceptible to the action of cocaine. You cannot tell beforehand what those men are, and the number of these exceptions is small. People will go on taking the risk rather than face the certainty of pain in the extraction of the tooth.

And do the doctors take the risk, although they know it exists?—Dentists take the risk for one reason.

Mr. Justice RIDLEY: Because it is small?—Yes; and, moreover, these cases are not made known.

Mr. DUKE: But the dentists know them?—They do not know all of them.

But they know of some of them?—They know of some of

And, unfortunately, the failure of the medical profession to relieve it is very common, is not it?—I daresay.

Re-examined by Mr. ELDON BANKES.—You were asked a question which I could not ask. You were asked whether anybody could honestly speak of dealing with this system as a fraud?—Yes.

Before giving your answer had you carefully read these instructions and considered the nature of the specific and its possible effect?—Certainly.

Have you personally any feeling against Mr. Tucker at all?—Not at all.

Did you only come to the conclusion which you expressed to Mr. Duke after considering those materials?—I did.

Whether it is right or wrong you still honestly hold that view?—I do, certainly.

In your opinion is the indiscriminate sale of this specific liable to cause real serious mischief and injury to the persons who buy it?—Certainly, I think it is pernicious and vicious.

And fraudulent?—And fraudulent.

ARTHUR ROBERTSON CUSHNY, *examined by* Mr. ELDON BANKES.—I think you are a Fellow of the Royal Society, an M.D. of Aberdeen, Professor of the University College, London, and late Professor of Materia Medica and Therapeutics of the University of Michigan?—Yes.

I think you have made a special study of poisons, have you not?—Yes.

I do not want to go through the whole thing, but I want to ask you generally, do you agree with the opinion that has been expressed by Sir Douglas Powell about cocaine? Did you hear him give his evidence?—I heard Sir Douglas give his evidence. I agree in the general features.

In your opinion is it a dangerous drug to sell without careful precaution?—Certainly.

One point I want to ask you about, and that is this: With regard to absorption into the blood of a poison if it is administered in the form of a spray, is that a form in which the poison is rapidly absorbed?—Yes, most rapidly of all forms.

If you administered cocaine in that form it would absorb more rapidly than if it was swallowed?—Very much more so.

Would it absorb more rapidly than if it was injected?—Yes.

So that really it is the most rapid form known of absorbing a poison?—Yes, except the intravenous method which is hardly used in man.

Have you considered the question as to whether or not the continuous and frequent use of this specific is likely to cause injury to patients?—I think it is likely to promote the cocaine habit.

Is that extremely injurious to the patient?—Yes, extremely injurious.

Cross-examined by Mr. DUKE.—How do you explain it that numbers of your medical brethren use these very same drugs for the very same purpose?—I think these drugs might be used, if watched, without particular objection.

A man who has got asthma does not want to go to a doctor every time he gets a recurrence of an attack or the symptoms of an attack, does he?—No.

Then his doctor will give him some remedy which he can use, will not he?—Yes.

He will give him either something he can inhale the fumes of upon burning or something he can inhale in a vapour or something of that kind?—I should not advise any doctor to prescribe cocaine.

I am speaking of what your medical brethren do, not what you would advise them to do.

Mr. Justice RIDLEY: You would not advise anyone to prescribe it?—I would not prescribe cocaine in this way.

Mr. DUKE: Do not you know that they do prescribe cocaine?—They do, because the dangers of cocaine are not properly appreciated.

Really, it is a mistake on the part of the doctors who prescribe cocaine; is that it?—I think it is a mistake in any doctor to prescribe cocaine to be used internally in this way.

You would not go so far as to say he was guilty of fraudulent representation by prescribing cocaine?—I should not say he was guilty of any representation at all.

Mr. Justice RIDLEY: Do you practise yourself?—No.

Mr. DUKE: I gathered he did not, because he was introduced as a professor.

You say it is injudicious to administer cocaine at all, in your judgment; but, on the other hand, not really fraudulent, you think?—The administration is not fraudulent.

But it is said on Mr. Tucker's part to be fraudulent; it is said that for him to say this will cure or relieve asthma is fraudulent, but for a doctor to give it to his patient as a thing which will relieve asthma is not fraudulent. Where is the difference?—I do not think the doctor makes any representation that it is going to cure.

He provides it as a thing which is good for an asthmatic patient, does not he?—I think he might, but no doctor promises to cure.

There are some things which a doctor will promise to cure, are not there?

Mr. Justice RIDLEY: I have been promised many a time.

Mr. ELDON BANKES: But your lordship's ailments are very trifling.

Mr. Justice RIDLEY: Surely the doctor sometimes says to you that you will soon be all right.

Mr. DUKE: If the doctor says to you "You will be all right in a day or two," that is promising a cure, is not it?—Yes.

That is one of the things a doctor is privileged in doing without being charged with fraud.

Mr. Justice RIDLEY: It would depend on what the jury think of these instructions. I do not think they have said it. You must read it all together.

Mr. DUKE: It has been suggested that they do, and they will have to be read later. Have you any doubt at all that large numbers of medical men and large numbers of specialists in asthma at the present time are using and prescribing a specific of just the same character as that which Dr. Tucker of the United States discovered?—I really could not say whether anyone is prescribing for asthma a substance containing all the constituents of the Tucker cure.

Not all the constituents, but as near as they can get it. Do not you know medical men are prescribing what they believe to be an effective substitute for Tucker?—I am not aware of the fact.

Why do you suppose it is that Oppenheimers are offering to the prescribing doctor and to the dispensing chemist a composition which is said to be an effective substitute?—I was not aware that Oppenheimer had done so until I came to the court.

But when you find it is so, is not it perfectly obvious that the thing is in large use in the medical profession?—In use, I admit.

Do you think Oppenheimers would take the trouble to advertise a thing of this kind in their list of drugs and give their preparation of it and recommend it specially unless it is a thing which is called for to a great extent?—Called for, I may admit, but not to any great extent, possibly.

But they say so upon the face of that document. As to the numbers of medical men I should reverse my statement.

Mr. Justice RIDLEY: I find here a number of compounds; there are 21, I think, and 7 have got cocaine in them out of the 21 in different quantities in Oppenheimer's list. I am not going into the particular quantities because it would be too long, but it seems to be generally used.—I am very glad I am not responsible for Oppenheimer's list.

Mr. DUKE: Do you think Oppenheimer's are putting up medicines which are not being called for by the medical profession?—I scarcely suppose so.

I gather that would be so if it is the fact that the medical to do it when they leave out the cocaine, or one of the others—they do not seem to be so effective. It is the cocaine of the three I should say.

Mr. Justice RIDLEY: Is that a new idea to apply the three drugs?—The action of each of the drugs is very similar on the circulation.

Mr. Justice RIDLEY: I wish you would answer the question.

Mr. ELDON BANKES: My lord asked if it was a new combination of those three drugs.

Mr. Justice RIDLEY: Have you ever known anybody to do it before?—Not to my knowledge, but there are certain remedies which are supposed to be exactly the same.

I did not ask any such question. I wanted to know, as you know well, if this was a new invention or prescription. You did not know it before, is the answer; then it was new.—I am sorry I do not gather your question even now.

Mr. ELDON BANKES: Given the fact that it produces immediate relief in this way, in your opinion is a patient very likely to make frequent use of this inhaler?—Yes.

Is it a very frequent use of the inhaler which leads to the result which you have spoken of to the jury?—In my opinion it is the frequent use.

Mr. Justice RIDLEY: We have had all that before. We know about the action of cocaine.

Mr. ELDON BANKES: I believe for some time you have realised the danger of using cocaine in connexion with asthma?

Mr. DUKE: Does it matter whether he has or not? It is quite immaterial to the issue in this action whether this gentleman has realised it or not.

Mr. ELDON BANKES: I was going to ask another question upon that.

Mr. Justice RIDLEY: The question here is fraud and nothing else, as I have said over and over again.

Cross-examined by Mr. DUKE.—You have said that certain symptoms were what you would expect to find from the frequent use of Tucker's specific and that it is common experience that those symptoms follow its use?—Yes.

Will you write down the name of the *person in whose* case you say to your knowledge that last happened?—Will you tell me the symptoms again?

I want the name and address of the person in whose case you say this consequence you have been speaking of last happened?

Mr. ELDON BANKES: Of course, it is not for publication?

Mr. DUKE: Of course not.

The WITNESS: I should have to refer to my notebook for the address. I can give you his name.

Mr. ELDON BANKES: Do you want the address?

Mr. DUKE: I probably shall, because I am going to see whether there was any such person.

The WITNESS: I believe the number is 29. I can tell you by referring to my case-book.

I am not suggesting that there will not be any person of the name you mention, but I am going to inquire about it. (The Witness wrote the name and handed same to counsel.) Will you also give the date? It is the last person you saw about this matter. Tell me when you saw him first as nearly as you can, and when you saw him last. It is the last patient in whom it is said these distressing symptoms had arisen.—I shall require my notebook to tell you when I saw him first and when I saw him last.

Tell me about—The one I am thinking of was on Friday in the week before last.

You have the name here?—Yes; that is speaking from memory as to the date I saw him last.

When do you suggest that the gentleman you have named here had used this specific?—He used it up to the time he came to see me first.

How long was that?—He had been using it for five years, speaking from memory. If you had given me notice I could have brought my notebook here. As far as I know he had been using it for seven years and for five years it had no ill-effects. In the last two years he was getting worse and he came to see me. I told him I understood he was using it too frequently and I advised him very strongly to reduce the number of times at which he used it, because I believe if you use it not more than twice in the 24 hours it will do you no harm. He took my advice more strictly than I meant and has stopped it altogether; I believe from that moment he has not used it.

You mean he has ceased it altogether?—I believe he has ceased to use it. I told him it was injurious to use it too much and I think he has stopped it.

He was a man who had used *this specific for five or seven* years without becoming in any way dependent on it?—In his particular case not at the last.

Do you mean there was some great effort required?—Yes, very great effort.

Did the great effort arise from the fact that he had recurrent paroxysms of asthma?—No, I do not think so; it was necessary for him to stop using Tucker.

Does he still suffer from asthma?—He still suffers from asthma.

How long has he been a sufferer from asthma?—I do no know. I can tell you if I have my notebook.

Where is your notebook?—It is at my rooms.

You have not got it here?—No.

You knew you were coming here to make this attack?

Mr. ELDON BANKES: Is that a fair thing to put to medical man?

Mr. DUKE: Certainly it is an attack. You regard it as an attack, do not you?—I regard it as a *danger* to certain patients.

Mr. ELDON BANKES: The question is, Do you consider your evidence an attack?

Mr. Justice RIDLEY: It is an attack made upon Mr. Tucker; he is charged with fraud.

Mr. ELDON BANKES: If a witness comes and gives evidence on subpœna surely *it* is not fair to say it is an attack.

Mr. DUKE: I take it you have given the defendants' solicitors a proof of your evidence?—Not with regard to this particular case.

But you have given them a proof of everything you thought material?—Yes.

You did not think it material to give them a proof of this matter you have mentioned?—I think you will find I said that in certain *cases* it had had a distinctly harmful effect.

Did you know you were coming here to help to support a charge of fraud against Mr. Tucker?—I knew what was said in the libel.

I wish you would tell me. You did know you were *coming here to help* to support a charge of fraud against Mr. Tucker?—If it is a charge of fraud. I came here to give evidence from my experience of Tucker on behalf of THE LANCET.

Did you regard it as a charge of fraud?—I did not think of it one way or the other.

Did you know that the action was brought by Mr. Tucker because he had been charged by THE LANCET with fraud?—I was not aware of that till I arrived here.

But you know it now?—Yes.

And you are here to give evidence in support of the people who made the charge?—To say that a remedy such as Tucker is harmless when, as I consider, with the exception of one or two drugs, it is the most dangerous remedy you can obtain, I should say it was a deception.

Were you here to hear the evidence of numerous people who said it was not only harmless but *most* beneficial?—I did not hear it, but I can quite believe it; I think numbers would say it is most beneficial.

Have you administered it yourself or not?—What do you mean by "administered"?

Recommended it.—In a very great many cases I have told patients that they can use it—not those who have never used it before, because I think it is one of the most dangerous remedies, to begin with, you can find, but those who are using it I do tell them they can use it, as far as I can see with absolute safety, so long as they do not use it more than twice, or at most more than three *times* in 24 hours. I have told case after case the same thing.

Then patients of yours with your approval are using this deadly preparation two or three *times* in the course of 24 hours?—Yes.

Mr. Justice RIDLEY: How many sniffs each *time*?—I always tell them, instead of following the directions to take as much as they can get into their chest each time, that they must be content with as little as they can do with, and with one or at the most two sprays will have as much effect as a great many, and patients tell me they find it is practically what I say.

Mr. DUKE: They are to use it so as to procure the immediate relief from asthma, and that is what you tell them to do? If it can be done in two or three inhalations to leave it at that, but if it required more——?—To leave it altogether.

That is not what you said?—I *tell them* if they cannot be content with two or three applications in 24 hours, using it

Mr. ELDON BANKES (*to Mr. Rogers*): What are the prices of your atomisers?

Mr. ROGERS: The black one is 4*s.* 6*d.*

Mr. ELDON BANKES: And the white one?

Mr. ROGERS: 5*s* 6*d.*

Mr. Justice RIDLEY: And Oppenheimer's 6*s.* 6*d.*

Cross-examined by Mr. DUKE.—Do you know that while this action has been preparing for trial the solicitors for the plaintiff have written to your solicitors asking them to give them particulars of any instrument which they said compared with the plaintiff's atomiser? They wrote on Oct. 9th, 1907. Did you know that?—I did not quite follow that question.

Did you know that in the course of preparing for this trial the plaintiff's solicitors had written to your employers' solicitors asking them to give them the names of any atomisers which they relied on as justifying their statement that an equally good atomiser with Tucker's could be obtained very cheaply?—I knew they asked whether they could produce an equally suitable one, I think it was.

That is what was said and that is one of the questions, so they wrote and said, "We know of this one," naming it.

Mr. ELDON BANKES: It was a 1*s.* 8*d.* one.

Mr. DUKE: I quite follow.

Mr. ELDON BANKES: I think you ought to read the letter.

Mr. DUKE: I will read it: "Tucker *v.* Wakley. It is stated in paragraph 5b of the defence that constituents sufficient to make up one ounce of the specific together with a suitable spraying instrument could be obtained from any chemist at a cost of from 8*s.* to 9*s.* We have purchased from Taylor's Drug Stores, Holborn, at the price of 1*s.* 8*d.* a spraying instrument described as the Excelsior atomiser No. 11 continuous spray. Will you please inform us whether this is a suitable spraying instrument within the meaning of paragraph 5b. If it is, will you be good enough to give us the address of a chemist from whom such an instrument can be obtained and mention the trade name of the same and the price at which it is sold." That was a perfectly reasonable inquiry, was it not?—I should think so.

Mr. ELDON BANKES: May I interpose? You took out a summons for that.

Mr. DUKE: I am quite aware that we did not get it, but I am dealing with the reasonableness and fairness of it.

Mr. ELDON BANKES: But if the Master refused it on your own summons how can you say it was reasonable?

Mr. DUKE: I am quite aware the Master refused it.

You were going to make tests of this and were going to give evidence on it?—Yes.

Do you not think that you were going to give evidence as to the instrument which you relied upon and which you were going to test ——

Mr. Justice RIDLEY: Do you think this of much consequence?

Mr. DUKE: I do not think any part of the evidence which is now given is material, but it is given.

Mr. Justice RIDLEY: It is a very small incident in the case. I do not deny its materiality, but I do not know how far you think it worth following.

Mr. DUKE: Any observation from your lordship will prevent me pressing small points.

It would be more satisfactory, would it not, when you are making experiments to have somebody from the other side to check them—more satisfactory from a scientific point of view, I mean?

Mr Justice RIDLEY: I should like to know how he measured the grains of spray.

Mr. DUKE: I was going to ask him, but there was nobody there to test it. It would be more satisfactory that there should be somebody there.

Mr. Justice RIDLEY (to the witness): How do you measure a grain of spray?—May I explain?

Yes.—I place the apparatus containing the fluid on the pan of a chemical balance which weighs infinitesimally small quantities. After taking careful measurements of the weight and entering that I take the apparatus from the pan and then perform 100 compressions and put the apparatus back and re-weigh it. The difference gives the loss in vapour.

Mr. DUKE: Of course the extent of the identity of the two operations depends entirely upon the pressure of the hand of the person who is making the experiment?—Yes; it was always in the same hand.

I quite agree; but the mind behind the hand has a great deal to do with the pressure of the hand, has it not?

Mr. ELDON BANKES: What does my friend suggest?

Mr. DUKE: This is cross-examination. You choose not to give us an opportunity of seeing that these things were done accurately.

Do you know the gentleman who wrote this article?—I do not know the writer of the article, no.

Are you able to say whether he had any knowledge at all of either Tucker's atomiser or Tucker's specific when he wrote it?—No.

At the time when that gentleman wrote this article, which was in March last year, had you any knowledge of Tucker's atomiser?—Yes.

Had you made any experiments with it?—No.

Had you any knowledge of Tucker's specific?—Yes.

Had you analysed it?—No.

Re-examined by Mr. ELDON BANKES.—You are asked what knowledge you had of this specific.

Mr. DUKE: No, he was not.

Mr. ELDON BANKES: I should have thought he was.

Mr. DUKE: I only asked him if he had any knowledge.

Mr. ELDON BANKES: Very well, I will not pursue it.

My lord, I wanted to call some evidence about the Poisons Act, but I do not know whether my friend will agree. I had better call the witness, perhaps.

Mr. DUKE: I object first of all that it is irrelevant upon this trial.

Mr. Justice RIDLEY: I cannot say until I know what it is.

Mr. DUKE: My learned friend wants to call evidence as to the Poisons Act, and I take it it is as to the matters which he opened, or suggested in the course of his cross-examination with regard to the present condition of the schedule and with regard to an Order in Council. I submit that is irrelevant.

Mr. ELDON BANKES: It is to prove that the schedule to the Act has been extended so as to include these two drugs.

Mr. DUKE: I submit that that is irrelevant.

Mr. Justice RIDLEY: I dare say it is, but I do not know why you should object to it, relevant or not.

Mr. DUKE: If your lordship decides to admit evidence of it ——

Mr. Justice RIDLEY: I think I cannot exclude it.

Mr. DUKE: Then I will not take up time by requiring evidence to be given; I will admit it.

Mr. Justice RIDLEY: That is a fact one way or the other. If it has been done it has been done. I have reason to think that they have been exercising pressure lately to extend the operations of the Poisons Act.

Mr. DUKE: There is no doubt there is an Order in Council which puts cocaine into one of the schedules of the Poisons Act; I do not know which it is.

Mr. ELDON BANKES: There are two Orders which I rely upon. This is an Order in Council of Dec. 21st, 1869, and that recites a resolution of the Pharmaceutical Society of Dec. 1st, 1869: "Resolved and declared that each of the following articles"; and then it gives a number until we come to "Preparations of atropine" ——

Mr. Justice RIDLEY: Being in the posions schedule.

Mr. ELDON BANKES: "Ought to be deemed a poison in the first part of Schedule A of the Pharmacy Act, 1868." Your lordship will see the difference in a moment between Part I. and Part II. Then the next Order is of Jan. 11th, 1905, and that recites a resolution of the Pharmaceutical Society, and that enumerates certain articles, including cocaine and its salts and preparations of cocaine which ought to be deemed a poison within the meaning of the Pharmacy Act: "And also that each of the following articles—namely, cocaine and its salts—ought to be deemed a poison in the first part"; so that cocaine and its salts are under the first part of the schedule and preparations of cocaine under the second part of the schedule.

Mr. Justice RIDLEY: It is not yet four o'clock. I think we had better finish the evidence.

Mr. ELDON BANKES: I have one or two other eminent medical men——

Mr. Justice RIDLEY: I had hoped that you might conclude the evidence to-day.

Mr. ELDON BANKES: I shall, I hope. The only point which was in my mind was this: I have some other eminent medical men, but the question is whether I ought, after the number I have called, to pile up the number, because, of course, their evidence only comes to the same effect.

Mr. Justice RIDLEY: I shall make the same observation

In your opinion, would the use of it be likely to be dangerous?—Certainly, if used indiscriminately.

Mr. Justice RIDLEY: That is what he has already said.

Mr. FRASER: I have not asked him the question with regard to the specific.

Mr. Justice RIDLEY: It could not be used without proper medical advice.

Mr. FRASER: That is in regard to cocaine. I did not ask with regard to this specific. Will you just state shortly the reasons why, if it was sold to the public indiscriminately, it would be likely to be dangerous?—In the first place they would be inhaling it in many cases where they think they have true asthma and where the asthma is only a symptom of a far more dangerous condition. Very often it is a symptom dependent on organic heart disease or of advanced kidney disease.

In those cases what would be the effect?—The effect would be much more pronounced upon the general constitutional condition of the patient than if it was purely a case of asthma.

Would the *effects* be injurious or not?—Much more injurious.

Cross-examined by Mr. DUKE.—I suppose you have not administered, or caused to be administered, this specific to any of your patients?—No.

You know that a large number of specialists do give this specific to their patients for asthma?—No, I do not.

Is not it well known to be the most effective remedial agent for asthma there is?—Not to my knowledge.

Do not you know that?—No.

What do you suppose led Oppenheimers to introduce an imitation of this specific and to describe it as a specific for asthma if the thing was not being called for by the medical profession?—I do not say it has not been called for; probably it has, but you are asking my experience and knowledge and I tell you I have not any.

Have you any doubt at all that it has been largely called for by the medical profession?—I have not sufficient experience to form an opinion upon it. I have no doubt it has been very largely used.

I am not asking about largely used. I am asking about its extensive user by the medical profession. You have no doubt it has been?—I have said just the contrary; I have not sufficient knowledge to form an opinion.

Do you know one way or the other?—No.

Do you know you come here to help to support a charge of fraud against Mr. Tucker?—I know I come here to speak the truth and to give my opinion of the action of these drugs.

I did not ask you that.—I do not think it is a question for me to answer in regard to the fraud.

Did you know that the charge against which Mr. Tucker came to defend himself was a charge of fraud?—Certainly.

Did you come here to help to maintain that charge of fraud?—Yes, in the belief that it was a charge of fraud and that it was a fraud.

That is what I asked for and that is a candid answer. Will you tell me whether you would charge a man with fraud who believed this to be the best remedial agent there is and who sold it in that belief?—In the conditions in which it is sold, certainly.

Whether he believed it or not?—Certainly.

However innocent he might be of any intention to mislead, you would think it was proper to charge him with fraud?—I could not acquit him of intention at all.

Although the regulations are written by a member of your own profession?—The description of the action of the drug I should say: I am not speaking of the regulations so much.

And the description of the action of the drug is written by a member of your own profession.

Mr. Justice RIDLEY: It seems to me it is perfectly right as to the description of the action of the drug. Why do you say it is wrong?—I say it is a distinct falsehood.

It has been proved to be the truth. Do you mean the healing of the mucous surface?—Certainly.

But it does.—It does not.

Well, I do not know about that.—As a matter of fact it is just the opposite. Cocaine applied locally diminishes the healing process, and very frequently surgically I have not used cocaine because it frequently delays the healing process.

I am not speaking of cocaine; I am speaking of this specific. It certainly removes and causes the attacks to cease. I suppose that is because the mucous surface is benefited?—The word is "healing" the mucous surfaces. There is no interpretation applicable to that other than that the mucous surface is broken; so it cannot be healed.

No; not at all.—It is so, my lord.

Mr. DUKE: Take the case of a patient suffering from a violent paroxysm of asthma. Does that affect the mucous surface?—It causes it to be congested.

Mr. Justice RIDLEY: One witness said that before. I must say it never would occur to me that it meant a cut or a break in the surface in that sense.

Mr. DUKE: Everybody knows what is suggested.

Mr. Justice RIDLEY: You can speak of healing a disease.

The WITNESS: It is not a question of healing a disease. Stated here, it is healing a surface.

Mr. Justice RIDLEY: I will not argue about it with you; it is for the jury to deal with.

Mr. DUKE: Does asthma affect the mucous surfaces?

Mr. Justice RIDLEY: Because he uses the word "healing," which you do not think applicable, it is a fraud; is that it?—The learned counsel put the question to me on the question of healing; I say it is not true.

Mr. DUKE: Fraudulent mis-statement; that is your view about it?—If it is written by a medical man, as you tell me, he must know that the mucous surface is not broken.

Mr. Justice RIDLEY: You recognise no value in what I am putting to you, that the word "heal" may be used without a wound?—Not in connexion with those words; it is healing a surface.

Suppose there is an inflammatory condition of the surface cannot you speak of healing that? Surely you can?—That is not the sense in which it is understood by a medical man; I cannot say any more.

You do not seem to understand, or you will not.—Pardon me, I do.

Be careful, Mr. Pepper.—I am perfectly careful.

Mr. DUKE: Take the case of a man suffering from a violent paroxysm of asthma, does that affect the mucous surface, the mucous membrane?—It causes congestion.

Is that an unwholesome condition?—Yes.

Does the relief of the attack of asthma remove that unwholesome condition?—Yes, by removing the spasm.

Is not that a healing of that unwholesome condition?—But it is unlikely——

I wish you would answer the question?—Yes.

It is a healing of that unwholesome condition?—For so long as it lasts. The action of the drug is to diminish the spasms and the atropine causes a contraction of the blood vessels, but there is an inevitable relaxation afterwards, and therefore it is only a temporary relief of the congestion.

Do you mean that when the asthma has been relieved by the specific as soon as the effect of the specific has passed away the asthma recurs?—No, I do not.

I did not suppose you did. Do not you know that the attack of asthma may be relieved by the *specific* and pass away completely, and that there may be no recurrence of it for months?—It is quite possible.

Then why do you say that there is only a temporary healing of that unwholesome condition?—Because it is the fact.

Mr. Justice RIDLEY: But temporary or not, it is a healing.

Mr. DUKE: It *is* a *temporary* condition, is not it?—The congestion is a temporary one due to the spasm.

I quite follow. It is not a condition in which there is an abrasion or a laceration?—No.

It is a congested condition which needs to be removed?—Yes.

And everybody who knows anything about asthma knows that that is so, does not he?—I cannot vouch for anyone.

But do not you think that any intelligent person who had suffered from asthma or who had seen a victim of asthma in a paroxysm would know quite well that there was some internal cause which was spasmodic in its action?—Certainly.

And which was not a case either of laceration or abrading the surface of the organs?—Are you speaking of the opinion of a medical man?

I am speaking of any intelligent person who knew anything about the matter?—Yes; if he knew anything about the matter.

Do not you think there are people in the world besides medical men who may have a *little* common knowledge about asthma?—Very common, I should think it would be.

And, *unfortunately*, asthma is very common?—Yes.

your duty, as I submit, is to come to a decision to-day, as I am sure you will quite fairly and quite impartially, upon the evidence as it has been laid before you in the course of this trial.

First of all, let me deal with the libel, and if you have your copies before you I should like to read it through with you to see exactly what it is that is said, how much of it is applicable to the plaintiff, and what it is that it says about the plaintiff. You see it comes under a part of the paper which is called "Notes, Short Comments, and Answers to Correspondents." I do not mind whether you call this a note or short comment, but I should think the best way would be to speak of it as a note or an article. You will see that it has a heading and it is headed "Quack Advertisements"; and of course the object of the heading always is to indicate to the reader what the article or note is about. I shall submit to you when I have read it that the primary object of this writer in writing this note or comment was to deal with quack advertisements, and in dealing with these quack advertisements he did introduce incidentally this story with reference to Cushing and Dr. Tucker's specific. Now let me read it. It begins: "Quack advertisements. In the course of an inquest held at the beginning of the year it was stated that a labourer who had died from consumption had been using Dr. Tucker's asthma specific inhaler, for which he had given, according to a newspaper report which has reached us, three guineas, while the material with which he had sprayed himself had cost him 8*s*. an ounce." Now may I pause there. That is a statement as to something which had occurred at an inquest, and now you know that this is truly stated and that is a correct statement as to what had occurred at that inquest. Then the writer goes on: "Dr. F. J. Waldo, the coroner, rightly stigmatised this kind of dealing as a fraud." There again the writer is stating something which happened at the inquest, and he is also stating that he considers that what the coroner said was right. We know now that the coroner did say it and the question which you have to consider is whether the writer of this article was justified in his opinion in saying that the view which Dr. Waldo expressed was a correct view. He goes on: "and it is a humiliating thing for journalists to remember that such frauds could not be committed with any profit to the quack save with the coöperation of the press." Now he is travelling off into the question of quack advertisements generally, which does not, as I shall submit to you, refer to the plaintiff. "A correspondent has recently sent us a collection of advertisements of so-called proprietary medicines which he had cut from papers of high reputation in the country." It is now admitted, and you know, that those advertisements are advertisements referring to other remedies and do not include an advertisement of Dr. Tucker's specific. Then he goes on "inviting our opinion of them"—that is, of those advertisements. "Our opinion is that the misery wrought by quacks must be unknown to a good many proprietors of newspapers or they would hardly share with the quacks the plunder extracted from the public, mainly from the sick poor. The remedy is in the hands of the public who have only to signify their displeasure at reading in their journals invitations to be robbed and poisoned to find those invitations immediately cease. But the public are largely uninstructed and credulous and, alas, those responsible for the conduct of many of our journals take no trouble to enlighten them. They prefer to regard all protest against quack advertisement as emanating from the narrowness of the medical profession; this is certainly a convenient faith, but how it can be truly held by educated people passes our comprehension." That is the whole of it. The words of this article, taking it as a whole, which are objectionable, or which can be said to contain a libellous meaning, I think, are four. There is the first word "quack," there is secondly the word "fraud," there is thirdly the word "rob," there is fourthly the word "poison." Now there is no doubt whatever that as used in this article the word fraud does refer to the plaintiff in this sense that it refers to his course of trading. I shall ask you to consider whether the word "quack" or the words "rob" and "poison" refer to him. I will ask you in that connexion to bear in mind a letter which the solicitor for the plaintiff wrote when he complained of this article. You will find there that he thought and said that the word "quack" as used in this article referred to Dr. Tucker, the plaintiff's brother, and of course if that is so, if it refers to the inventor of this specific and not to the person who sells it in this country, it is quite plain, and my learned friend would not contend that he would be entitled to rely upon that word, because the plaintiff is here claiming damages for himself for something which is said about him, and he cannot complain nor can he ask damages for anything that is said about his brother. This is the letter which my learned friend read of the 9th May, 1907, which the solicitor wrote, and he says in that letter that this paragraph "has very recently come to his notice." That is on the 9th May. Then he goes on to say, "Our client is the general manager in England for Dr. Tucker and has a considerable personal and direct interest in the sale and distribution of the atomiser and specific. The statement with reference to the inquest and to the sale of the inhaler (or atomiser) and the spraying material (or specific) that Dr. J. F. Waldo, the coroner, rightly stigmatised this kind of dealing as a fraud and the use of the word quack in connexion with Dr. Tucker are subject of very serious complaint by our client." So it is quite plain that the plaintiff's solicitor himself read this article as though the imputation arising from the word "quack" was an imputation upon Dr. Tucker of Mount Gilead, Ohio, or wherever he lives, and not on the plaintiff. I will ask you to consider these matters when you come to consider the libel, not that in my judgment they are very material, because the essence and sting of this libel is, according to my learned friend's case, that the word "fraud" is used with reference to plaintiff's course of dealing, and with that I am perfectly content to deal.

Now you will also notice that this paragraph standing by itself makes reference only to the plaintiff's course of dealing as evidenced by what occurred at the inquest, and if both parties had been content to try this case upon that fact alone of course this inquiry would not have taken the time that it has. I should have been quite content to take your judgment if the plaintiff had been willing that it should be so taken upon the question connected with that inquest as relating to the plaintiff's course of dealing, because what do we know those facts to be? We know that a man earning weekly wages died of long-standing consumption in the year 1906. We know that two years previously he had paid a sum of money which to him must have been a large sum for a specific which, according to the plaintiff's own statement before you, was not intended to do him good and could have done him no good, and, what is more, that it was supplied to him when the plaintiff himself had information in his own possession which if he had chosen to look at it would have indicated to him that this man was suffering from a disease for which his specific would be of no assistance, and yet he took that man's money. Why do I say that? You remember the questions that that man Cushing was told to answer when he applied for the specific. One of these questions—I shall have to deal with the questions later—said: "What remedy are you in fact using to relieve attacks? Answer: Cod-liver oil as tonic." I said to Mr. Tucker as you remember: "Did not the fact that this man was taking cod-liver oil as a tonic indicate to you that he was possibly or probably suffering from such a disease as consumption?" His answer was: "It did indicate to me that the man was in a run-down state." I asked him: "Would not that fact indicate to you that he was possibly or probably suffering from consumption?" and his answer was "Yes"; so you find a man with the knowledge in his possession that this man is suffering from a disease which he himself admits this specific does not cure, and will not assist, taking that man's money and taking what for him is a large amount, impoverishing him to enrich himself. I venture to say that anybody criticising that state of things alone would be entitled to use as strong language as his vocabulary admitted. But bear this in mind; the plaintiff is not content that his kind of dealing should be judged by that circumstance alone, and he comes before you and says in substance: "It is not fair you should judge my kind of dealing by the case of Cushing alone." Before I pass from the case of Cushing I want you to bear in mind that the facts are proved here beyond contest, and Mr. Tucker has offered no explanation of how it was or why it was he supplied this specific to him or what possible justification there was for so doing; not a word. Therefore he cannot come into any court of justice; he cannot come and ask any jury to say that the strongest language is not warranted with regard to that case. He comes here, therefore, before you and says: "Do not judge me, gentlemen, upon that one case alone. I bring before you these facts: I bring before you the fact that I supplied this treatment on a fortnight's trial," from which he desires profession are using and recommending a specific in imitation of Tucker's specific as a specific for asthma. Do not you think it is a scandalous thing that Mr. Tucker should be charged with fraud for selling that specific?—I am not prepared to express an opinion as regards the meaning of fraud from the legal point of view.

Mr. DUKE: Very well, that is the only answer you can give me.

Mr. Justice RIDLEY: What you mean to say is what you have said, which is quite intelligible to me.

Mr. ELDON BANKES: It is no good objecting to my learned friend because he persists in putting this question to the witnesses, but I think the jury by this time understand that it is a question for them, and I suppose they will not be affected by these questions.

Mr. Justice RIDLEY: It is a great pity we have ever got such a question at all. If the people had actually written what they have said in court there would not be much bother about it, but fancy people writing this. Either they do not mean it or they do not know what it means. These things which they have written are not a part of this gentleman's evidence and not a part of most of the evidence relating to your case, which is, that it is dangerous to circulate cocaine without medical supervision. That is quite a different point.

Re-examined by Mr. ELDON BANKES.—You have been asked what other doctors do about cocaine.

Mr. Justice RIDLEY: One can accept that with great respect and refrain from expressing any divergence of opinion.

Mr. ELDON BANKES: I understand you to say that no doctor should prescribe cocaine.

Mr. Justice RIDLEY: He goes a little further and says no cocaine at all.

The WITNESS: No cocaine internally.

Mr. ELDON BANKES: In your experience has there been great alteration in the view of the medical profession with regard to the use of cocaine quite recently?—Very great, particularly in the United States, where the cocaine habit has been specially developed.

And do you find also in England, to some extent but not to the same extent, an alteration of feeling?—I think so, yes.

Mr. SAMUEL ARCHIBALD VASEY, *examined by* Mr. ELDON BANKES.—You are a Fellow of the Chemical Society, a Fellow of the Institute of Chemistry, a Member of the Society of Public Analysts and an analytical chemist, and I think you have had 20 years' experience?—Yes, that is so.

You now direct the work of THE LANCET laboratory?—Yes, that is so.

And you act as general consulting chemist to the proprietors of that paper?—Yes.

Have you analysed different samples of Dr. Tucker's liquid?—I have.

You could recognise the bottles? Do you wish me to identify them, Mr. Duke?

Mr. DUKE: No, I shall take the witness's evidence; it is merely a matter of form.

Mr. ELDON BANKES: How many analyses have you made?—In all, two.

Mr. Justice RIDLEY: Two bottles?

Mr. ELDON BANKES: I only want the approximate dates of the analyses.—The first one was examined on July 4th, 1907.

I think that was a small quantity of liquid remaining in a bottle and the other was of a full bottle?—Yes, that is so.

What was the date of the second analysis?—July 5th, 1907.

Was the second analysis rather fuller than the first because you had more liquid to deal with?—That is so.

Mr. Justice RIDLEY: Can you give us the analyses?

Mr. ELDON BANKES: Yes, I can. It is only to show the variation.

Did you find the same active constituents in each case?—Yes, I did.

You found cocaine in each, did you?—Yes

In the first one how many grains per fluid ounce?—Of cocaine, 1·03.

In the first one?—In the first one.

And in the second one?—1·47.

Did you find atropine?—Yes.

In the first how much?—0·52.

And in the second one?—0·66.

Did you find sodium nitrite in each?—Yes, in the first one 16·00 grains and in the second 24·46 grains.

Mr. Justice RIDLEY: Are these all in grains which you are giving?—Grains per fluid ounce.

Mr. ELDON BANKES: I think you found considerable quantities of glycerine in each?—Yes.

And oily matter?—Yes.

I think there was nothing else which it is material to mention, was there?—No. I think not.

Mr. Justice RIDLEY: In the other analysis which we have been dealing with there was 2·28.

Mr. ELDON BANKES: Yes, your lordship will see there are great variations between the different bottles of liquid.

Mr. Justice RIDLEY: That is more than double the first sample taken here?

Mr. ELDON BANKES: Yes.

Mr. Justice RIDLEY: And the figures that you have been dealing with are twice too much?

Mr. ELDON BANKES: Not twice too much but it shows the great difference between the two samples.

Mr. Justice RIDLEY: On the other hand the atropine was more?

Mr. ELDON BANKES: Yes.

I think you also made some investigations with regard to the atomiser?—Yes, I have.

Will you please hand in the four which you have dealt with? I think for the purposes of this case it is quite sufficient for me to deal with four. There is Mr. Tucker's own atomiser, there is Oppenheimer's atomiser which Mr. Tucker produced, and there were two which I put to Mr. Tucker as coming from Mr. Rogers.

Mr. Justice RIDLEY: He has found some that will produce vapour.

Mr. ELDON BANKES: I am only dealing with the four which Mr. Tucker dealt with and he admits that all those four produce equally good vapour, but his complaint about them was that they did not produce as much. I just want to identify the four.

There are the two of Mr. Rogers' and there is Mr. Tucker's and there is Oppenheimer's (handing same to the witness). Have you made tests with those to see the quantity of the liquid which is atomised in a given number of compressions?—I have.

So as to see the volume of vapour which each one will produce with a given number of compressions?—The weight of vapour.

With you please give us the result?—With Messrs. Oppenheimer's we found that 100 compressions of the bulb gave 0·48 grain of spray. Am I to give the figures of Mr. Tucker's?

Yes, if you please.—With Mr. Tucker's 100 compressions of the bulb gave similarly in the same hands 0·60 grain of spray.

As to the atomisers of Mr. Rogers, have you them here? Those which you have are the ones which were put to Mr. Tucker, are they not?—Yes, one with a black bulb, the other with a white bulb. This one, the black bulb with 100 compressions, gave 1·08 grain weight of vapour.

And the white bulb?—The white bulb with 100 compressions gave 1·07 grains weight of vapour.

Did you use them under similar conditions?—Precisely the same conditions.

And the same liquid?—The same liquid and in the same hands.

Is the result of those examinations that Oppenheimer's is slightly less powerful than Mr. Tucker's?—That is so.

To the extent of the difference between 0·48 and 0·60 per 100 compressions?—Yes.

But both the atomisers of Mr. Rogers are more powerful?—Yes.

Do they each produce equally good vapour?—Equally good, yes.

Equally fine spray?—Equally fine and dry vapour.

We have had the prices of those, I think.

Mr. Justice RIDLEY: Not of Mr. Rogers's.

Mr. ELDON BANKES (to the witness): Can you give me the price of Mr. Rogers's?—No.

Mr. ELDON BANKES: Mr. Rogers will tell us that.

Mr. Justice RIDLEY: I have the price of Mr. Oppenheimer's.

Mr. ELDON BANKES: Perhaps my friend will take it from me.

Mr. DUKE: Certainly.

Mr. Justice Ridley: But he justified there.

Mr. Eldon Bankes: Yes, and he said it was a matter of fair comment.

Mr. Justice Ridley: Which you have not ventured to do.

Mr. Eldon Bankes: Gentlemen, justification is not needed if the words come within the region of fair comment. That is what Chief Justice Cockburn points out there, and curiously enough in this case when the case was first tried the learned judge who tried it took the view that if you call a man a "quack of the rankest species" that was accusing him of want of skill and capacity, and that you must justify it or else you must fail; and upon that the jury arrived at a certain conclusion. But the defendant appealed from that because he contended that he was entitled to rely upon the plea of fair comment, and the case went to the House of Lords. I have the judgment of the House of Lords here and I will read you a short passage from the judgment of the Lord Chancellor. It deals not only with this point, but with the point which I understand from my learned friend's opening he desires erroneously to rely upon. That being the statement of the libel the Lord Chancellor said, "In the second place the defendant was in my opinion entitled to have the jury's decision as to the plea of fair comment, whether or not in all the circumstances proved the libel went beyond fair comment on the plaintiff and on the system of medical enterprise with which he associated himself as a matter of public interest treated by defendant honestly and without malice." Why I emphasise these words is this. You see that the Lord Chancellor's statement is that the defendant is entitled to have the opinion of the jury on the facts proved. My learned friend has been more than once indicating to you that the question for you is what did the writer actually know at the time when he wrote? That is not the question. If the plaintiff chooses to bring an action for libel and to bring his case into court the jury have to decide as to whether the comment was fair comment upon the facts proved by them. It is quite immaterial that the writer knew. If he was right and if the jury upon the facts proved before them that he did not exceed the limits of fair comment it does not matter whether that writer was right by accident or by design; the point is not what exactly he knew at the time but the question is, aye or no, upon the facts proved at the trial, was the comment fair or was it not?

Now, gentlemen, that being what I submit is the question before you—whether upon the facts proved before you the writer could honestly come to the opinion which he has expressed here—let me ask you to consider again what this writer says and whether it is not obvious that this writer is speaking of a matter of his opinion and is not stating a fact as a fact. The words are quite short. You will see what the writer says: "Dr. Waldo, the coroner, rightly stigmatised"—now what?—"this kind of dealing as a fraud." What is the meaning of the word "stigmatised"? I suppose the only meaning is that he branded it, but whether you use "stigmatised" or whether you use "branded" or whether you say the coroner "called it" or whether you say the coroner stated that "in his opinion it was" it is equally immaterial. It is quite plain that the coroner was not speaking of the man but he was speaking of the man's dealing. It is quite true that the man's character may be involved in his dealing, but he is speaking of the man's course of dealing and he is expressing his opinion of his course of dealing, and the writer of this article is saying, "In my opinion the coroner was right"; both the coroner and the paper are stating that in their opinion this course of dealing was a fraud. I say that if you think that that opinion may have been honestly held it may be fearlessly expressed and it does not exceed the limits of fair criticism, and it is not a correct view of the law to say that if you say that a man's course of dealing is fraudulent you must prove it offhand. Let me ask you to remember for a moment what is meant by the word "fraud." Of course, there are technical meanings of "fraud" and there is a meaning of "fraud" in the sense in which it is not usually used by the public generally. There are differences in fraud. There is legal fraud and there is moral fraud; there is criminal fraud and there is fraud which makes a man responsible for damages. One knows what criminal fraud is; a criminal fraud is clearly defined. For instance, I suppose obtaining money by false pretences is a criminal fraud. Fraud in relation to an action for damages has been often defined It may be an actually dishonest statement or it may be a statement made recklessly without knowing whether it is true or false. Those are definitions, but how does the ordinary man use the word "fraud" and how does the ordinary reader who is reading a newspaper understand the word "fraud"? Does not everybody habitually use the word "fraud" in a general sense, as meaning that the thing of which he is speaking is calculated to mislead and is deserving of severe censure? Is not that the ordinary meaning of the word "fraud"? And can I give a better illustration of that than has occurred in this case and has fallen from my learned friend? This is introducing a matter which I must deal with rather out of its logical order, but I want to deal with it and I want to deal with it at this moment because of what my learned friend said about it. You will remember that Messrs. Oppenheimer's specific has been introduced into this case. Of course, it has been introduced into this case for the purpose of leading you to suppose that what Oppenheimer does Mr. Tucker can do, and that the two things are practically identical, and therefore that what Oppenheimer has done ought not to be called fraudulent or dishonest. I hold no brief for Mr. Oppenheimer but I can point out to you what seemed to me to be a very material distinction between the two cases. Our complaint here is that this specific is sold by Mr. Tucker indiscriminately to the general public without any warning, and indeed with directions that it is harmless and that it may be used or should be used as often as possible—the direct contrary to what ought to be the instructions accompanying this dangerous liquid. Oppenheimer's are chemists; they prepare this specific, they sell it to physicians and chemists, they sell it only to qualified men, and accompanying the sale is the statement in their catalogue of what it contains. Therefore they are telling skilled people that what they are selling is dangerous. They label the bottle; they put on the bottle "Poison." They accompany it with directions on the bottle. I have not the bottle here but I can find you exactly what it says; the bottle says, "Poison; not to be swallowed; must only be used with an aeriser or vaporiser." Then in print, "To be used as directed by the physician." Then it says, "In compliance with the Sale of Poisons Act, this preparation is labelled 'Poison' but nevertheless is perfectly safe if inhaled by means of the aeriser or vaporiser." First of all they send it out to people who are qualified people, telling them what it contains; they put on the bottle a notice indicating to everybody that it is only to be used as directed by the physician—that is to say, it is only to be given in a proper case and it is to be only used in the quantities directed by the physician. It would appear to me to be obvious that there are distinctions between that case and this case and they emphasise better than anything I can say to you the distinction between what I suggest to you is a legitimate dealing in such a liquid as this and an illegitimate dealing; but please bear this in mind, I am *not setting up* Oppenheimer's as being the right thing *to do*, as over and over again you have heard from my witnesses that they would apply the same language to Oppenheimer's as they have done to Mr. Tucker if the liquid were sold under the same circumstances. Therefore please do not be misled by this incident of Oppenheimer but see it in its real light, and when you see it in its real light you will see it has got nothing in the world to do with the case, because it is not the constituents of the specification of which we are complaining but it is the way in which it is indiscriminately disseminated with most misleading directions as to its qualities and its use.

But now I am coming to the point as to which I told you I wanted to use this in connexion with the word "fraud." You will remember my learned friend Mr. Duke in opening this case rather indicated that he was going to attack the coroner for making observations about people when they had no opportunity of answering it. I will just call your attention to what Mr. Duke said about Oppenheimer and their treatment. He says to the witness, Dr. Willcox, "Read it out, please"—that is to say, read it out from the catalogue. "Many inquiries from important medical men having reached us regarding a certain preparation for asthma recommended by an American doctor, we introduced our Neboline compound, No. 21, which is similar in every respect to the preparation in question and which from the reception accorded to it seems to meet all requirements." You will see that Mr. Duke had got in his mind that Oppenheimer had been doing a thing which was not quite according to his view, "cricket," if I may use that expression—it was not quite right of them; they had been copying Mr. Tucker, a thing which deserves severe condemnation.

Mr. Duke: I did not so suggest; certainly not.

to you that I did to the plaintiff when I checked them calling their witnesses. I know the old advice I used to get —I used to be told not to call any witnesses more than I could help.

Mr. ELDON BANKES: I feel that in the exercise of my discretion I ought not to go on calling more witnesses than I think is necessary. I feel that I have called really as many eminent men as I ought to call, and therefore the only question is that I may have one or two other witnesses, but they are not present here at the moment. Would your lordship allow us to adjourn now? I will undertake not to call any more medical witnesses, and the two witnesses I want to call, if I can get them, are quite short, but they are not here now.

Mr. Justice RIDLEY: What are they to prove, if one may ask without being inquisitive?

Mr. ELDON BANKES: One is a special witness and I will not refer to him at the moment because I am not sure whether I am going to call him; the other witness I want to get is a gentleman of the Bar to prove the American law with regard to the sale of poisons.

Mr. Justice RIDLEY: I can see that it would be totally immaterial.

Mr. ELDON BANKES: Your lordship will rule on that when the time comes

Mr. Justice RIDLEY: You charge a gentleman with fraud in this country and you want to prove what the American law is.

Mr. ELDON BANKES: This gentleman has given us a good deal of evidence about the sale of this specific in America. Our case is that it is dangerous, and as evidence of that we desire to give evidence of what the law is in those particular places where this gentleman has chosen to say there is an enormous sale.

Mr. Justice RIDLEY: That will not prove the fact that there is *an enormous sale*.

Mr. ELDON BANKES: No, but it will be very strong evidence, surely, that it is regarded as dangerous, not only by our doctors but by the doctors in America who are vouched by the other side.

Mr. Justice RIDLEY: There are a great many patent medicines which are consumed in enormous quantities in this country which are *regarded as dangerous* by the medical profession, but their consumption has not decreased, and it never will, in my opinion.

Mr. ELDON BANKES: Your lordship will remember the evidence of the last witness, Professor Cushny. He said they had gone a great deal further with regard to cocaine in America than we have. What I seek to prove is that the sale of this actual specific is actually forbidden.

Mr. Justice RIDLEY: Let us see what your libel is in this case. I cannot see what bearing it has upon this.

Mr. ELDON BANKES: It is evidence that these things are dangerous. I do not want to keep up the discussion. I have not the witness here now, and therefore I cannot tender him.

Mr. Justice RIDLEY: You must do as you think proper.

Mr. ELDON BANKES: I will undertake that I will not take any appreciable amount of time with my evidence on Monday.

Mr. Justice RIDLEY: Then I suppose we must adjourn.

Mr. SMITH: Unless there should happen to be a short witness from THE LANCET whom my friend is going to call.

Mr. ELDON BANKES: No; not from THE LANCET.

FOURTH DAY.

Mr. JOHN ARTHUR BARRATT, *examined by* Mr. ELDON BANKES.—I think you are an English barrister, and that you are also a Member of the Bar of the Supreme Court of the State of New York and the Bar of the United States Supreme Court?—Yes; I am. I have practised actually in the United States for 18 years.

Have you been asked to make yourself familiar with what the law of the State of Massachusetts is with regard to the sale of proprietary medicines containing cocaine?—Yes; I have.

Mr. DUKE: I believe that my learned friend now proposes to tender evidence as to the law of the State of Massachusetts upon this matter. I object that no such evidence is relevant in this case. Whatever may be the position with regard to cross-examination upon such topics, I submit it is impossible to make the law of the State of Massachusetts relevant in this case.

Mr. Justice RIDLEY: No. I do not think it is relevant. My opinion is that it is not relevant; but perhaps it would be better to see the evidence. You know what I think the point in this case is.

Mr. ELDON BANKES: If your lordship is strongly of opinion——

Mr. Justice RIDLEY: I think there is no doubt about it. We know what the law is here under the Pharmacy Acts; that is the point really. If it is not material that is an end of it.

Mr. ELDON BANKES: Except that this particular law is stronger.

Mr. DUKE: No. I object to statements whether the law is stronger or weaker. It can only be introduced for the purposes of prejudice.

Mr. Justice RIDLEY: I must ask you to show me how it is relevant, Mr. Bankes. To my mind it is right off the point.

Mr. ELDON BANKES: My submission is this, but I will not argue it if your lordship is against me——

Mr. Justice RIDLEY: I would like to hear you.

Mr. ELDON BANKES: My submission is that our case is that this specific containing these poisons is dangerous.

Mr. Justice RIDLEY: That is not enough; that will not help you. If that is all you lose your verdict.

Mr. ELDON BANKES: It is an element in the case and I submit that this evidence as to the law of a State of New York upon that particular point is relevant.

Mr. Justice RIDLEY: I do not think it is.

Mr. ELDON BANKES: If your lordship says so of course I do not persist in it. That is my case.

Mr. Justice RIDLEY: I will assume that it is contrary to law and that they have a law relating to poisons in the same way that we have. I think it has appeared already in evidence that there is such a law in the United States or in the State of Massachusetts. I rather think that is so, but I forget whether I merely got it through an observation of one of the witnesses.

Mr. DUKE: The plaintiff said that he heard that *one had* been proposed. I omitted before closing my case to put in an answer to an interrogatory.

Mr. ELDON BANKES: *By all means.*

Mr. DUKE: It is answer 2, with regard to the knowledge of the defendant upon the main question, the plea of fair comment.

Mr. Justice RIDLEY: Will you hand it up, please? (Same handed up to his lordship.)

Mr. DUKE: It is question No. 2 and the answer to that question; this is the defendant's answer: "In answer to Interrogatory 2 I made no inquiry as to the truth of the statements set out in the said interrogatory before printing and publishing the said statements and took no steps to test the reliability of the information which I had previously received as to the said statements because such information was derived from (1) a cutting from the *Morning Advertiser* of Wednesday, January 2nd, 1907, and certain printed instructions as to the use of Tucker's asthma specific which said cutting and printed instructions were forwarded to THE LANCET by Dr. F. J. *Waldo*, the coroner, before whom the inquest referred to on the said Cushing was held; (2) the advertisements mentioned in my answer to Interrogatory 4 and my general experience and knowledge in regard to the danger likely to result from following the treatment recommended in such advertisements."

Mr. Justice RIDLEY: They are not advertisements of this specific but of others.

Mr. DUKE: Yes, not of this specific but of large numbers of patent remedies.

Mr. ELDON BANKES: May it please your lordship, gentlemen of the jury. I am sure you must be glad that we are approaching the end of this inquiry and I will not delay you longer than I can help; but in opening this case to you I desired to deal, and did deal, though I am afraid in rather a disjointed manner, with what seemed to me to be matters of general importance in this case which you should bear in mind before I called my evidence. But now my duty seems to be different. I want to get if I can to what I may call closer quarters with what are undoubtedly the material matters in this case: first of all, the libel itself; secondly, the law as applicable to that libel—and I shall deal then I hope satisfactorily with the points which have been indicated to me by my lord more than once during this trial; and *finally*, with the evidence which has been given, because we say it will do harm to persons suffering from kidney disease, from consumption, or bronchitis—all diseases which to the patient very often present the same indications and the same symptoms as asthma. We say it will do harm to these people and we say it will do harm to people who from their temperament or from their surroundings are likely to take too much. To meet our case he ought to have called people of that class to say that they had not been hurt. Then there would have been some substance in this evidence which has been given, but he has selected people who are not likely to be hurt, partly from their character, partly from their surroundings, and mainly from the fact that with one single exception he has not produced before you a single person who consumes any quantities of this liquid at all.

I am going through them quite shortly to justify the statement which I am making but before I do that I want to bring to your minds as far as I can some indication of the quantities of this liquid which people take if they follow the directions which Mr. Tucker has issued. I do not want to go into minute calculations but I think I can put it to you in a few words. You see in his instructions he says that an ounce will last from two to four months. In his evidence in chief he suggests that an ounce would last on an average three months. Of course, if you take an average of the 25,000 people, or whatever the number is, who are using it for three months, and you find that many are taking from 12 to 18 months to consume an ounce, there must be a great many people who are consuming it in a week or two in order to arrive at an average of three months. But there is an answer of the plaintiff's which I should like to look into a little more carefully, because that will be an indication to you as to the quantity which people take. He says this: I was pressing him as to whether he had made any experiments to see how much people did take. "The amount of fluid in the bottle would last at least two weeks of constant using four, five, or six times a day." Let us just follow that out. We have shown that if you use it to the full extent, with ten squeezes for each inhalation, and six inhalations a minute, you will get 300 in a minute. With those 300 compressions we know that you would inhale 1/66th of a grain. If you did that six times a day you would get 1/11th of a grain and if you did it to that extent, instead of taking, as the plaintiff says, two weeks, it would take rather more than three weeks, so that it is plain, according to the plaintiff's own view, that we have under-estimated and not over-estimated the amount which a person takes by this number of compressions. He says that the amount of fluid in the bottle would last at least two weeks using it four, five, or six times a day. Just compare that with the evidence of the people who have been called before you. It is quite true that I did not ask all of them the time that the ounce lasted. I wish I had; but one sees afterwards the importance of questions which one does not ask of all of them. But I asked a good many of them and they told you that their ounce lasted from 12 to 18 months. Just think; compare the case of a man with whom an ounce lasts 12 months or 18 months with the case of a man whose ounce lasts two weeks. You cannot compare the two things.

Mr. DUKE: There is no evidence of any use of an ounce in two weeks, or anything like it. It was a small quantity at the bottom of a bottle which you were asking Mr. Tucker about, and he said: "I look at that quantity in the bottle and I say it will last three months."

Mr. Justice RIDLEY: Yes, three months; there is no evidence that I know of except that he said three months.

Mr. ELDON BANKES: I will read his answer.

Mr. Justice RIDLEY: "The average time for one ounce would be three months by daily use."

Mr. DUKE: You had a small quantity in a bottle.

Mr. ELDON BANKES: I am reading the answer. It may be I am wrong, and if my friend corrects me I will accept the correction; but this is the answer: "Have you made any experiment which will enable you to say the quantity of liquid which is atomised if you follow the instructions here detailed?—The amount of fluid in the bottle would last at least two weeks of constant using four, five, or six times a day." My friend tells me he was not speaking of a full bottle, but he was speaking of a part of a bottle. I will accept the correction. I do not remember it myself, but if that is so I will accept the correction.

Mr. Justice RIDLEY: I have not any evidence about two weeks at all.

Mr. ELDON BANKES: I could have worked it out in a different way, but I have not got the figures for the moment. I have got as far as this, that in one day you take 1/11th of a grain. Therefore you would take 11 days to take a grain. There are 2¼ grains in a bottle, and therefore you would want about 25 days; using it according to the directions of the pamphlet it would take you about 25 days supposing you were able to compress to that extent. But please keep this in mind. It would take 25 days if you were to use it to the full extent indicated on the pamphlet. How can you compare that with a man who is using an ounce in 12 to 18 months? You will remember that I could not go into this because I could not give particular instances, but my learned friend asked Mr. Francis with regard to a patient of his. I could not have done that, but he did it, and the name has been passed down. It has not been made public, and of course it ought not to be made public, but the facts with regard to that case are that Mr. Francis has told you that that man was using it 20 or 30 times a day, and that is a case of the kind of user that does harm. How can it assist you as to whether or not in certain cases this specific does harm to call a number of persons who have not used it to a sufficient extent to do harm and who are not in a position in which it is likely to do them harm. Upon that let me call your attention to this. What kind of person do you think would be most likely to be affected by this stuff? Who is the person who is most likely to be addicted to a too frequent use of it? Is it the busy professional man whose one object is to get relief and go back to his work, and when he gets back to his work he will be engrossed in his work, and he will not think about his horrid complaint until he gets another actual attack; or is it the person sitting at home with nothing to do who dreads these attacks, who takes the stuff to relieve the attack, and sits there wondering when an attack will come again, and takes a dose because he thinks an attack is coming on, and so forth? The great bulk of the people who have been called before you are the busy professional people, the people who are not likely ever to take this to excess. They are not only that, but they are healthy people—I mean healthy in the sense that they are not suffering from any of these diseases. You will remember what Mr. Bateson, the first witness, the barrister, said. I asked him if there was anything the matter with his heart, and he said: "Heart? No, I am passed every year as a first-class life by the insurance office." Those are not the people likely to be injured, and if you run through the list you will see that I am speaking correctly about that. There was Mr. Bateson, a professional man, a barrister; he says he hardly requires it at all now. He used it constantly—I mean constantly in his sense—at one time and he says that the ounce lasted him 12 to 16 months. There were two peers, Lord Ashburnham and the Earl of Harewood. It is true they are not professional men, but they are men with many interests in life who have a great deal to think about and, therefore, I think I may fairly class them for my purpose in that class. I mean they are men who are not sitting morbidly contemplating their ailments, but they have to be out and about because they have so much to do. There is Mr. Coombs, the borough treasurer of Kensington—I refer to his evidence because I notice in his evidence he says he worked the thing at the rate of 10 up to 15 compressions a minute. When I spoke to you before I thought 10 was the highest, but he has got up to 15. There is Mr. Mansfield, the barrister, who for 18 months has used it very little. There is Mrs Stewart, the wife of Major-General Stewart; it is quite true that her husband ought to be put in a different category, because he is a man who has retired and an old man; but my comment upon him is this: it may be that he is a man perhaps of strong disposition and strong temperament, and he is not likely to allow anything to become with him a source of danger. There is Mr. Belfield, the solicitor; Mr. Fort, the master at Winchester; and Mr. Symons, a barrister, who also mentioned that the ounce lasted him from 12 to 18 months. There is Mr. Denton, the commercial traveller, and General Lane. Mr. Pickmeyer, the wine merchant and the active cricketer; Mr. Lowry, the wine merchant, and Mr. Venn, the solicitor; and then came three doctors. I want to say a word about the three doctors.

Mr. Justice RIDLEY: There are some more besides.

Mr. ELDON BANKES: I think I have mentioned them all.

Mr. Justice RIDLEY: There is Mrs. Pimm.

Mr. ELDON BANKES: Yes, she came after the doctors.

Mr. Justice RIDLEY: A very fine specimen.

Mr. ELDON BANKES: A very fine specimen as I was just going to say—a very active woman because she said she had you to come to the conclusion that everybody has a fair chance of taking it or rejecting it. He comes before you and says: "This treatment of mine may have been no good in this instance but I can prove to the jury that it has had extremely beneficial effects in other cases. I desire to tell the jury that I have had 25,000 patients and I have had no complaints; I desire to tell the jury that this was invented by my brother, who is a qualified doctor, and therefore I was justified in assuming that it was all right." So that he is not content to leave the case to be judged upon the case of Cushing but he comes before you and he lays evidence before you which I hope I have fairly summarised in this short summary which I have just given; but of course if the plaintiff wishes to make further statements to you about what his kind of dealing really is, equally the defendant comes before you and says: "Before you can form a true judgment as to whether these words were warranted or not, if we are not to deal with the case on the facts of the Cushing inquest alone you must know the whole facts with regard to this treatment"; and what does the defendant come before you and in substance say? He says: "I want to tell the jury that the view which the plaintiff has presented is only a partial view of this statement; I want to tell the jury that this liquid contains two extremely potent and dangerous poisons; I want to tell the jury that this man is selling those poisons in flagrant defiance of the laws of this country and ignoring all the precautions which the law says must be taken in the interests of the public generally; I want to tell the jury that this specific used as directed by the plaintiff is a great source of danger to the public health; I desire to point out to the jury that this sale is accompanied by statements in the nature of advertisements which are in themselves gravely misleading; I desire to tell the jury that the price charged for this specific under the circumstances under which it is sold is not justifiable; I desire to tell the jury that the way in which this man carries on his business leads people to think that this specific is only sent out under competent medical advice." Those are the additional sets of facts which the plaintiff on the one side and the defendant on the other side have desired to bring before you, and in a moment I shall deal with the question how far those statements on the one side and the other have been proved, and upon those facts of course you will have to say: Does the evidence establish what the defendant says is this plaintiff's real course of dealing? If you find, as I shall ask you to find, that the defendant has established these facts, then the question arises whether in point of fact the language which was used was beyond what the occasion warranted. Now upon that I desire to deal with the points which my lord has more than once put to me in this case, and I will endeavour to explain to you what I understand the law to be. This is a case in which the defendants have not justified; that is to say, have not gone so far as to take upon themselves the burden of proving that the words which they have used are absolutely true. But the position which they take up is this, that this sale by the plaintiff of this specific in these enormous quantities is a matter of public and general interest and so were the events which were proved at that inquest. I am entitled as the editor of a newspaper, or as, indeed, any man is entitled, to comment fairly and freely upon those facts What is fair comment and what does the law allow under the privilege of fair comment? It allows anything that any honest man may think or say, whether you think the thing is exaggerated, whether you think that the view which the man took was prejudiced or not, so long as you think that any honest man might, having regard to the circumstances which are proved before you, think he is entitled to say this, whether you agree with him or whether you do not agree with him.

There are just three cases to which I should like to refer as showing what I mean. The first one, from which I will only read a few passages to you, is the very well-known case of Merivale v. Carson, which is always quoted in this connexion and which is reported, I may say for my lord's convenience, in 20 Queen's Bench Division at page 275. The only distinction between that case and this case which I wish you to bear in mind while I read this passage is this, that this was a criticism of a book or a play and therefore the learned judges used the words "criticism upon the work," but the law is the same and my learned friend would not dispute that it is the same whether it is a book or whether it is a play or whether it is any other incident which may be said to be of public interest and importance. What the learned judges there said is this, and it is Lord Esher's judgment from which I am going to read: "What is the meaning of a 'fair comment'? I think the meaning is this: is the article in the opinion of the jury beyond that which any fair man, however prejudiced or however strong his opinion may be, would say of the work in question? Every latitude must be given to opinion and to prejudice, and then an ordinary set of men with ordinary judgment must say whether any fair man would have made such a comment on the work. It is very easy to say what would be clearly beyond that limit; if, for instance, the writer attacked the private character of the author. But it is much more difficult to say what is within the limit. That must depend upon the circumstances of the particular case. I think the right question was really left by Field, J., to the jury in the present case. No doubt you can find in the course of his summing up some phrases which, if taken alone, may seem to limit too much the question put to the jury. But, when you look at the summing up as a whole, I think it comes in substance to the final question which was put by the judge to the jury: 'If it is not more than fair, honest, independent, bold, even exaggerated criticism, then your verdict will be for the defendants.' He gives a very wide limit, and, I think, rightly. Mere exaggeration, or even gross exaggeration, would not make the comment unfair. However wrong the opinion expressed may be in point of truth, or however prejudiced the writer, it may still be within the prescribed limit. The question which the jury must consider is this: Would any fair man, however prejudiced he may be, however exaggerated or obstinate his views, have said that which this criticism has said of the work which is criticised?" That is the general expression of the law with regard to what fair comment is. I desire to refer to two other cases, one a very recent one, and one an older one, because the older one is very remarkably like this in its facts and because it deals so appropriately with the point which my lord has more than once put to me. That is the case of *Hunter* v. *Sharp* which is reported in Foster and Finlason, the fourth volume, at page 990. The case refers to some newspaper articles about a man named Hunter who was advertising a specific for the cure of lung disease, and curiously enough it was claimed that the specific would cure lung disease by inhalations by means of an atomiser. The newspaper wrote very strong articles about it. They are very long but I need not read them, because Chief Justice Cockburn, who tried that case, puts forward his view of them on page 997 and takes in from the innuendoes. He says that the defendant says that not only is the whole system delusive but that he (that is Mr. Hunter) has put it forward fraudulently and by fraudulent means and articles; so that the same word is used, and in that case defendant did two things; he justified; he said, first of all, "it is true," but secondly he said "whether it is true or not, what I said is only fair comment upon this system as I can prove it to the jury." Chief Justice Cockburn, in summing up, dealt with the question first of all of justification. He said to the jury: "Now you must consider whether these statements are true or not"; and then he says: "But suppose you cannot go that length that will not conclude the case. It will bring the defendant to his second ground of defence which in that event you must consider. Under that head of defence he says that it was a matter of public interest and public concern; that the plaintiff by his advertisements invited people to submit to his system of treatment and that if he, the defendant, really believed it to be a delusion then he had a right to maintain that it was so; and that even if in drawing inferences of imposture and of intention to fall into error, yet if he wrote honestly and with the intention of exercising his vocation as a public writer fairly and with reasonable moderation and judgment he is entitled to the verdict."

I rely upon that as showing that there may be cases in which the word "fraud" is used with reference to a man's course of dealing in which a jury may, if they take that view, hold that it is an expression of opinion as to a man's course of dealing, and if that opinion is honestly held it may be fearlessly expressed. The last case to which I desire to refer is one which I think is very appropriate also, and it is a very recent case; it may be within your memory. It is a case which was tried in these Courts recently of Dakhyl v. Labouchere, in which Mr. Labouchere's paper, *Truth*, had said of Mr. Dakhyl that he was a quack of the rankest species. In that case the defendant justified; he said it was true, and he said also that it was a matter of fair comment.

to whether the person to whom it is sent is going to be benefited or whether he is going to be harmed.

I will pass from that point, and I want to deal now with our third point. We say that this is sent out, in itself harmful in its effects, accompanied by statements which are calculated to mislead. You will remember that those statements are contained in three documents, so far as they are before you; there is the pamphlet, there are the instructions, and there is the circular. What is the first thing that is said? All three emphasise that this liquid is absolutely harmless. Can you conceive anything which justifies stronger language than that? If you believe the evidence of our doctors, is any word too strong for a system under which a man sends out this dangerous stuff, telling people that it is harmless? I should like, if I may, to give you an illustration drawn from what Sir Lauder Brunton said. Of course, he is a scientific man and he referred to alcohol in a scientific sense as a poison. You know, and I know, and everybody knows, that people do take quantities of alcohol without the smallest harmful effects. Many people think it does them a great deal of good. But let me put this to you: Mr. Tucker has said that so safe is this that it may be taken by children of three years old. What would you think of a man who gave a bottle of rum to a child of three and told him at the same time it was harmless? Have you words sufficient to express your indignation at such conduct or to characterise the action of such a man? But the analogy is quite sound. You are telling a child that what, if used in too large quantities, would probably kill it, is absolutely harmless. What distinction can you draw in principle between that man and the man who trades as Mr. Tucker trades? There are other expressions in the pamphlet which have been referred to. There is one particularly which I want to mention. I suggest to you that the pamphlet not only says that the stuff is harmless, but it says that it will cure asthma. A good deal of criticism has been directed to that. Mr. Tucker says: "I ask you to read that as saying, not that it will cure asthma, but that it will relieve an attack of asthma." The question is, how would any honest person read that—how might an honest person read that when he receives the document? You are familiar with the distinctions; he draws the distinction in places between the relief of the attack and the cure. You will remember one passage in which he says: "It reaches the lungs in order to arrest the attack, heal the mucous surfaces, and cure the disease." All I say, and all I desire to say, is that any honest, reasonable man reading that might very naturally, and I could put it a great deal higher, that he would necessarily, come to the conclusion that he claimed to cure it. But whether that is his meaning or not, that is a meaning which it may bear, and any critic criticising that system is entitled to form an opinion upon his reading of that language as ordinarily understood. I submit that I have established that point also.

There are only two other points to which I have to refer and then I have finished about the evidence. One is as to the price. I do not want to go into this in any detail, but you will remember the strong expression is used that it was an exorbitant price, or that it was robbing the public, or words to that effect. You have to take two things into consideration. It is not merely the actual price, but it is the circumstances in which the stuff is sold. It is nothing to those witnesses who have been called for the plaintiff to pay 3 guineas; they do not mind whether it is 3 guineas or 20 guineas, probably, as long as they get relief. But the writer of this article has in his mind the poor people and he calls attention to it. He says this kind of thing attracts the poor people. He was dealing with the case of a poor labourer; and I ask you to carry your minds into the house of any working man at weekly wages and to realise for yourselves the privations that that family would have to undergo in order to raise this sum of £3 to give to Mr. Tucker. They very likely would raise it—we know they do raise it; but is it justifiable to ask a man to raise that sum, with all the surroundings which it means to him, to him and all the consequences which it means to him, unless you have taken some reasonable means to satisfy yourself that he comes within the category of people who would be really benefited? This man does not care. He says he believes, and I will accept his statement, that it is absolutely harmless. But that is not sufficient. Are you justified in taking £3 out of a working man's home simply because you believe that the stuff will not do him any harm? You have to bear that in mind in connexion with the price, and when we come to the price you will remember quite shortly what the figures are. The price of the constituents of the liquid is infinitesimal—about 3*d.* It is sold to the plaintiff at about 2*s.* and he sells it at 8*s.* The price of the vaporiser, or an equally good vaporiser, is about 6*s.* 6*d.*, because I ask you upon our evidence to believe that those vaporisers which were put before you were equally good; they all produce an equally good spray and he admits that they all produce an equally good spray, but his only complaint of the one which he produced was that it was not strong enough. We produced two which upon examination proved to be stronger. My learned friend had some little complaint that he had not had the opportunity of testing them. That evidence was given on Friday and it is now Monday. If he had wanted to challenge that evidence there was plenty of time for him to have done so. He has not done it and therefore I ask you to believe that we have produced vaporisers which produce equally good vapour and are stronger than the plaintiff's, the price of which in this country is from 6*s.* 6*d.* to 7*s.* 6*d.* He sells his at 28*s.* He gets it from America at about 9*s.* without the bottle and the bulb. The result of all this is that his gross earnings in the year are £19,800, I think, of which he sends £5600 to Dr. Tucker in America and the rest is all profit, except the expenses. What do those expenses come to? He has told you it is about £1000 a year for his staff and something for his agents, but we do not know how much. He has no means of enabling us to judge and he has no means of judging for himself what the actual profit is, but he says that for the purposes of the income tax he puts it at 33 per cent. Bearing in mind that he pays £5600 to Dr. Tucker, the brother, that he pays £1000 for assistance—that is £6600—and that on the top of that he has to pay the agents, whatever it is, and that he has only got the expense of the bottles and bulbs on top, it is a very generous estimate to himself to say that he is making only 33 per cent. I do not care what he makes. We know what they can be sold at and if he does not choose to carry on his business so as to be able to sell them at that price to the ordinary Englishman it is equally true to say that he is selling these things at an exorbitant price, and at an exorbitant price which, having regard to the fact that he takes no pains to ascertain whether *this* stuff is going to do harm or good, does justify as strong language as anybody can find in the English vocabulary.

I have finished our evidence and I ask you to say that we have established, when you know the whole story of this sale, a case upon which severe comment is justified and that we have not exceeded the limit of what any honest man might say under the circumstances of this case. I will not occupy you more than a minute, but I want just to conclude with a word about damages. Of course, you may take a contrary view. I do not know in the least what view you *do* take. I respectfully submit to you that we have made out that this comment is not in excess of what may be called for, but as counsel for the defendants I am bound to deal with the case as a whole, and I am bound just to touch upon the question of damages. Upon that all I have to say is this: This is not the case of a man who has suffered any pecuniary loss at all. You will remember this libel was in March, 1907. His sales during 1907 are higher than they were in 1906, although since May he has kept out of the returns the amount he has paid to the agents. Therefore, if that is any considerable amount his sales are considerably higher in 1907 than they were in 1906. He has suffered no actual damage, but he comes here to ask for your verdict. You will, I am sure, if you give a verdict to him, give him a verdict which, under all the circumstances, you think he deserves. But, gentlemen, I ask you not to give him a verdict which will be the very finest advertisement which he can possibly have for this system of trading unless you think that the system of trading is absolutely without reproach. I ask you to say that if you think that the defendants have in substance established what they desire to say about this treatment, though possibly in your view they have not expressed their condemnation in right language—if that is your view of this case the verdict you ought to give to the plaintiff ought to be measured by the smallest possible amount of damages, and you will only give to him substantial damages if you wish it to go forth to the public that this sale by him, conducted by him, is legitimate, that it is safe, that it is not one which justifies any comment in such a sense as we have passed upon it. In conclusion, all I want to you to come to the conclusion that everybody has a fair chance of taking it or rejecting it. He comes before you and says: "This treatment of mine may have been no good in this instance but I can prove to the jury that it has had extremely beneficial effects in other cases. I desire to tell the jury that I have had 25,000 patients and I have had no complaints; I desire to tell the jury that this was invented by my brother, who is a qualified doctor, and therefore I was justified in assuming that it was all right." So that he is not content to leave the case to be judged upon the case of Cushing but he comes before you and he lays evidence before you which I hope I have fairly summarised in this short summary which I have just given; but of course if the plaintiff wishes to make further statements to you about what his kind of dealing really is, equally the defendant comes before you and says: "Before you can form a true judgment as to whether these words were warranted or not, if we are not to deal with the case on the facts of the Cushing inquest alone you must know the whole facts with regard to this treatment"; and what does the defendant come before you and in substance say? He says: "I want to tell the jury that the view which the plaintiff has presented is only a partial view of this statement; I want to tell the jury that this liquid contains two extremely potent and dangerous poisons; I want to tell the jury that this man is selling those poisons in flagrant defiance of the laws of this country and ignoring all the precautions which the law says must be taken in the interests of the public generally; I want to tell the jury that this specific used as directed by the plaintiff is a great source of danger to the public health; I desire to point out to the jury that this sale is accompanied by statements in the nature of advertisements which are in themselves gravely misleading; I desire to tell the jury that the price charged for this specific under the circumstances under which it is sold is not justifiable; I desire to tell the jury that the way in which this man carries on his business leads people to think that this specific is only sent out under competent medical advice." Those are the additional sets of facts which the plaintiff on the one side and the defendant on the other side have desired to bring before you, and in a moment I shall deal with the question how far those statements on the one side and the other have been proved, and upon those facts of course you will have to say: Does the evidence establish what the defendant says is this plaintiff's real course of dealing? If you find, as I shall ask you to find, that the defendant has established these facts, then the question arises whether in point of fact the language which was used was beyond what the occasion warranted. Now upon that I desire to deal with the points which my lord has more than once put to me in this case, and I will endeavour to explain to you what I understand the law to be. This is a case in which the defendants have not justified; that is to say, have not gone so far as to take upon themselves the burden of proving that the words which they have used are absolutely true. But the position which they take up is this, that this sale by the plaintiff of this specific in these enormous quantities is a matter of public and general interest and so were the events which were proved at that inquest. I am entitled as the editor of a newspaper, or as, indeed, any man is entitled, to comment fairly and freely upon those facts. What is fair comment and what does the law allow under the privilege of fair comment? It allows anything that any honest man may think or say, whether you think the thing is exaggerated, whether you think that the view which the man took was prejudiced or not, so long as you think that any honest man might, having regard to the circumstances which are proved before you, think he is entitled to say this, whether you agree with him or whether you do not agree with him.

There are just three cases to which I should like to refer as showing what I mean. The first one, from which I will only read a few passages to you, is the very well-known case of Merivale v. Carson, which is always quoted in this connexion and which is reported, I may say for my lord's convenience, in 20 Queen's Bench Division at page 275. The only distinction between that case and this case which I wish you to bear in mind while I read this passage is this, that this was a criticism of a book or a play and therefore the learned judges used the words "criticism upon the work," but the law is the same and my learned friend would not dispute that it is the same whether it is a book or whether it is a play or whether it is any other incident which may be said to be of public interest and importance. What the learned judges there said is this, and it is Lord Esher's judgment from which I am going to read: "What is the meaning of a 'fair comment'? I think the meaning is this: is the article in the opinion of the jury beyond that which any fair man, however prejudiced or however strong his opinion may be, would say of the work in question? Every latitude must be given to opinion and to prejudice, and then an ordinary set of men with ordinary judgment must say whether any fair man would have made such a comment on the work. It is very easy to say what would be clearly beyond that limit; if, for instance, the writer attacked the private character of the author. But it is much more difficult to say what is within the limit. That must depend upon the circumstances of the particular case. I think the right question was really left by Field, J., to the jury in the present case. No doubt you can find in the course of his summing up some phrases which, if taken alone, may seem to limit too much the question put to the jury. But, when you look at the summing up as a whole, I think it comes in substance to the final question which was put by the judge to the jury: 'If it is not more than fair, honest, independent, bold, even exaggerated criticism, then your verdict will be for the defendants.' He gives a very wide limit, and, I think, rightly. Mere exaggeration, or even gross exaggeration, would not make the comment unfair. However wrong the opinion expressed may be in point of truth, or however prejudiced the writer, it may still be within the prescribed limit. The question which the jury must consider is this: Would any fair man, however prejudiced he may be, however exaggerated or obstinate his views, have said that which this criticism has said of the work which is criticised?" That is the general expression of the law with regard to what fair comment is. I desire to refer to two other cases, one a very recent one, and one an older one, because the older one is very remarkably like this in its facts and because it deals so appropriately with the point which my lord has more than once put to me. That is the case of *Hunter* v. *Sharp* which is reported in Foster and Finlason, the fourth volume, at page 990. The case refers to some newspaper articles about a man named Hunter who was advertising a specific for the cure of lung disease, and curiously enough it was claimed that the specific would cure lung disease by inhalations by means of an atomiser. The newspaper wrote very strong articles about it. They are very long but I need not read them, because Chief Justice Cockburn, who tried that case, puts forward his view of them on page 997 and takes in from the innuendoes. He says that the defendant says that not only is the whole system delusive but that he (that is Mr. Hunter) has put it forward fraudulently and by fraudulent means and articles; so that the same word is used, and in that case defendant did two things; he justified; he said, first of all, "it is true," but secondly he said "whether it is true or not, what I said is only fair comment upon this system as I can prove it to the jury." Chief Justice Cockburn, in summing up, dealt with the question first of all of justification. He said to the jury: "Now you must consider whether these statements are true or not"; and then he says: "But suppose you cannot go that length that will not conclude the case. It will bring the defendant to his second ground of defence which in that event you must consider. Under that head of defence he says that it was a matter of public interest and public concern; that the plaintiff by his advertisements invited people to submit to his system of treatment and that if he, the defendant, really believed it to be a delusion then he had a right to maintain that it was so; and that even if in drawing inferences of imposture and of intention to fall into error, yet if he wrote honestly and with the intention of exercising his vocation as a public writer fairly and with reasonable moderation and judgment he is entitled to the verdict."

I rely upon that as showing that there may be cases in which the word "fraud" is used with reference to a man's course of dealing in which a jury may, if they take that view, hold that it is an expression of opinion as to a man's course of dealing, and if that opinion is honestly held it may be fearlessly expressed. The last case to which I desire to refer is one which I think is very appropriate also, and it is a very recent case; it may be within your memory. It is a case which was tried in these Courts recently of Dakhyl v. Labouchere, in which Mr. Labouchere's paper, *Truth*, had said of Mr. Dakhyl that he was a quack of the rankest species. In that case the defendant justified; he said it was true, and he said also that it was a matter of fair comment.

know the facts of the particular case. The business of the judge in these courts, as I said a long time ago, is to tell us what the law is, and I hear from my lord——

Mr. Justice RIDLEY: I cannot myself distinguish the speech made by Mr. Bankes from the speech which he would have delivered if there had been a justification upon the record, except on this point where he argued very pointedly to the jury as to the meaning of the word fraud and as to its application to the system and not to the man who carried on the system.

Mr. DUKE: I follow.

Mr. Justice RIDLEY: It will be for the jury to say which is the right view of this matter.

Mr. DUKE: We get to that now, that if the defendant has thought fit to attack the personal character of the plaintiff and to charge him with fraud, if it is not true that the plaintiff is a fraudulent person then the defendant must make amends to the plaintiff; and I said that this case was aggravated by what had taken place in the trial, because every doctor who was put into the box went into the box with the intention not of discussing a matter of public interest but of striking down Mr. Tucker and of destroying Mr. Tucker. My learned friend's speech when he opened this case, and every question he has asked in the course of the case, and the long speech with which he summed it up, have been aimed at destroying Mr. Tucker, at making you believe that Mr. Tucker is a dishonest and unworthy man who ought to be held up to opprobrium, and that it is a misfortune of the defendants that they have not put it here plainly on the record that he is a dishonest man. They did not venture to say it. They had months to decide whether they would say that he was a dishonest man and they did not dare to put it on the pleadings, but they bring a multitude of eminent expert witnesses and my learned friend, and they seek to do by a side wind what they did not dare to do on the pleadings. Is it true to say that Mr. Tucker has behaved like a dishonest man with regard to this remedy? You have heard all there is about it. You know how it came into existence; you know what he has done with it; you know the benefits which have been derived from it. It is not true and it is not fair; and I am going to deal with the two questions together, as in fact the defendant has had to deal with them. Knowing it is not true he has said, if it is not true it is a thing a man might honestly say about him. I am going very shortly to deal with the case upon that footing. Let us see what was being dealt with. You had got here a disease which is a grievous burden upon people who are afflicted, which disables them. It does not kill them, but it disables them; it takes a man in his employment, takes him in his bed, takes him as may happen on any occasion and prevents him from living the ordinary life, from drawing his breath, and puts a weight upon him, and a burden upon him, and he cannot get his breath. You have seem them, I daresay, struggling painfully to get the breath. A man knows if he could gets his breath and relieve that disability of the lungs he would be right again. You have it arising in people who are otherwise in strong health at times, but asthma takes them in that spasmodic way. You have the medical profession failing; during all the generations which the medical profession has had to deal with the matter it has failed to deal with it by any prompt and efficacious means, and that is confessed by the medical men whom you have seen in the witness-box. Down to this time they have been content to go on with old methods which fail in the multitude of cases as they failed in the cases which you have had before you to relieve the ailment. I called before you ten or a dozen, perhaps, of patients out of 25,000 who have testified to the benefits of this remedy, who have been Mr. Tucker's real advertisement. I have called them before you and they have come here and told you: "Our life has been changed by this specific. We were subject to this disabling malady; we are not subject to it now, we are masters of it because here there is this specific which if you get into your lungs checks the attack. and that sets you free to go about your business." An objection is made that I do not call all of them. Do you remember how eager my learned friend was that I should not call any more? Do you remember how he suggested to me what he was willing to admit, and how I thought that, at any rate, those who were here in court had better come before the jury, and the jury had better see them. My learned friend did not want to see them. You had that disease of asthma, you had that condition of things in the medical profession that they had failed to grapple with it, then you had this remedy and this remedy did grapple with it. I do not know whether it could have a higher recommendation than it got out of the mouth of Dr. Francis who was called by the defendants when he said that he knew of no remedy which supplied such immediate relief in the case of asthma as this specific of Mr. Tucker. That was Dr. Francis's own statement. So you have it that the disease is almost universal, the failure of the medical profession virtually confessed by large numbers of medical men who have come here to join in the attack by which Mr. Tucker is to be hounded down and prevented from curing asthma which doctors failed to cure, and you have the Tucker's specific. What THE LANCET people knew about it was as every medical man, and every man of common sense knows, that there was the disease, that there was the failure to find in the pharmacopœia the remedy. Did THE LANCET know that Mr. Tucker had found a remedy? Had they become aware, as Oppenheimer's had become aware, and as the doctors had become aware, that where the old-fashioned medical skill had failed Dr. Tucker had succeeded—that his sufferings for ten years and his medical knowledge operating together had solved this difficulty? Did THE LANCET know it—and that public attention was being directed to it, that asthmatic people were getting to hear from their friends: "Well, the doctors cannot cure you, but Tucker's specific can, and Tucker's specific can drive off these attacks"? Had they become aware of that? It is exceedingly likely they had. Oppenheimer's had been putting in that book which was produced here a catalogue of drugs sold by wholesale without any restrictions of the Pharmacy Act, without any interference of the law, an advertisement of a specific which the doctors say is obviously an imitation of Tucker's but is not so good. That is what their doctors say. They say in their advertisement of it: "We have compounded this because of great numbers of applications we have been getting about it from esteemed members of the medical profession; we have published to meet that demand, and we are able to tell you that we believe it will produce the same results"; and they send it out. Do you suppose that when a medical man has supplied his patient with the fluid once, and that patient has got an atomiser once, if in fact the atomiser does produce a vapour which relieves the attack of asthma, that patient is ever going to refrain from the use of that as long as he is subject to attacks of asthma? It is not common-sense to suggest it, and it does not seem to me that it can be honestly suggested. That is the position—great knowledge in the country of which we have become aware to some extent in the last few days, 300 declared doctors, doctors who have sent as doctors to Mr. Tucker to get this specific, with Sir Stephen Mackenzie, an eminent specialist, at their head (who happens to be on the continent just now, or he would have adorned the witness-box), with the two or three doctors I have had to call on this charge of fraud—all these doctors using and presumably recommending this specific, Oppenheimer's introducing a specific and selling it as the same in effect, although the medical witnesses here say: "No, it is not as good as Tucker's, it is not as effective." And Oppenheimer saying with regard to that specific that it is perfectly safe: "In compliance with the Sale of Poisons Act this preparation is labelled 'Poison,' but nevertheless is perfectly safe if inhaled by means of the aeriser or vaporiser." That is Oppenheimer's attempted copy and that is the state of the case when THE LANCET comes to publish this attack on Mr. Tucker and, of course, it is very material with regard to the question of the damages which you ought to give to Mr. Tucker in this case to see what skilled people knew about this before they let themselves loose to destroy Mr. Tucker by stigmatising him as a fraudulent person. It is material to see that the medical profession was aware of the benefits of his remedy, was aware that large numbers of persons were using it beneficially, was aware that wholesale druggists were putting up a compound in imitation, not by way of invention, but by way of imitation, and that was adding to the use of this specific. That is what they knew if they knew anything about the public part of this matter before they set out to attack and to destroy Mr. Tucker. It makes their attack more serious. There are certain things they are entitled to do. They are entitled next week to publish an article and say: "We believe that this composition of Dr. Tucker's contains cocaine and atropine in small quantities but those are drugs which if they are taken in quantities which we could mention are poisons and have deleterious

Mr. ELDON BANKES: Let me read his question. I have read you what he read from the catalogue, and this was his question: "A very fraudulent transaction, is it not?"

Mr. DUKE: I think my learned friend must know quite well that I was putting to the doctor, who had come here to say that Mr. Tucker's was a fraudulent transaction, that he was in the position, if he was consistent, of having to say that that sale of a thing by Oppenheimer must be in the same category. There is no attack upon their commercial integrity.

Mr. Justice RIDLEY: Yes; it must have meant that.

Mr. DUKE: It meant that if Tucker's was a fraud Oppenheimer's was a fraud.

Mr. Justice RIDLEY: That is how I understood it. I remember it.

Mr. ELDON BANKES: I am sorry if I misunderstood my learned friend, and we must accept this explanation.

Mr. Justice RIDLEY: Of course he meant that.

Mr. ELDON BANKES: It seemed to me so at the time, and when I read it I was more convinced that my learned friend was using that expression with reference to Oppenheimer's because he considered that it was a matter which deserved condemnation.

Mr. Justice RIDLEY: Dr. Waldo said: "Oppenheimer is fraudulent also if he says that"; he accepted it.

Mr. ELDON BANKES: No, that came much later your lordship will find.

Mr. Justice RIDLEY: I know it is a little bit later, but that shows what the coroner meant.

Mr. ELDON BANKES: I will not discuss it. Gentlemen, I was only using it as an illustration, it really was not necessary for my purpose to use it as an illustration but it was convenient to use it as an illustration. My friend says I am mistaken.

Mr. DUKE: Absolutely.

Mr. ELDON BANKES: Therefore I say nothing more about it. It is sufficient for my case to appeal to your common sense as to whether the word is not rightly used in the sense which I have indicated to you, that it is a misleading transaction, a transaction which deserves severe condemnation. Within your own knowledge there must be heaps of instances in which you have heard the word "fraud" used without imputing moral dishonesty and without imputing a criminal offence; and I do not know whether you have not habitually used it so yourself. I can give you heaps of instances. Is it not common knowledge that with reference, for instance, to the sale of articles by the coupon system, that system has been denounced in trade journals and everywhere to everybody's knowledge as a fraudulent system—fraudulent because it deceives the public—fraudulent because it induces servants to buy things which otherwise are not needed in the household, and so on? It is not necessary that I should give you instances, but I can appeal to your common knowledge and common experience to multiply instances in which the word "fraud" is used in that sense and is so accepted and so understood.

If I am right so far, that this article fairly read is an expression of the writer's opinion as following Dr. Waldo upon the system of dealing of the plaintiff, if I am right in suggesting to you that the word "fraud" can be read, and ought to be read, in the general sense which I am indicating to you, the only question is whether any honest man could entertain such an opinion upon the facts which have been proved before you in this court. If that is the question, I submit to you that there can be but one answer to it, because you had here multiplied instance after instance of men occupying the highest positions in their respective walks of life who have come into this court and told you upon their oath that they think it a fraud, that they call it a fraud; and if one honest man may hold that opinion, why may not another honest man hold it? Let me call attention to what I mean in that connexion. There is Dr. Waldo, a man who occupies a very responsible position in this great City, a man who has come before you and whom you have seen and heard. He tells you that at the time he spoke of this thing as a fraud and applied the word to the course of dealing. He has come here and tells you that he still thinks so, and he comes here and tells you: "In my judgment, all THE LANCET did was to reproduce what I had said and to say that in their judgment they considered I was right." There is Mr. Tilley—and upon this I must ask you to bear in mind that these various witnesses whom I put into the box I could not ask straight out whether, in their judgment, they considered this system a fraud, because that would not have been admissible; we could only get their opinion if my learned friend chose to cross-examine them about it, and he refrained from cross-examining all of them in this particular point, but all those whom he did cross-examine upon this particular point gave the same answer, with the exception possible of Dr. Willcox. Mr. Tilley said: "I consider it a fraud"; and he gave the reasons why he considered it a fraud. One man may consider it a fraud for one reason, and another incident in this history may appeal to another man who will call it a fraud for another reason. It does not matter what the reason is, the question is whether you think that any honest man could come to this conclusion upon the evidence. There is Mr. Francie, a man who has had great experience in the treatment of asthma, and who has seen many cases who have suffered according to his view from Mr. Tucker's treatment. He says so, and Mr. Pepper, a very eminent man, ordinarily known as Professor Pepper, has come and told you the same thing; so you have here gentlemen who have come before you and upon their oath have said, "I have held that opinion, and I hold it now; I am an honest man, and I am entitled to express, if I am asked, what my opinion is." So much for that.

Now let me deal with the evidence which has been given on the one side and the other. I have indicated to you what the plaintiff's case is, and I will deal quite shortly with the points. It is necessary that I should get to close quarters with his evidence in order to ask you to look at it in the light in which I submit it ought to be looked at. First of all he says, "I want you to consider this fortnight's trial of mine before you come to any opinion as to the view which a man may express about my treatment." I have said a word about that, but I desire to refer to it again, because I suggest to you that the inference, if inference there be, to be drawn from that fortnight's trial is against the plaintiff rather than in his favour, and I will tell you why. He deals in this liquid which contains these powerful poisons. We know how potent they are and how powerful they are, and we know that if anybody suffers from asthma or kindred complaints a dose from this atomiser will give them relief. We know that; whether it will do them ultimate harm or not is another matter; whether their disease is one which is appropriate to that stuff at all is a matter with which I will deal in a moment, but we know that they will get relief. What is the plaintiff giving away when he sends the stuff which he knows will give relief to a person suffering from such a distressing complaint as asthma? The fact that they get relief will be the greatest possible inducement to them to take it, and therefore he sends this thing out, knowing practically that every person who can use the atomiser at all will buy it. Some of them may send it back, because they cannot get the thing to work, but everybody who can get it to work he knows quite well will keep it. If that is so, ought he to take credit to himself for the fact that he allows them a fortnight's trial? It is a most material point in his way of dealing, because you will see that if you give a man a fortnight's trial, and he takes it, he is for ever debarred from making any complaint about it. When the plaintiff says, "I have had 25,000 people and none have complained," what use is there in complaining to a man who has given you a fortnight's trial of a thing? You do not complain, and you do not complain because he has given you this opportunity which he knows you will take; and, further, about these complaints let me say this: one of the strongest objections which we have to this liquid is the fact that people will use it too much with disastrous results to themselves. Do you think that those people who are suffering in that way will complain? It is not that they do not like it enough, the mischief is that they like it too much; and do you get complaints as to this system of his, and is not this liquid in which he deals one in which he shuts the door to complaints by the system which he adopts, and cleverly adopts? Gentlemen I suggest to you that so far from this being a point in his favour the fact is that by this trial he gives people nothing and leads them to believe that they are getting a great deal.

I have dealt with the complaints, I have dealt with the fortnight's trial, and it only remains to deal with the patients that he has called. You will remember what our case is about those. Our case is not that it will not do people good; our case is that there are certain classes of people to whom it will not do good; our case is that there are a great many people to whom it will do harm. We say that it will do harm to persons suffering from heart disease;

see the vapour issue from your mouth you will know that the vapour has entered your lungs. *Therefore your risk* of cocaine is the risk of a quantity of vapour large enough to fill the lungs which is medicated to the extent of *3/20000th* parts of a grain in, I suppose, two quarts of it—a volume sufficient to fill the lungs. Doctors come here one after the other and tell you, "We call that poisoning people; we say that the use of that remedy is the use of a poison, because we say there is that trace of cocaine in it." I venture to say to you that whatever the *doctors* say about it, the common-sense of the matter is that there is nothing poisonous at all in it, and that the reason why nobody is produced here who has been either poisoned or hurt is, because nobody ever has been poisoned or hurt, and that it would be as reasonable to speak of the man who had got his dose of this vapour into his lungs as having undergone poisoning as it would have been for Sir Lauder Brunton to tell me when I got back *from my* lunch that because I had taken a little whisky-and-soda with my lunch I had been poisoned. It is the abuse of a thing which you refer to when you speak of poisoning in such a connexion. Sir Lauder Brunton compared it to the case of a man who used a stimulant, as we call it, habitually. He says that is a poison. Of course, if that is the kind of thing which you are dealing in, very well; if it is a temperance platform you are speaking from so that when you hear the orator you know that what he has got in his mind is a notion which leads people to speak of good creatures of the earth as though they were foul things, without discrimination, as though they were necessarily evil, whereas they are only capable of evil. If you have got that explanation then we know that when a man talks of poisoning he is talking in what we used to call a Pickwickian sense about poisoning; but when you say that a man who sells a specific medicine is poisoning and robbing people and that he is carrying on a system of fraud you are not talking in a *Pickwickian* sense, but you are talking language in the sense in which it is understood, and whether it is true or not you mean people to understand, and THE LANCET meant people to understand, that Mr. Tucker was dishonestly selling poisons, and that he was robbing and injuring people by a sale of poisons, and fraudulently doing it. I venture to say that after you had heard what Sir Lauder Brunton had to tell you about his justification when he compared this inhalation of the vapour of cocaine with the habit people have in this country of taking alcoholic liquors, and said it was the same thing—*I venture to say* he had given away the case for the defendants, and that it was idle to pretend that there was any real danger against which these doctors had come here to warn you. There is nicotine in tobacco; very well. If you take pure nicotine you will be poisoned, so if I give you a cigarette, gentlemen, I am poisoning you. There is caffeine—a very powerful drug—in coffee. If you take it neat it will kill you, perhaps; *if you give me coffee you* have poisoned me. There is cocaine, it is said, in some infinitesimal quantity in this vapour. You are a free man and you can go about your work, but the man who has provided *that relief* is fraudulent and dishonest and a rascal, and he has poisoned you. I ask you to attach no more importance than it deserves to that body of medical evidence. It was an attempt, I venture *to say, to* raise a bogey in the public mind against any specific medicine which is not prescribed by medical men. It is not the first time it has happened and it probably will not be the last. Medical men naturally enough take an *extravagant* and unreasonable view about these things. I ask you to assume that they took that extravagant and unreasonable view because they were medical men and not because they were *expert witnesses*, and I ask *you to take* a reasonable and sensible view and to say whether it is an abuse of language if a man knows all the facts to say that Mr. Tucker was a man who was poisoning his fellow-men, which is what they say with regard to him.

I have come pretty well to the end of what I have to say to you, because you have listened *to* this case and I am not going to make you a long oration. They say cocaine can only be sold under the restrictions of the Pharmacy Act. If their evidence is true these medical men have known for years that there was cocaine in this specific. How is it, if it was true, that Mr. Tucker has not been stopped by means of the Pharmacy Act? The Pharmacy Act is quite simple in its operation: it says that you shall not sell poisons. There are decisions on the Pharmacy Act, and one of them is to the effect that if the trace of poison is infinitesimal, if you cannot fairly say that the mixture is a poison, then the man is not guilty of an offence. That may have something to do with it, but when they brandish the Pharmacy Act before you my answer to that is, "You know all about the Pharmacy Act and you evidently know all about Mr. Tucker. If it applied to his case and you are so anxious to stop him why did not you stop him?" Nothing of the sort. The *Pharmacy Act* had nothing to do with it; they did not even consider it; but it came in as an after-thought. Then what else is it that is said? Cushing is spoken of; I must not omit that. *It is said*: "You sold this to Cushing for £3." Cushing was an intelligent fitter, a mechanic, who in 1904 found himself troubled with asthma, and said so, and who from 1904 to the end of 1906, apparently carried this inhaler with him, and relieved his asthma; and Cushing *by that means was able to go on* and earn his and his wife's livelihood down to the time when he died of a different disease with which he was also troubled—namely, consumption. *As was shown* by the evidence, this intelligent man, knowing of his occasional trouble, and knowing, no doubt, of the deep-seated trouble which must kill him eventually, and having no faith in anything the doctors could do for him, but knowing the effect of this remedy, having tried it, he bought it, and, having bought it, he went on using it; and the last supply to him had been within a very short period of the time when he was *no longer able* to use any remedy. *Then it is suggested*, forsooth, that that was a fraud upon Cushing. They have not even ventured to call his wife. His wife was at the inquest, as they knew, and you would have thought if there was any fraud on Cushing that Mrs. Cushing would have known something about it. The report of the inquest said, of course, that she was in court. The fact is that Cushing was a man who had derived benefit, who had *saved himself from the possibility of asthma*, and from doctors' bills for asthma, for two or three years before the time of his death, by the use of this remedy. That is the true position about Cushing. Never a word of complaint has ever been made from first to last, but a resort to the one means of relief which was found to be open to him. No wonder that they did not, in their defence in this action, venture to suggest that Cushing was defrauded; and they did not; not a word has ever been said to that effect. It is reserved for my friend's innuendo in a question and his suggestion to you in his speech. That was the case of Cushing. In addition to that it was said, "You say this thing is harmless"—the very same thing which the medical profession through Messrs. Oppenheimer say with regard to the imitation—"*If you inhale* this it is quite harmless," which is the same thing as Dr. Tucker said in the latest circular which he sent out. He has been attacked as to the constituents and he says, "*Well, however* that may be, the use of this vapour cannot be otherwise than harmless, and it is found highly beneficial." It is said, "You said it will cure asthma." The specific attack undoubtedly is cured. The testimonials here are the best means of showing what they said. I have read to you three or four of them, and every one of them said: "We do not say it has cured asthma; we say it effectually relieves it and *it is very much better.*" *Then it is said*: "It is an extravagant price." There are some of the witnesses here who have had experience of the prices.

When this *defendant* wrote his charge of fraud against Mr. Tucker he was not thinking of the extravagance of the price, he was not thinking of the question of whether there was more or less of a trace of cocaine, he was not thinking of whether it was immediately beneficial or permanently beneficial, he was *not* thinking of poor Cushing; he was thinking of what he regarded as the interests of the great medical profession. He desired, and he permitted himself, to bracket Mr. Tucker with a class of people who he said were robbers and murderers, and now he comes and he has to justify himself. You have heard all his evidence; you have heard the devices which have been resorted to in the vain attempt to convert these matters of disputed opinion, of disputed fact even, into a justification of a charge *of fraud*. I venture to say to you that that charge is proved to be untrue, and it is proved equally to be grossly unfair; and I venture to say, further, that having come into a position in which it was open for them to have shown courage and honesty in dealing with this man whom they had libelled, the defendants, after they have become aware for many days got back to her work. I do not think she mentioned what it was. It is quite plain that she is not suffering from any disease which would make it dangerous to use the stuff. There is no indication that she used it too much. She is one of the people who benefited I do not doubt, and I have always tried to make it plain that you may have a thing, and you may deal in a thing, which may do good to some people and which yet may be characterised as fraudulent if you are sending it out indiscriminately, and you are certain, or reasonably certain, that it will do harm to others. The doctors I want to speak about in a different category. I should have thought the very last person to whom my friend would have referred to as being an instance in his favour was a doctor, and for this reason, that a doctor is aware of the dangers. A doctor is a person who is in the position of somebody who is warned, because he does not require warning, and he knows the danger; therefore, if you sell a thing to a doctor who knows of the danger of using or abusing this vaporiser, you are selling it to a person on exactly the same conditions as if you told him all about it. These doctors, of course, stand in a different category. Dr. Clark was a strong witness in the plaintiff's favour, but he is a man who, I suggest to you, holds very curious views because he went so far as to say that he would recommend this to his patients, and apparently without any warning, although he knew of 20 cases in which he knew it had given people the cocaine habit. There is no accounting for differences of opinion, but to hear a medical man go in the box and say that——

Mr. Justice RIDLEY: Although he was told of such things he did not know of them.

Mr. ELDON BANKES: If he were told of such things, yes. Supposing he were convinced that 20 people had acquired the cocaine habit from the use of this thing he would still recommend it.

Mr. Justice RIDLEY: He said it would never do anybody any harm at all and he would not believe it.

Mr. ELDON BANKES: That is quite true, but what I am saying is quite right, I submit, and it is this: You must judge what kind of a man this is by his answers. He says: "I do not believe it will do any harm. I have never known it to do any harm, but even if I was satisfied that 20 people had acquired the cocaine habit from using it I should still advise my patients to take it." The next witness, Dr. Rawlings, takes a very different view. I want to remind you of his evidence, although, perhaps, I am taking too long as it is; but you will remember he said he considered cocaine a very dangerous thing. He said it ought only to be used under the most careful restrictions and under medical supervision, and so on. There is a man who took an entirely different view; he had recommended it to a patient, it is true, but he could not tell you what the effect had been upon the patient. Of course, he had not sent for it, but that is a case in which it was recommended under medical supervision, and that is an entirely different case from the case with which I am dealing, and the dangers which I am trying to point out to you. The last witness I deal with separately because he is the one man of all those who have been before us who apparently used it, at any rate to the extent of an ounce in three months. There may be people, of course, to whom the use even to that extent is not harmful, but he did make use of a plaintive expression, it seemed to me. He said "unfortunately," and you will remember the tone in which he said it. Then he was asked which he meant by that and he said that had reference to the price. Whether he used it once in three months or once in a year would only make a difference of about 32s. a year, and whether he really used that expression of "unfortunately" almost with a sigh, a gasp, because it was really a question of price, is a matter for you to consider. However, that is the plaintiff's evidence. Now I have dealt with it, and I submit to you that, looking at it fairly and looking at it reasonably, as I am sure you will, and bearing in mind the words which you have to try, it does not really assist you to call a number of witnesses who have been benefited, unless they come into the class of people whom I have been indicating who would be injured, it does no good. Now let me pass to our evidence, and I will deal with that as shortly as I can, and I am sure you will not grudge me the time.

Mr. Justice RIDLEY: It is half-past twelve, Mr. Bankes.

Mr. ELDON BANKES: I hope I have not been unduly long, but I must deal with this evidence, gentlemen, shortly, after the view that has been indicated to me more than once as to my position in this matter. I must deal with our case. We say this first of all; we say that this liquid does contain these poisons. You know it, and I need not go into it again; it does. We say that those are being sold in flagrant violation of the law of the land; and the importance of that is this: it is for the plaintiff, of course, to say whether he will take upon himself the risk of doing what the law forbids; that is one thing; but from my point of view the importance is that that law would not have been passed unless it had been recognised that the restrictions which the law imposes are necessary for the public safety. What are those restrictions? The restrictions in the case of atropine—and this contains atropine—it so happens are stronger than the restrictions in the case of cocaine. In the case of preparations of atropine (which this is) the law says that you may not sell it except to a person you know, or who is introduced by a person whom you know, and the law says that nobody may sell it except a registered chemist. If that is the law for the Englishman why should it not be the law for the gentleman who has been an usher in a school in America and comes over here and sells these things over here in enormous quantities? Why may you not form a strong opinion about a man who comes over here and disregards—I do not care anything about the law—but disregards the precautions which the legislature of this country, which means our representatives—your representatives and my representatives—have passed into law in Parliament because they recognise that in this country, at any rate, those are necessary precautions for the safety and well-being of the community? Nobody may sell a preparation of atropine unless he is a chemist, unless he has gone through the course of training which the law prescribes before a man shall be put into that responsible position; he may not sell it except to a man he knows or to a man introduced by a man he knows; he may not sell it unless he keeps a poisons book and enters every name, and so on. I need not go through the precautions but the fact that this man disregards those precautions which are reasonable and proper precautions is one ground, I submit, why a writer may use language of the strongest possible character.

The next point is, we say that it is sold under conditions in which the sale is likely to do serious harm. Why do we say that? May I put it shortly? We say it because he advertises it as a cure for asthma. Asthma to the patient presents the same symptoms as all those other disorders which I have enumerated, and therefore if a patient writes to him because he thinks he has got asthma he may be suffering from heart disease or consumption, as that man Cushing was, and he will get a thing for which he has to pay a large sum of money which will be positively harmful. It would not be fair to you that I should go through the evidence of medical gentlemen whom I have called, but I do ask you to remember who they are. They are the heads of their professions. I have called, amongst others, the man who, I suppose, at this moment is the actual head of the British medical profession, Sir Richard Douglas Powell, who occupies at this moment the position of the President of the College of Physicians. They one and all have told you that in their opinion this sale in this way is calculated to do harm. They ridicule the opinion that because it is given in such infinitesimal doses it will not do harm and some of them rest their opinion, not upon the knowledge of the effects of these poisons, but upon their actual experience of cases which have been brought before them. There is Sir Richard Douglas Powell; there is Mr. Francis; there is Mr. Tilley, all of them speaking from an actual experience of what they have actually seen. I need not go in detail into the reasons they gave, but I should like just to refer to one reason to remind you of it. You will remember the emphatic language used by Sir Richard Douglas Powell when he said that one of the great dangers of this thing is that asthma is a most distressing complaint, and if a patient finds anything that relieves it, to use his expression, they fly to the remedy and take too much. I submit to you that no evidence could be more cogent, and it ought to be convincing. Why are you not to accept it? Can you possibly disregard it? What answer is it to say that there may be many hundreds of people who have not suffered harm if you find this evidence that there must be people who do suffer harm and that there are people who have suffered harm? Gentlemen, remember, please, that you are considering that evidence in reference to a course of dealing in which this stuff is sent out without any sort of inquiry as cease." There is no doubt that the quack advertisements which appear in other newspapers are alluded to, and it states that the object desired to be arrived at of passing the medicines on to the public could not be arrived at without the assistance of such newspapers. There can be no doubt about that; but is it correct to say that there has been no attack upon the character of the plaintiff? Mr. Bankes says I think this: The man's character is only involved in his system of dealing; that is to say, if I have to attack the system of dealing I must attack his character. If you do attack his character he is entitled to his remedy, and you must meet him in that way which Mr. Bankes characterised as a brave one—come forward and say it is true. In this case is it not almost enough to find that Dr. Tucker's particular asthma specific, and the inquest which was held upon Cushing in which it was mentioned by the coroner as a fraudulent scheme—that that was the foundation of the article, to show that it was an attack upon Dr. Tucker? Would anyone in reading this article exclude him from the denunciation or not? "Dr. Tucker's asthma specific inhaler" is mentioned as the beginning; it is made, as it would appear to me (but it is for you to say whether that is correct or not), the foundation for the observations which are made with regard to the general scheme of publishing these advertisements and passing poisonous medicines off upon the public. If it is made the foundation for those observations is it not the necessary consequence to the mind of anyone reading this article that Dr. Tucker's asthma specific inhaler is precisely one of those things which is so foisted upon the public? If it is, then does not the word "fraud" which is passed as the right word for this kind of dealing apply to Dr. Tucker? That is the sort of argument which has presented itself, I will admit, to my mind. I will read it again: "He had been using Dr. Tucker's asthma specific inhaler. Dr. F. J. Waldo rightly stigmatised this sort of dealing as a fraud." What sort of dealing? Why Dr. Tucker's asthma specific inhaler. Would not the mind of a person reading this refer it to Dr. Tucker? You go on and you find this about those newspaper advertisements and then you come to this: "The remedy is in the hands of the public, who have only to signify their displeasure at reading in their journals invitations to be robbed and poisoned." It is argued that robbing and poisoning have nothing to do with Dr. Tucker. Not so directly perhaps, yet those observations read by an attentive mind appear to me clearly to indicate (though it is for you to say whether they do or not) that Dr. Tucker was one of those people who by such a system passes his wares off upon the public. I pause for a moment because I ought to remember that Dr. Tucker is not Mr. Tucker the plaintiff; but, gentlemen, do you think that will do? Mr. Tucker is so associated right through with this matter as the agent for his brother who is the inventor of this specific that it appears to me hardly possible at this stage of the case that we should distinguish between the two. If you charge Dr. Tucker's inhaler as being a fraud is it not Mr. Tucker who in this country circulates it. I do not think it is possible to pause very long upon such an argument as that. It would appear to me that if you think it is an attack upon the character of the man who made this medicine, who invented this specific, you will think that this is also an attack upon the character of the man who disseminated it. What is said to the contrary? I think I have put the point that Mr. Bankes urged upon you as plainly as I can. It may be that you do not think that those observations which certainly do occur to my mind are properly made, and that the writer of those advertisements was merely alluding to a system and casually mentioned Dr. Tucker's name; I do not know, however, what force you will attach to that. I think it is true that he had another object in this matter, and I think it is fair to remember that he does mention the advertisements which occur in other papers; but I wish to say this, that if in the course of his observations upon that subject, be it his chief object or be it not, he found it necessary to make a charge against the plaintiff's character he cannot shelter himself here under a plea of public interest, but he must justify it and say that it is true. That is what I have to say upon the first point; do you find that this is an attack upon the character of the plaintiff so far as the observations may arise upon the libel itself.

Now I want to call your attention, which I must do upon this point, to what was said by the witnesses who were called for the defendant—most valuable witnesses among the leaders of the medical profession. I should not like to be found saying a word against them, and I have no wish to do any such thing. They gave some evidence of great value which I think is completely incontrovertible. I do not wish to suggest to you that you should controvert it any more than I do, but it was not a necessary part of their evidence to use the word "fraud" at all; it is quite out of the way, and some of them did not use it. Let me see how each of them did use it, in order to ascertain in what way they treat this word which I take as the key of the situation merely for shortness, meaning to express thereby an attack on the plaintiff's character. Dr. Willcox, an eminent gentleman, gave valuable evidence about cocaine and atropine, and the undesirability of selling it in a bottle without "poison" upon it, and without the supervision of doctors, with all of which I for one find myself in agreement. He says upon the question of fraud: "I could not say that you were guilty of fraud for doing it because it would be unjust." What does that mean?

Mr. ELDON BANKES: May I interrupt your lordship? That was his answer to my friend's question: "Should you say that I was guilty of fraud if I recommended it to a friend believing it to be all right?"

Mr. Justice RIDLEY: Yes; that is the very thing which was done as it appears to me: "I could not say that you were guilty of fraud for recommending it, for it would be unjust." Therefore fraud in his sense as he used it means to say that it was a dishonest thing to do. If so, where is the argument for the defendant that the word "fraud" used in this article does not apply in a dishonest sense to the plaintiff, but is merely a general reference to a system, and is used to indicate not any dishonesty but a statement calculated to deceive: "I do not think it is fraudulent to sell the article, but the man ought to be qualified before he deals with it." There again, does that show that the defendant's reading of the article is right? I should certainly have hesitated to say so. I think Dr. Tilley, the next witness, used this expression, "I think it is fraud, because he did not cure his patients when he said that it would," and then he quoted the different sentences in the instructions from which in his opinion it followed that there was a statement that it would cure; so Dr. Tilley thought it was fraud in him, because he did not cure his patients when he said it would. That also seems to me to show that in his opinion this word "fraud" in this article was pointed at the man who did it and not at the thing itself. Dr. Waldo we know. He says, "I thought it was a fraud, not because of the Government stamp, a matter which I think I may leave out of the question, but because he said that it was a cure," taking the same view as Dr. Tilley. "If a medical man said it was a specific for asthma I should still say it was a fraud in his case, because it is incurable." So that there you see it is a personal matter which the fraud indicates and not a system. Sir Douglas Powell did not say a single word about this point. Though his evidence was extremely valuable upon the general point he said nothing so far as I know about this. Sir Lauder Brunton in a similar way I think was silent about the point which I am now dealing with.

Mr. ELDON BANKES: They were not asked, if your lordship remembers.

Mr. Justice RIDLEY: They were not asked; that was the reason. That is quite sufficient. I did not suggest there was any other reason, or that any question was put about it which they did not answer. Mr. Francis said, "I never thought of fraud in this matter one way or the other," so he does not assist us very much. Mr. Pepper says, "I came here in the belief that it was a fraud. However innocent in his intention I should say it was a fraud from his statement of the operations. It is a mis-statement to use the word 'heal'"; and he took the line that because the word "heal"—I only take it as one instance—was used when as he said there was no laceration of the membrane, that was a mis-statement which would make it a fraud. That is a view which I do not think is concurred in by anyone of the several witnesses who have been called, and I give it to you for what it is worth. Dr. Cushny, the last witness to whom I need allude in this matter, said that its administration was not fraudulent. You do not get very much light by these statements, and I do not suggest that you do, but still they are there, and it is necessary to mention them to you. I think that upon this point it is the article itself which ought to guide you, and having read that, also what your opinion is as to the difference which is suggested and say is this upon this word "fraud." You will remember that the plaintiff said that he is selling this stuff indiscriminately, and indeed without apparently caring what the constituents are. It is quite legitimate to say of his system of dealing that it is a fraud upon the public without imputing any moral blame to him, if the fact be that he honestly believes that the stuff is genuine; but if a man puts himself in this position that he undertakes the sale of a thing without knowing what its contents are, he cannot shelter himself, if it is properly said of his system of trading that it is a fraud upon the public, behind the fact that he has thought that ignorance is bliss, and that it is folly to be wise, and he has not taken the trouble, for some reason best known to himself, tp endeavour to ascertain what the contents are. He takes upon himself the responsibility of disseminating this stuff wholesale, and if he takes the responsibility, so he must take the blame if the fact be that the system is one which deserves the severest censure.

I am much obliged to you. I hope I have not taken too long, but you will realise that there is an important question involved in this case, as I said before, beyond the mere interests of the plaintiff and defendants; and I respectfully ask you to say that now that this thing has been thrashed out it is proved, and proved beyond any question, that this system of trading is one which admits of severe condemnation, and that the condemnation which has been passed upon it is not beyond what the occasion permitted.

Mr. DUKE: May it please your lordship, gentlemen of the jury. The attack which THE LANCET newspaper, that is the defendant in this action, made now nine months ago upon Mr. Tucker has been very grossly aggravated by what has taken place in the course of this trial. The attack which was made in THE LANCET was an attack made confessedly without any knowledge of either Dr. Tucker or of his specific. Up to this morning one hardly conceived it possible that where a defendant in an action of this sort was going to ask the jury to say that whether the words he used were strong or not at any rate they were fairly and honestly used—one hardly thought it possible where that was going to be one of the defences relied upon, that the defendant should close his case and not put into the box before the jury which was to try the case the man who had written the libel in order that the jury might see whether that man had taken any sort of pains whatever or gained any information whatever before he launched against a man who was carrying on a large business in this country a charge of fraud which if it were true and if it were found to be true must not only destroy his business but destroy his character.

This defendant, the proprietor of THE LANCET, coming here with that responsibility upon him, that he has chosen to make such an attack as he has here upon another man's business and another man's character, treats your intelligence with such contempt that he does not go there to say that he believed a word of this and if he did not write it himself he does not call his servant who did write it before you to say that he believed it or thought there was the least justification about it. That is a very remarkable state of things. Instead of that he relies upon an array of expert witnesses who have been occupying your time now for nearly three days, gentlemen, a part of whose business it is to go into the witness-box and to give evidence to tell you that cocaine under certain circumstances is a dangerous poison. That is what he has done, and for the rest of it, for any other inducement which could be utilised to cause a jury to give their sanction to a charge of fraud against a man who is said by his customers, and by every customer of his who can be found, to have carried on a business which conferred upon them the highest benefits and earned their gratitude so that they were glad to come here and testify on his behalf, but has in order, as my learned friend says, to brand that man as a fraud, to brand his business as a fraudulent business, to brand his remedy as a fraudulent remedy, there are an array of expert witnesses and my learned friend Mr. Bankes. That is why, feeling that the labouring oar was left with him this morning and that the expert witnesses did not seem to have come to much, my learned friend has had to spend the whole of this morning in the elaborate effort which he has made here before you to induce you to say that an honest transaction was dishonest, an honest business was a dishonest business, and that an honest man was a dishonest man, because that is what you are asked to do.

There has been a good deal of trifling with the charge that is made here, but we have had it out this morning, because point by point has been sought to be made and directed against Mr. Tucker to induce you to say that he was personally dishonest, and to think so—to come to that conclusion; so that we know now what they meant and what the language of this libel meant. The words of it, I am sure, must be fresh in your recollection. Having got an opportunity furnished by some wild observations—wild and unwarranted observations—of Dr. Waldo, observations as injudicial as any observations made by an officer holding a judicial position possibly could be—having got the opportunity of those, and having had them sent to him by Dr. Waldo for the purpose, the defendant without inquiry and without knowing anything about Dr. Tucker, without analysis of the remedy or anything of that sort, writes this article and he stigmatises Mr. Tucker's system of dealing as a fraud, and he goes on to say in effect that there are in this country a number of persons who sell fraudulent specifics, that Mr. Tucker is one of them, and that these frauds amount to robbery and to murder—frauds which he says Mr. Tucker commits; and then he says, "Why do the newspapers of this country help Mr. Tucker and these other people, these fraudulent people, to commit their frauds?" That is the effect of what he says. When you come to see what warrant he had for saying it, by an answer on oath which is made here this morning on the part of the defendant, the warrant is: "I made no inquiry as to the truth of the statement set out in the said interrogatory before printing and publishing the said statements and took no steps to test the reliability of the information which I had previously received as to the said statements because such information was derived from a cutting from the *Morning Advertiser* of Wednesday, Jan. 2nd, 1907, which said cutting was forwarded to THE LANCET by Dr. F. J. Waldo the coroner" and certain advertisements of quack medicines. Having said that originally he corrects it months afterwards and says, "I also had your directions for treatment." Having made that attack upon a man's business integrity and personal integrity he now has to justify it or to excuse it and you have seen the sort of means by which it is proposed to be done. There are two answers, so it is said—I believe there is only one, but my lord will tell you—to an action which is brought against you if you have charged a man with fraud. I anticipate my lord will tell you, if my lord takes my view of the law, that if you charge a man with fraud, if you say a man is a fraudulent man and you do not prove it, you must pay for it.

Mr. Justice RIDLEY: Yes; that is right.

Mr. DUKE: I so understand.

Mr. Justice RIDLEY: I have not any doubt about it at all.

Mr. DUKE: It has been established a very long time. It has been said that public writers have the privilege of doing this sort of thing. A man who is invested with judicial functions may do injustice to his fellowmen and not pay for it——

Mr. Justice RIDLEY: It would never do at all. You cannot justify an attack vilifying a man's character by saying that it was fair criticism upon a matter of public interest. Where would the character of individuals be? I shall lay that down very strongly to the jury without any hesitation at all. There are authorities without end upon the subject. The question for the jury is, Is this an attack upon the plaintiff's character? If it is, he is entitled to a verdict, but if it is not, and is a mere criticism upon a matter of public interest, therefore not attacking his character, then the defendant would be entitled to a verdict.

Mr. DUKE: If your lordship pleases.

Mr. HUGH FRASER: I do not know whether I ought to ask your lordship to hear me on the point of law.

Mr. Justice RIDLEY: I have heard Mr. Bankes and I shall not hear any more.

Mr. HUGH FRASER: I know he cited the authorities in the course of his speech.

Mr. Justice RIDLEY: He cited the authorities but he has not cited the leading one. I have no doubt he knew about it. I have no doubt about the law, but if there is anything wrong about it you must take it elsewhere. You cannot justify an attack upon a man's character which charges him with robbery and fraud—an attack of an offensive character—by saying that it is a fair criticism upon a matter of public interest.

Mr. DUKE: That is what I understand to be the law. I did not bring a lot of books here, gentlemen, and read you passages out of them because, of course, before you would be able to gain enlightenment from them you would have to have some knowledge as lawyers, and you would have to further from these testimonials, but I think *you will find*, if you take trouble to read them, that some of these people were not working men indeed, but those who bought this specific have been very glad *to get it* for the money and some witnesses called before you said so. What is it? It is not that you have sold it and that you have to pay for it; you have to *pay for it if you like it*, but if you do not like it you can send it back again. It is not possible to say that £3 is the price of the inhaler. It is not. It is the price of the inhaler and the two ounces with the knowledge that it will do you good.

The Jury: Four ounces.

Mr. Justice Ridley: That makes a great deal of difference. That is not the price of the thing itself, for I do not see how it can be shut out of the case after the argument that has been put before you about this, that you do not pay at all and you could not be asked to pay unless you signed this: "At the expiration of the two weeks' trial I agree to pay for the treatment or I return the atomiser and what fluid there may be left, by mail, charges prepaid"; that is to say, if it does not suit me I send it back; no cure, no pay. You do not get that out of many doctors. I do not mean to say that it would be right for the medical profession. I do not say it would, and I do not for a moment think they ought to come and say: "You need not pay me unless my medicines cure you"; but it is not a fraudulent thing to say to a person. It is not robbery and it is not poisoning. It may be objectionable, but why *not*? What is there that is wrong in itself? When a man is not a member of the medical profession, he is subject to certain laws which he *must observe—I mean the Pharmacy Acts*; and if he does not, he may be prosecuted for not observing them. He could not be prosecuted for that, and why is that to be wrong, and why is that to be called robbery or fraud? Surely it is nothing of the sort. You may think it is wrong, and you may think, as I do, that it would not be the right thing for a medical man to do; but are you to charge him in words of this serious import with having done that which is improper because he has done it? Surely not. Then I say what is the next?—that you said it was a *cure when it is not*. Gentlemen, I think it is scarcely possible to lay down this that he did say it was a cure, without making a long explanation about it. He said that it cured the spasms, and he said it prevented them from recurring. He said it modified them when they did recur; but he also said that he could not cure it as an absolute cure so as to prevent the possibility of its recurrence. That is the long and the short of it. He says in the witness-box that he does not cure the liability to asthma. He said in the pamphlet, and in the instructions, after considerable explanation as to how it worked, and the way in which it modified the spasms, and rendered it less likely that they would recur, that it was a cure; he did say so. Here are the words, and they are in several places, I think. At the head of the pamphlet which I have been reading to you there are words of that kind if I am not mistaken: "A physician cured of asthma and hay fever after 20 years of suffering"—that is Dr. Tucker himself, the brother—"and experimenting on his own chronic case." That is called a cure; but then it is subject to the observations which appear in the subsequent introduction in the pamphlet which show the way in which it will work. It is for you to say whether he did say in so many words that this is a *cure or* whether he did not. In the instructions in a similar way there is this; after several sentences about how you are to use this atomiser comes this: "You will notice by *the above instructions that* it is necessary for the vapour to reach the lungs in order to arrest the attacks, heal the mucous surfaces, and cure the disease." That is the statement which is relied upon by one of the witnesses, I think Mr. Pepper, but I am not quite sure—the word "heal." He says: "That will not do. That is a statement which is a fraud. There is no healing because there is no wound." But think; there is no wound, but suppose it is inflamed, suppose it is in that condition that it gives rise to the asthmatic attacks at once, and you induce a quieter condition in the membrane so that it does not do so any longer, is not that healing? I should have thought you could have used the word heal not merely with the meaning of healing a wound which has been made in your flesh, but as meaning the surface which has not been broken, or as healing you from a disease which never had any wound in it at all. I should have thought it was a general expression. Perhaps not; that again will be for you. Those are the two chief attacks which have been delivered in this matter. Of course, there is the third one—namely, that it was not a thing which was to be used without the supervision and the management of the medical profession. With that I think I have sufficiently dealt. Having regard to that on the one side and to the certain good which it has produced to the witnesses called before you on the other, do you think that this criticism on a matter of public interest, which undoubtedly it was, was a fair criticism or not? Did it make the right allowance for the good that has been done whilst it attacks the other? That is what I *think a fair criticism* ought to be. I do not say you are to measure criticism with accurate care and detail, regarding each word, but in doing this did they *make allowance for* what the man has done of a good sort, whilst they attacked that which he was doing which was of a bad sort and which might result in the *extension of* what is known, as we now understand, as the cocaine habit? Gentlemen, it seems to me, although I have been longer than I meant, that I have at all events covered the ground now. You will, first of all, be good enough to say, having regard to all those matters, do you think that this was an attack on the character of the plaintiff, and if you think that it was an attack on the character of the plaintiff he will be entitled to a verdict in my judgment, although you should think that the other part of the case showed a fair criticism on a matter of public interest because the defendant has attacked the plaintiff's character, and has not justified that attack. But it may be that there may be other opinions upon this matter, and I think it is desirable that you should answer the second question which I have been discussing before you. Was it fair criticism at all on a matter of public interest? I do not say, nor do I think you can, that it was a matter of public interest, but were the comments fair?

If you find for the plaintiff what are the damages to be? That is all that remains. It is true, I think, that he has not suffered in a pecuniary sense; but, gentlemen, this is an important matter to him. I do not think that it is of the importance which Mr. Bankes thinks for the defendant, for I do not take the same view. I do not think the principle is at stake for which he contends. The principle which is at stake is this: Can a man's character be attacked with impunity? That is a much more important matter. If it can, then the defendant is in a better position here than I have taken it any defendant could be in this country. The question here is what damages you award if this man's character has been attacked as being guilty of fraud, robbery, and poisoning, which, as I understand it, is meant in being a quack. With regard to the word "quack," it is used in various senses. It generally means in its harmless sense a man who is not a qualified medical practitioner, but it may also be meant in the harmful sense, a man who pretends to a skill which he *does not* possess—a charlatan. I do not know which it is meant for here, but I should think in the more harmless sense. A quack may be simply a man who *is* not a *medical man*; but then what would other people understand it as meaning? Most people, I take it, would take it as meaning that this man pretends to cure, and he pretends *to* have a *specific* when he has not got one at all. What do you say to that? Then there is this, that he is one of those who carry out a system of robbing and poisoning upon an *uninstructed and* credulous public. I think, although juries must be moderate in all the verdicts which they give in cases of this kind, this is a case in which, whilst you are moderate you ought, if you find in favour of the plaintiff, to give him some substantial sum to show that in your opinion, although it may be correct to say, and is correct to say, that these drugs which have a poisonous character ought to be under the Pharmacy Acts, and that they are not to be administered without the direction of doctors, yet those who have found out a *specific* which is of value, containing though it does some portion which is poisonous, and which has largely benefited the public, whom they can call before a jury, are entitled to have a *sum* which shows that in the opinion of the jury they have not been guilty of fraud, robbing, or poisoning. I do not say anything more about the case but leave it simply in your hands to answer those questions: "Was it an attack on the character of the plaintiff? Was it fair criticism on a matter of public interest? What are the damages?" If you wish to take with you either the pamphlet or the instructions or any of the papers they shall be put into your hands to deliberate upon in your room.

ects ; and we warn people against using Tucker's remedy." ey could have said that. They could *have said*: "We lieve this cannot be sold, except by a member of the armaceutical Society, and Dr. Tucker ought not to sell ." They could have *said that*. They *could have said*: Things of this kind ought not to be sold or dis- nsed by anybody except doctors and any member of the blic who uses a thing of this kind, *except when* it prescribed by a doctor ought to be sent to prison." They uld have said that. It would have seemed a little startling at it would have protected the medical profession in that ay by saying: "This is a public danger; you may get so nd of cocaine if you inhale a specific two or three times *which there is some slight medicinal trace of cocaine*—you an get so fond of it that you may take to drinking it and ou will be poisoned." That they could have said; they ould have used *all* the army of bogeys which they have aised here before you. It is quite open to them to do it. hose would have *been legitimate means of* attack upon Mr. ucker. *That is what they could have done* when they were iscussing it; but that would not do for them. *They* had got o destroy him apparently, according to their view of it, so t *would not do to discuss him* in that way. Having taken upon themselves to say that he was a fraudulent *man*, what could they have done in order to find out whether he was a fraudulent *man or not*? They did not know whether he was or not. You may think it was either their fault or their misfortune. It is an astonishing thing that you should say about branding people with charges of fraud without knowing anything about them, but apparently that is not regarded as anything out of the way in THE LANCET Office. They had made the charge. What could they have done? First of all they got discovery in this action of all the names of his patients. They have had his books and they have ransacked his books. I am entitled to tell you in answer *to what* Mr. Bankes said just now that we should have done something or other, *I forget what it was*, about a patient of Dr. Francis who was mentioned last week, that they have been down since Friday and investigated Mr. Tucker's books about that matter to see whether there was anything there upon which they could further attack Mr. Tucker. Having that command of Mr. Tucker's books which, confident of his integrity in the matter, Mr. Tucker *readily* gave them, they had access to these 25 000 who had used the drugs and used the specific. They had his little pamphlet here with sheaves of testimonials which had been received at the end of it. They could have gone to every one of them, and you can consider for yourselves whether they probably did. They had all that means of knowing whether Tucker was doing good or doing evil, and having that means of knowledge what is the position? They do *not call* one single person who has had any direct dealing with Mr. Tucker and they do not call one single person who has used this specific—*not one*. *Having that means of* condemning him if he was guilty of this charge of theirs, they give it the go-by. My lord asked in the course of my learned friend's opening of this case whether part of the defence was to call people here said to have been injured by this specific. You heard the sort of answer which was got. *Ultimately* it was said: "We are going to call doctors who *know of* people who have been injured," and then Dr. Francis comes into the box, *and he says there* was a gentleman who said that he got a great *benefit for five years* from using this specific, whom he found using it, but *when he came under Dr. Francis's treatment* he *told him he* had better not use it so often: thereupon he *said*, "If you think that I will give it up," and Dr. Francis burned his nose. That is Dr. Francis, and that is the evidence against the Tucker specific—that there was a man who *is* not called, but who is here in London—whose name and address they do not mention to Mr. Tucker, and about whom they do not challenge him in the least—a man here in *London*, and known to them as well as to Dr. Francis, who can be put into the box if *there is any* ground at all in any dealing of Mr. Tucker with him for this charge *of fraud*; and they called an expert witness to attack Mr. *Tucker* and he is chiefly valuable to them, because he is able to slip out a statement that he knew a man who had taken it for five years and who nevertheless came to him with regard *to* a condition of asthma.

That is the evidence, really, against Mr. *Tucker*, with regard to this specific. On the one side there are the 25,000 persons who have had *beneficial* user, the 300 doctors, with Sir Stephen Mackenzie at *their head*, the testimony of the *defendants' witnesses* in the box, the testimony of the fact that Oppenheimers put up an ineffective imitation of this specific and sold it at 3*s*. 6*d*. an ounce, the testimony of witnesses *who have gratefully come here to repel this charge of fraud* and *to support* Mr. Tucker in the attack which is made upon him; and on the other side there is Dr. Francis, whose view of the *proper treatment of asthma* is that it includes the burning of the patient's nose, and who has found a person, who cannot be produced here, who *does not come here*, whom he advised not to use the specific *so often and who* thereupon said, "Very well, you are now my medical *man* and if you do not like my using it so often I will *give* it up altogether." That is the foundation in fact for all this machinery *for suggestion and alarm which has been* elaborately raised by the doctors. You have had *them* here—I will not say in a never-ending procession, but one did get a little tired even of cross-examining them. Ask yourselves with regard to those doctors, Does either of them know anything about the Tucker specific? Neither of them has ever used it; neither of them has ever—if he had asthma—tried *this remedy*; *neither* of them has apparently prescribed it; but certain of them have sanctioned the *use of it* by their patients. That is a remarkable thing, because you cannot tell, whether you are a doctor or not, whether a man *may run a risk of* acquiring the cocaine habit, as it is called, the habit of relying upon a drug; you cannot tell *that* because you are a doctor; the only thing which can show it is if it happens. But these doctors tell you "Yes, *I have allowed* my patients to go *on using it, and I have told* them they had better not use it," I think it was, "more than two or three times a day." Oddly enough that is the number of times which Dr. Tucker *prescribes for the* use *of it in his directions* which are attacked. Three times a day, he says, is about the number of times—I forget whether it is three or four, but something of *that kind*. That is the position with regard to the army of doctors. They have said, "Yes, cocaine is a poison—that is, it might do harm. It is used medicinally," they say. It is *used to a large extent* medicinally. *I venture to say if you* buy a box of lozenges for your throat you are exceedingly likely to find that one of the ingredients in it is a *trace of cocaine*, *because* cocaine, as one of the doctors told you, repeating a matter *of common* knowledge, is the product of a plant which the natives of some part of South America *use in great quantities* to strengthen themselves *or to* relieve themselves against *the consequences* of fatigue. That is what cocaine is, and they all know it. That *is the* way in which the doctors became aware of it originally, because they found the beneficial use of it by these South American natives. "But it can hurt people" they say; "you may get the cocaine habit." We did not go into the detail *of* finding out what happens to a man if he has got the cocaine habit, but we were told about atropine—that if you took enough of it it would cause madness. I *do not* know whether anybody has been taking atropine in large quantities in this case, but there has been a vehement inflammation about the sort of attack which has been made upon Mr. Tucker which might *be accounted for*, perhaps, by the resort to an excessive quantity of atropine. However, cocaine and atropine are said to be the ingredients, and then these gentlemen forthwith treat Mr. Tucker *as though* he had *taken some fluid* which was cocaine and atropine and had given it to people to introduce into their *systems*—to drink or to introduce into their vein or *something of the kind*—*regardless of* the true facts of the case. What are the facts of the case about the use *of these* things, assuming there is a trace *of cocaine* and a trace of atropine? The fact is this—that if *those doctors* are right and there is the cocaine which *they say* in *an ounce* of this fluid, in the course of three inhalations, which is what *Dr. Tucker* tells the man who uses the atomiser to take, *you will get*, *according to Dr.* Willcox's evidence, vapour, diffused throughout which there will be 3/20000th parts *of* one grain of cocaine. So that filling your lungs according to the *treatment*—*that is* what Dr. Tucker says quite clearly—*you* will inhale three times; he *says you will be able* to get into your lungs "three shots," to use an expression which I used, with a *little practice*; *so there* will be 3/20000th parts of one grain of cocaine and that will *be diffused* through a volume of vapour which will fill the lungs *and which* you are directed by Dr. Tucker to blow out, because he says if you exhale and

THE LANCET.

LONDON: SATURDAY, FEBRUARY 1, 1908.

Tucker v. Wakley and Another.

WE publish in our present issue a full account of the libel action in which we have been involved recently. It has seemed to us important that an opportunity should be afforded to the medical profession of reading the case as a whole, for in this way only can a proper conception be obtained of the value of the decision which has been registered against us. As the result of the case was a verdict for the plaintiff for £1000, and as our legal position in appealing against this verdict appears to be one of considerable complexity, we are manifestly unable to complain of the issue. Merely to complain and at the same time to take no steps for remedy would be a childish course to pursue, but we do not understand by this submission to a verdict, which verdict seems to have surprised our readers very much, that we are precluded from drawing attention to the manifest necessity that a journal, having our aims and objects and receiving the support which we do from the medical profession, should have taken throughout the attitude that we have done, whatever errors in detail we may have committed. No other attitude was possible to us, and if anybody wants to feel as certain of this as we are on reviewing the whole situation he has only to read the plaintiff's evidence in chief and in cross-examination. It is transparently clear that medical practice of the kind which is there fully described, by whatever word it is designated, must be condemned by the medical profession, and as it is our duty as well as our privilege to make ourselves the mouthpiece of that profession, such condemnation must always appear in our columns. The expressions used must be those which cannot be so easily challenged, but our policy must remain unaltered. The verdict leaves us strictly unrepentant, and Mr. Justice RIDLEY's disapprobation of our whole point of view, though invested with all the dignity lent to it by his position as a judge of the High Court, fails to inspire us with any desire of regeneration.

The case is of importance to the public, to the medical profession, and to ourselves, and we place the interested parties in their order of importance. The public and the medical profession must always seem to us, so far as regards questions of unlicensed medical practice, to be rowing in the same boat. The public have to choose the fittest people for their medical advisers. The competitors for their suffrages are two—the medical profession consisting of a body of trained and educated men tested in all the necessary scientific requirements; and the irregular practitioners, whose names are not on the Medical Register. In every profession except medicine the public would at once give their vote in favour of the properly trained body, and it is certain that as the public become more generally educated this is the view that will prevail. The nonsensical idea that the medical profession desires to become a tyrannous priesthood will disappear, and the public, growing day by day in comprehension of our hopes as well as of our performances, will perceive how valuable—how invaluable—to the community a properly ordered medical service must be. Medical men have also their lesson to learn. We have spoken of the public as growing in wisdom; already they are vastly improved in general knowledge compared to what they were even a decade ago, and they require from their medical advisers a recognition of this act. The professional man, as we have often pointed out without confining the remark to members of the medical profession, can no longer out of a superior learning counsel his clients dogmatically. He must be ready and willing to explain to them the reasons for his advice, and in this way the fact that the interests of the public and of the medical profession are identical will soon appear. The recent trial has demonstrated in the clearest way to the public the dangers that may be associated with unqualified medical practice, and they cannot fail to see that the attitude of the medical profession towards such practice is not dictated, as they are sometimes told that it is, by jealousy of the large sums of money that may be earned by their unregistered rivals, but by the sure and certain knowledge that only the trained physician can supervise the treatment of the sick.

We come now to ourselves. We have had many urgent recommendations to appeal against the verdict. Our legal advisers have not been wholly adverse to such a course, and many kind friends have suggested the institution of a subscription as a guarantee against further expenses. But despite all this we decided not to appeal. The paragraph as written contained an indefensible inaccuracy, but it was impossible for this to be explained in our columns without the extension to the methods of the plaintiff of a consideration which we were quite unable to give. Hence the action for libel became inevitable, and our admitted error would in the case of a new trial have remained as an embarrassment to us in discussing the really important features of the case. Hampered in this manner the verdict might be upheld against us even if, as seems probable, we should have had no difficulty in obtaining certain different readings of the law. It was our duty, as we conceived it then and conceive it now, to say some of the things which we said. It will be our duty to go on saying them, whatever the cost.

◆

The Importation of Unwholesome Meat Foods.

AMONGST the meat foods which are imported into this country without any restrictions being at present placed upon their admission are: (1) boneless scrap meat; (2) pork (in regard to tuberculosis); and (3) tripe, tongues, and kidneys which are heavily preserved with boron or other antiseptics. We have already referred in these columns to the reports issued from time to time by the medical officer of health of the City of London (Dr. W. COLLINGRIDGE), in which he has dealt that they have libelled him, have gone on wilfully, obstinately, upon grounds which in no way warranted their conduct, persisting in a charge of fraud, and that instead of public spirit and courage in dealing with a situation in which they have done wrong they have resorted to mean and cowardly attacks which have greatly aggravated the wrong they have done. Bearing in mind that they knew nothing about this man when they attacked him, and bearing in mind that when they had found that they had wrongfully attacked him and that there was no just charge upon his personal honesty or his personal integrity, they went on to fabricate imputations against him, to support them out of little passages here and there in the pamphlet and in the instructions, and to base them upon the bitterness with which medical men regard the unlicensed competitor, I ask you when you come to do justice to Mr. Tucker in this case not to stint the damages with which you will show resentment of conduct which is unworthy of journalism as it is of the best interests of the public or of the medical profession.

Mr. Justice RIDLEY, in summing up, said: Gentlemen of the jury, I daresay you will be glad at having arrived at the final stage of this matter, when it will be for you to decide who is entitled to succeed in this case. You must not suppose that I wish to interfere in the slightest degree with your province in that matter, because it will be for you to say in this case who is to succeed, whether the plaintiff, so that he should recover damages for the attack which has been made upon him, or the defendants upon the ground that it was a fair comment.

The first question which I shall have to ask you is this: Was this an attack upon his character at all? and in order that you may understand how that question arises I think it will be necessary that I should say just a few words upon how it is that it is a question for you. When people are attacked by way of defamatory statements there is one defence which is always attempted to be made, one which makes defamatory statements cease to be a libel, which is this—a fair criticism on a matter of public interest. It is very much analogous to the criticism upon authors' works, upon books, or upon plays, but in this case there is no question of the latter sort, the question is whether this is not a public matter upon which fair criticism is allowable so as to prevent a defamatory statement from being a libel at all; and that is what the defendant has said that it is. If that were true, and if it satisfied you that although it does attack, and is a defamatory statement, yet that it is a fair criticism upon a matter of public interest, he is entitled to succeed. But there is an exception; there is a qualification to that rule. It is this: that if the statement is not merely a defamatory one but it does attack the personal character of any individual that individual has a right to say, You shall not do that as a matter of public interest, but you must justify it if it is true. My character is sacred to me, says the plaintiff in this case, every bit as much as that of any other person who is living in this country, and it is no answer to me to say that it was a matter of public interest that I should be charged with fraud, with robbery, and with poison; that will *not do*. I am quite clear upon this matter as far as I am concerned and as far as my opinion goes, and therefore it will be necessary for you to say in the first place, Was this an attack or not upon the personal character of the plaintiff?

Before I leave that part of the case, although it is not necessary for me to argue points of law, or to explain how that point is arrived at as a matter of law, I should like to quote just two cases upon this matter. The first of them was decided a long time ago, in 1828; it was decided against Wakley, the editor of THE LANCET—the same defendants that are present in this court to-day. I do not use that as a matter of prejudice; but the editor of THE LANCET was sued in 1828 for libel. In those days there was a *London Medical and Physical Journal* current which was a rival of THE LANCET, and in THE LANCET was published a libel which is not set out in the report as far as I know, but it was sued upon as having been written in order to cast ridicule upon the journal of the plaintiff who was the proprietor or editor of the other journal: it was one against the other. The defence set up was that it was a matter of public interest and that it was fair criticism. The Lord Chief Justice in summing up the case said this: "It has been stated on the part of the defendants that the matter contained in this publication relates to the plaintiff only as an author; but still there is no doubt that a man who is an author has a right to have his character protected just the same as if he acted in any other capacity." Now you might say the same here—that it relates to the plaintiff only as the advertiser and vendor of a certain specific; still, there is no doubt that he is as much entitled to have his character protected as if he had acted in any other capacity. "However, notwithstanding that, whatever is fair and can be reasonably said of the works of authors or of themselves as connected with their works is not actionable unless it appears that under the pretext of criticising the works the defendant takes the opportunity of attacking the character and then it will be a libel." That is the case here. There is a case which I should like to add to that and then I will pass on. It was decided in 1904, where precisely the same rule appears to have been laid down by the Court of Appeal. That is the case of Joynt *v.* The Cycle Trade Publishing Company. Therefore that is how the question arises. You will be good enough to answer that according to the best opinion you can form of the libel itself.

After that there is another question—namely, whether it is a fair criticism at all, which, of course, must be submitted to you; but as to that I say nothing for the present. Now was it an attack on the character of the plaintiff is the first question, because you will see that if it is, there being no justification, it should entitle the plaintiff to a verdict according to the authorities which I have quoted to you and according to a most beneficent and proper principle of the law as I understand it. Therefore, I shall ask you first of all to consider the words of the libel and the way in which they have been construed by the witnesses put before you with a view of saying whether this was an attack upon the character of the plaintiff or whether it is merely, as was put by Mr. Bankes in his very able speech before you, merely an attack on the advertisements of quack medicines and as a statement not of fraud meaning dishonesty but a statement that there was a fraud in the sense of statements calculated to deceive put forward in those advertisements. I think I do not unfairly state the argument which he puts before you. He says: It was not fraud in the plaintiff that we alleged, but fraud in the system—namely, advertisements which contained statements calculated to deceive; that is what we said: we did not say he was fraudulent, and we did not say anything against his character, but we said it was the advertisements which were bad; we said it was the system which was bad, and we did not say that he was; the word "fraud" was indeed used of him, but only in the sense which I have indicated, and the other words, such as "quack," rob, and "poison," were not used of him at all. Before I refer to the evidence let us test that for a moment. Supposing this had not been medicines at all, but supposing it had been provisions—a provision dealer. He is subject to the Adulteration Acts as the vendor of medicines is subject to the Pharmacy Acts. If he offends against the Adulteration Acts he may be prosecuted accordingly. Supposing you put in the newspaper of a provision dealer, "He is a fraud; he sells goods which poison the public; he has robbed the public." It is *no answer to say* that is a criticism on a matter of public interest and a fair criticism, because you attack his character. Is it not the same here? Which is it therefore; is this an attack upon him or upon a system? Now let us look and see for a moment, forgetting that it is medicine at all, "Quack advertisements"; no doubt I think it is fair to say that the gentleman who wrote this article had quack advertisements in his mind, I agree, for he heads it "Quack advertisements." "In the course of an inquest held at the beginning of the year it was stated that a labourer who had died from consumption had been using Dr. Tucker's asthma specific inhaler, for which he had given according to a newspaper report which has reached us, three guineas, while the material with which he had sprayed himself cost him 8*s.* an ounce. Dr. F. J. Waldo, the coroner, rightly stigmatised this kind of dealing as a fraud and it is a humiliating thing for journalists to remember that such frauds could not be committed with any profit to the quack save with the coöperation of the press." I do not think that I need read the next sentence at this moment but I shall have to read it afterwards. It goes on to say: "The remedy is in the hands of the public, who have only to signify their displeasure at reading in their journals invitations to be robbed and poisoned to find those invitations immediately

THE LANCET.

LONDON: SATURDAY, FEBRUARY 1, 1908.

Tucker v. Wakley and Another.

WE publish in our present issue a full account of the libel action in which we have been involved recently. It has seemed to us important that an opportunity should be afforded to the medical profession of reading the case as a whole, for in this way only can a proper conception be obtained of the value of the decision which has been registered against us. As the result of the case was a verdict for the plaintiff for £1000, and as our legal position in appealing against this verdict appears to be one of considerable complexity, we are manifestly unable to complain of the issue. Merely to complain and at the same time to take no steps for remedy would be a childish course to pursue, but we do not understand by this submission to a verdict, which verdict seems to have surprised our readers very much, that we are precluded from drawing attention to the manifest necessity that a journal, having our aims and objects and receiving the support which we do from the medical profession, should have taken throughout the attitude that we have done, whatever errors in detail we may have committed. No other attitude was possible to us, and if anybody wants to feel as certain of this as we are on reviewing the whole situation he has only to read the plaintiff's evidence in chief and in cross-examination. It is transparently clear that medical practice of the kind which is there fully described, by whatever word it is designated, must be condemned by the medical profession, and as it is our duty as well as our privilege to make ourselves the mouthpiece of that profession, such condemnation must always appear in our columns. The expressions used must be those which cannot be so easily challenged, but our policy must remain unaltered. The verdict leaves us strictly unrepentant, and Mr. Justice RIDLEY's disapprobation of our whole point of view, though invested with all the dignity lent to it by his position as a judge of the High Court, fails to inspire us with any desire of regeneration.

The case is of importance to the public, to the medical profession, and to ourselves, and we place the interested parties in their order of importance. The public and the medical profession must always seem to us, so far as regards questions of unlicensed medical practice, to be rowing in the same boat. The public have to choose the fittest people for their medical advisers. The competitors for their suffrages are two—the medical profession consisting of a body of trained and educated men tested in all the necessary scientific requirements; and the irregular practitioners, whose names are not on the Medical Register. In every profession except medicine the public would at once give their vote in favour of the properly trained body, and it is certain that as the public become more generally educated this is the view that will prevail. The nonsensical idea that the medical profession desires to become a tyrannous priesthood will disappear, and the public, growing day by day in comprehension of our hopes as well as of our performances, will perceive how valuable—how invaluable—to the community a properly ordered medical service must be. Medical men have also their lesson to learn. We have spoken of the public as growing in wisdom; already they are vastly improved in general knowledge compared to what they were even a decade ago, and they require from their medical advisers a recognition of this act. The professional man, as we have often pointed out without confining the remark to members of the medical profession, can no longer out of a superior learning counsel his clients dogmatically. He must be ready and willing to explain to them the reasons for his advice, and in this way the fact that the interests of the public and of the medical profession are identical will soon appear. The recent trial has demonstrated in the clearest way to the public the dangers that may be associated with unqualified medical practice, and they cannot fail to see that the attitude of the medical profession towards such practice is not dictated, as they are sometimes told that it is, by jealousy of the large sums of money that may be earned by their unregistered rivals, but by the sure and certain knowledge that only the trained physician can supervise the treatment of the sick.

We come now to ourselves. We have had many urgent recommendations to appeal against the verdict. Our legal advisers have not been wholly adverse to such a course, and many kind friends have suggested the institution of a subscription as a guarantee against further expenses. But despite all this we decided not to appeal. The paragraph as written contained an indefensible inaccuracy, but it was impossible for this to be explained in our columns without the extension to the methods of the plaintiff of a consideration which we were quite unable to give. Hence the action for libel became inevitable, and our admitted error would in the case of a new trial have remained as an embarrassment to us in discussing the really important features of the case. Hampered in this manner the verdict might be upheld against us even if, as seems probable, we should have had no difficulty in obtaining certain different readings of the law. It was our duty, as we conceived it then and conceive it now, to say some of the things which we said. It will be our duty to go on saying them, whatever the cost.

◆

The Importation of Unwholesome Meat Foods.

AMONGST the meat foods which are imported into this country without any restrictions being at present placed upon their admission are: (1) boneless scrap meat; (2) pork (in regard to tuberculosis); and (3) tripe, tongues, and kidneys which are heavily preserved with boron or other antiseptics. We have already referred in these columns to the reports issued from time to time by the medical officer of health of the City of London (Dr. W. COLLINGRIDGE), in which he has dealt which may exist between an attack upon a system and upon the man who does it. I would suggest as to that that the man who takes upon himself to attack a system has this burden upon him, that he does not mix up with that criticism the character of any one person who has done it, because if he does he is subject to this law, that he must justify that which he says to the detriment of any other person, whereas if he merely confines himself to a criticism of the system he is entitled to say: "I am only doing that which it is my right to do; I am putting forward in the interests of the public a fair criticism upon a matter of public interest." That is the nature of this case. Which is it? Is it a matter in which the man's character is brought in or is it not?

The next question is this: Was it a fair criticism upon a matter of public interest? I shall ask you to answer that question as well because it is for you, and not for me, to answer it. Supposing it was not an attack upon the character of the plaintiff; still the defendant must show that it was a fair criticism. That is his defence. Will he be able to make it out? Will he be able to get under the general rule, having escaped the exception which I have been putting before you now as the one which prevents him raising the other defence? Was it a fair criticism upon a matter of public interest? It is in that way that the general question which we have been discussing in this case arises and it is in that way that it becomes material to find out what was the state of facts about the use of this specific and what can be said about it by the doctors. The doctors have established, I should think to your satisfaction, that in their opinion—mind you, it is in their opinion, and in their honest opinion—there is a risk in the use of this specific. It is not altogether established as a fact, because, on the other side, it is sworn that there is not. There are, however, as it is said, circumstances in which it has been found to be so among the patients of Dr. Francis, and possibly among the patients of one other medical gentleman who has been called; but that point does remain in doubt, because it is challenged on the other side by other medical men who say that in the quantities in which this cocaine could possibly be taken—in the utmost quantities—under the treatment suggested for the use of this specific it could not possibly injure anyone; but that is the position of affairs. Now I think it is necessary in order to see whether this is a fair criticism to make out some sort of summary of what the state of facts is on one side and the other before you come to a final conclusion as to whether or no the thing is justifiable as a fair criticism or not. Let us see what it is that is said about him from this point of view. It is necessary now to read the sentences which I previously omitted: "A correspondent has recently sent us a collection of advertisements of so-called proprietary medicines which he had cut from papers of high reputation in the country, inviting our opinion of them. Our opinion is that the misery wrought by quacks must be unknown to a good many proprietors of newspapers or they would hardly share with the quacks the plunder extracted from the public, mainly from the sick poor. The remedy is in the hands of the public, who have only to signify their displeasure at reading in their journals invitations to be robbed and poisoned to find those invitations immediately cease. But the public are largely uninstructed and credulous and, alas, those responsible for the conduct of many of our journals take no trouble to enlighten them. They prefer to regard all protests against quack advertisement as emanating from the narrowness of the medical profession; this is certainly a convenient faith, but how it can be truly held by educated people passes our comprehension." Now, gentlemen, I think I may safely say that in those words there is not one hint, not one suggestion, of the faintest possible character, that any good had ever been done by this medicine, and it is as though the curtain had been pulled down permanently before the eyes of the man who wrote this advertisement hiding from him the fact that there are 30 000 people who have been benefited by the use of it. There is not one word to suggest that any human being was ever the better for the use of it. He says: "You are robbed and poisoned; you are uninstructed; you are credulous; plunder has been extracted from you." It is all on the wrong side. That may be true to a certain extent. It has its foundation in the evidence given before you that there is a trace—a certain quantity—of three poisons in this specific; but, gentlemen, is it the fair thing to do to leave out the good side, and to put in only the bad? We have it before us—in fact, we have it in this pamphlet and we have it upon the general evidence in the case—that whilst some people are said to have been, and one person rather more than said to have been, the worse for the use of this drug in that he has contracted an undue liking for it which will cause him to have the cocaine habit, and whilst we have been told by the medical men that it is the result of using such a thing we have been told that there is an immense quantity of good which has been done by it. Where is that in this article? I should have thought that in criticising this matter from the public point of view you ought to say this: A man may invent a specific by his own learning, by his own experience it is true, yet by an accidental piece of good fortune which has not befallen other men as eminent as himself; it may be that it has got poison in it, we must be protected against that, and we must see that he is prosecuted under the Pharmacy Act; we must see that that is done to protect the public; but we must not shut our eyes to the fact that there are thousands of people in this country, who by the use of that specific have become able men, able to do their own work, to rise in the morning, and do their day's work, and to take their rest at night owing to the invention of this specific. Where is that in this article? There is not one word about it; and it is no answer to say that the writer did not know it because he ought to have done when he wrote that article. That is the way in which this question arises, which by no means is to be answered in favour of the defendant, merely because you do not think there is a personal attack upon the character of the plaintiff. Let us see. I have before me here a long list of witnesses who were called before you who spoke to the benefit which they had derived from this specific. I think it is true to say, as Mr. Bankes did, that they did not use it in great quantities so far as the evidence has proved before you. It may be true, but without one exception, they all of them spoke to the benefit which they had derived from this specific which they could get from no other. There are 15 of them—barristers, peers, solicitors, a commercial traveller, people from all ranks of life. Some of them have used it for five years, six years, seven years; some only for 15 months, and some for even a shorter period. But there it is, and not one has felt the slightest evil effect from it. The doctor who was called, whose name has been mentioned by Mr. Bankes in particular, Dr. Clark—I think, perhaps, it might be advisable to read what he said, but I do not care to do so, for I think if I did, I ought to read the evidence of many others. I do not think it is necessary that I should, but I believe I have fairly put before you what is the effect of their evidence. No I am not going quite to leave it there, but I am going to say that there are 143 testimonials in this book which is at your liberty to read, if you think proper, from people in England, Wales, Scotland, and Ireland. I am not going to read them. They are of all sorts and all kinds; but I thought that I would pick out one from each country and read them to you. I do not know whether any objection will be made on the part of the defendant to my doing so? if so, I will not do it.

Mr. ELDON BANKES: I do not think my learned friend would have used them in that way as evidence.

Mr. Justice RIDLEY: Then I will not use them.

Gentlemen, I think you are entitled to read them if you like, and I shall leave it there. Some of them are of the most touching character. I do not mind saying this much: I would rather have one of those testimonials put in the scale than I would have the adverse opinion of a doctor. If the question was, Have I been guilty of something wrong in disseminating this specific? one of those testimonials weighs that opinion down. There I leave it. This man is entitled to say that the good side of the business which he has been transacting has been left out; he is entitled to say that. It is for you to say whether you agree with him. That is the position.

Having regard to that being the case, what is said on the other side as a fact against it? It is true it is made out that this is a poison administered in it. It is true that it is made out that it ought to be under the Pharmacy Act. What else is said?—that it is administered as a fraud in this sense that people have to pay for it more than it is worth, and Mr. Bankes says: You are asking the poorer classes to pay no less than £3 for the atomiser and the first two ounces and 8s. for the subsequent ounce when they cannot afford it. I am not going to read

BULSTRODE has visited practically every sanatorium and hospital for tuberculosis or diseases of the chest in England and Wales; he has discussed and investigated various aspects of the prevention of tuberculosis with medical officers of health wherever special lines for attacking this problem have been developed; and he has obtained much detailed information as to the conditions associated with the prevalence of pulmonary tuberculosis in foreign countries. The bulky volume now issued presents a mass of important data derived from these sources, together with the results of Dr. BULSTRODE's own studies, and it furnishes an invaluable critical summary of the present state of our knowledge regarding the etiology of pulmonary tuberculosis and the different factors which appear to be concerned in the maintenance, diminution, and prevention of this disease.

We propose to devote some special articles to certain portions of the report, particularly those which deal in detail with sanatoriums, their construction, management, finance, records, and classification of results. Here we may note that Dr. BULSTRODE is satisfied from the evidence which he has collected as to the curative results which are so frequently secured by sanatorium treatment if only the case is seen at a sufficiently early stage, and also with regard to the decided amelioration which is often produced by the sanatorium *régime* in more advanced cases. Sanatorium statistics as to cases which are discharged as "improved," "cured," "fit for work," and the like are, however, notoriously uncertain and difficult of comparison, and it is to be hoped that the section of the report which relates to tabulation of results will do something to enable statistical information regarding these institutions as a whole to be compiled in future with some degree of confidence. In considering the effect which the treatment of cases of pulmonary tuberculosis in sanatoriums, municipal institutions, and Poor-law infirmaries may have in checking the prevalence of the disease the report speaks with considerable caution. It is true that by these means potentially infectious persons may for longer or shorter periods be isolated from the community and that many will there be educated in precautions against spreading infection when they return to their homes or to their work. But it must be admitted that administrative measures for the prevention of pulmonary tuberculosis during the past decade have sometimes been based rather too exclusively on the assumption that the one thing essential to the control or extinction of this disease is the safe disposal of visible sputa. It is useful to have placed before us, as in this report, other and not less important considerations. The death-rate from pulmonary tuberculosis has been declining at a fairly uniform rate throughout England and Wales for over 50 years. A similar decline, steeper or more gradual, has occurred in individual counties and towns and in particular foreign countries. Contrary perhaps to expectation, the rate of decline has not been materially accelerated either as a consequence of the new era of sanitary administration which began in the late "seventies," or as a result of the discovery of the tubercle bacillus in 1882, or after the general recognition in England of tuberculosis as an infective process. So far as is disclosed by the data available, it has not been conspicuously quickened in particular localities in consequence of special local methods for the repression of pulmonary tuberculosis which have only come into operation in recent years. The evidence that the tuberculous person with expectoration is a direct source of serious danger to his associates is far from complete; our experience as to the communication of pulmonary tuberculosis by husbands to wives or *vice versâ*, like our experience as to the spread of pulmonary tuberculosis among nurses and attendants in hospitals for consumption, tends to the contrary conclusion, though we rely on the figures before it was customary to enjoin any special precautions in regard to sputa.

Infection from person to person, whatever its effect may be, seems as likely to result from aerial transmission of virulent tubercle bacilli by invisible droplets produced by coughing or speaking as from dust containing comparatively inert bacilli derived from dried sputa. Direct infection of the lungs by way of the respiratory passages cannot be demonstrated to be the customary method of infection in pulmonary tuberculosis; it is probable that the infective bacilli often reach the lungs as a result of infectious matter having been swallowed and having reached the blood stream by way of the thoracic duct. In modern conditions of life many healthy people carry about cured tuberculous lesions, the result of a past lung infection which gave no clinical sign of its identity with pulmonary tuberculosis. The part played by bovine tubercle bacilli in the production of pulmonary tuberculosis has yet to be determined, but the evidence suggesting that this disease in adults may result from an infection of bovine origin in childhood cannot be overlooked. It is, of course, impossible to present the conclusions of a closely reasoned report in a few lines, but it seems clear that Dr. BULSTRODE, in discussing considerations such as the above, desires very properly to insist that from the point of view of modern preventive medicine the condition of the host in regard to the parasite must be considered at least as important as the repression of the parasite itself. If, setting aside speculative questions of change of type of the disease or development of racial immunity, some general phrase is sought to explain the steady diminution of the mortality from pulmonary tuberculosis in the last half century much may be said for the broad term, "improved social conditions." As acute poverty has decreased, food becomes cheaper, temperance more common, and the air of dwellings fresher; people have to an increasing extent approximated towards those conditions of living which recent sanatorium experience has shown to be most desirable in order that tuberculous infection may be conquered by the host at an early stage. Dr. BULSTRODE'S study of the behaviour of pulmonary tuberculosis in the German Empire and its relation to the improved social conditions of the German working class is in this and other respects one of the most instructive portions of the volume. In a different way, unhappily, the experience of Ireland appears to point to the same conclusion.

The chapters in the report which relate to the discussion of the results obtained from the local notification of pulmonary tuberculosis have special interest. The beneficial effect of notification in securing the earlier treatment or cure of individual cases and the diminution of

The FOREMAN of the JURY: May we take your paper with the questions on, my lord?

Mr. Justice RIDLEY: Yes; I will hand it to you. Here is the letter of Cushing asking for the stuff. I do not think I need hand you the letters.

The JURY: No.

(The jury retired to consider their verdict at 3.7 and returned into court at 3.39.)

The ASSOCIATE: Gentlemen, are you all agreed?

The FOREMAN of the JURY: Yes.

The ASSOCIATE: Do you find for the plaintiff or for the defendants?

The FOREMAN: For the plaintiff.

The ASSOCIATE: For what amount?

The FOREMAN: £1000.

Mr. Justice RIDLEY: Did you answer the particular questions put to you?

The FOREMAN: Yes, my lord.

Mr. Justice RIDLEY: Will you give me the answers to them?

The FOREMAN: "Yes" to the first; "No" to the second.

Mr. Justice RIDLEY: The second question you answer with a negative?

The FOREMAN: Yes, my lord.

Mr. Justice RIDLEY: It is not a fair criticism, you say. (The answers were handed to his lordship.)

Mr. SMITH: On that I ask your lordship for judgment. I think it was my special jury. Your lordship will certify for a special jury?

Mr. Justice RIDLEY: Yes. (To the jury:) I can discharge you, gentlemen. The parties came to an agreement which will be satisfactory to you, I hope.

Mr. HUGH FRASER: I ask your lordship for a stay of execution having regard to the fact that there are important questions of law to be dealt with in the case.

Mr. Justice RIDLEY: The jury have thought that it is not a fair criticism.

Mr. HUGH FRASER: As I understand, the jury have found Yes to the first question and No to the second.

Mr. Justice RIDLEY: Yes, that is so; they have found that it was an attack on the character of the plaintiff and that it was not a fair criticism on a matter of public interest. That means to say in any case you had not criticised fairly.

Mr. HUGH FRASER: Of course, your lordship appreciates the point taken by my learned leader?

Mr. Justice RIDLEY: Yes, perfectly. I think if that had been the only point I should have been more inclined to agree, but they found that even assuming you are right you have not criticised it fairly.

Mr. HUGH FRASER: Put shortly, our point was this, that in an attack on a system you may necessarily attack the individual conducting the system, and if that view of the law is correct, with respect to your lordship the direction given to the jury would be wrong.

Mr. Justice RIDLEY: I know it would, but then the second question puts the matter out of all difficulty, does it not? What do you say, Mr. Smith?

Mr. SMITH: I do not desire to make any particular objection to my friend having a stay of execution.

Mr. Justice RIDLEY: I will stay execution if you can make anything of it.

Mr. SMITH: On the usual terms.

Mr. HUGH FRASER: Yes, on the usual terms.

Mr. Justice RIDLEY: I indicate no opinion beyond what I have said, but I think I summed it up fully. I will grant the stay.

Mr. SMITH: That, of course, will be on the usual terms?

Mr. Justice RIDLEY: What are they?

Mr. SMITH: The money, I imagine, will be paid into court and the costs will be paid on the usual undertaking.

Mr. HUGH FRASER: Does my friend want the money in court having regard to the position of the defendants?

Mr. SMITH: No, the money need not be in court, but I think the costs should be paid on the solicitors' undertaking.

Mr. Justice RIDLEY: Yes, certainly.

Mr. SMITH: There is one thing I should mention to your lordship. Your lordship knows that some evidence was taken on commission. I do not want to trouble your lordship with the matter. I think my learned friend agrees that possibly that might be left to the Master. It is a question of the additional costs occasioned by the commission.

Mr. Justice RIDLEY: Was there any order made about it?

Mr. SMITH: The order made by your lordship was, I think, on an application by my learned leader that the case should not be taken before the conclusion of last sittings, and by my learned friend Mr. Duke, who led me, as a condition asked that Lord Ashburnham, who was not in a very robust state of health, should be allowed to have his evidence taken on commission if necessary. What happened next was that we got a letter from Lord Ashburnham saying that although he hoped to be here and would be here if he could, his health was not very strong, and he thought it would be safer, as he was developing a chill, that we should take his evidence on commission, and under those circumstances we thought we should not be well-advised in running the risk; so we applied for his evidence. Your lordship sees that his evidence was valuable and he was ultimately able to come. I think that is the only question which arises.

Mr. HUGH FRASER: Lord Ashburnham's evidence was taken on a Saturday on commission, the case was in the list on Monday, and actually started last Wednesday.

Mr. Justice RIDLEY: I will leave it to the Master, I think. The stay will be on the usual terms. How many days do you wish to have—eight days?

Mr. SMITH: Ten days, my lord.

Mr. Justice RIDLEY: It must be eight days.

Mr. SMITH: Very well, my lord.

Looking Back.

FROM

THE LANCET, *SATURDAY*, Jan. 30th, 1830.

THE FIRE KING.

To the Editor of THE LANCET.

SIR,—I am ready to drink oil heated to 350 degrees, and to administer my antidotes to various poisons given to animals. You say that my feats respecting the oven, and oil, are unworthy the fire king.[1] Now, Sir, if *you* or any of your friends will enter, and *remain* in the oven with me at 600, I will then go in at 800 *degrees*, and if anyone will drink oil at 350 degrees I will then drink it at 600 degrees.

You may bring two dogs, and yourself administer the prussic acid. Should one dog die, and the other (taking my antidote) live, I hope you will then allow that I am *not* an impostor. Both the dogs must be left with me three days after the experiment. Your obedient Servant,

Thursday, Jan. 28th. XAVIER CHABERT.

MONSIEUR CHABERT must recollect that the Editor does not profess to be a Fire King, or a Fire King's *subject*, and feels no inclination, therefore, to *remain* in an oven at 350°. Nevertheless, he is deeply interested in the subject of poisons and their antidotes, and therefore begs of M. Chabert to name an early day on which he may attend with the two dogs, and a few gentle doses of prussic acid. M. Chabert has forgotten to state whether he will drink a tumbler or two of boiling water.

---

MEDICAL SICKNESS AND ACCIDENT SOCIETY.—The usual monthly meeting of the executive committee of the Medical Sickness and Accident Society was held at 6, Catherine-street, London, W.C., on Jan. 17th. There were present Dr. F. de Havilland Hall (in the chair), Mr. J. Brindley James, Dr. Walter Smith, Dr. M. G. Biggs, Dr. H. A. Sansom, Dr. J. W. Hunt, Dr. M. Greenwood, Mr. F. S. Edwards, Dr. St. Clair B. Shadwell, Dr. F. J. Allan, Mr. Edward Bartlett, Mr. J. F. Colyer, and Dr. J. B. Ball. The accounts presented showed that the sickness experience of the society during the month of December had been exceptionally good. The claims were rather less numerous than is usual at that period of the year, and as they were in nearly all cases of very short duration the amount disbursed as sick pay was well under the expectation. The business during the year 1907 has been very good, an unusually large number of new members have joined the society, and a substantial increase in the funds has been made. Prospectuses and all information may be obtained on application to Mr. F. Addiscott, secretary, Medical Sickness and Accident Society, 33, Chancery-lane, London, W.C.

rendered practically non-combustible by the use of some application for all trains and tracks is imperative and the public have a right to expect that every possible means of protection against the awful risks of fire are taken.

DEATH OF SIR THOMAS McCALL ANDERSON.

THE death took place with startling suddenness on Saturday night, Jan. 25th, of Sir Thomas McCall Anderson, professor of medicine in the University of Glasgow. He had been dining with the Glasgow Ayrshire Society in the St. Enoch Hotel and had even proposed the last toast of the evening. When the company broke up he was in the act of descending the stair from the dining-room when he was seen to stumble and within a few minutes he was dead. We shall in a later issue of THE LANCET give an appreciation of the work of this great Scottish physician.

THE PERCUSSION SIGNS OF EARLY APICAL TUBERCULOSIS OF THE LUNGS.

WE have received from Dr. Guido Rheiner of St. Gall, Switzerland, an interesting communication in which he points out the importance of careful study of the physical signs at the apices of the lungs in cases of doubtful pulmonary diseases, especially from the standpoint of the examiner for life insurance companies. He quotes the interesting observation of Naegely of Zürich, who found in the course of 500 necropsies on persons over the age of 18 years the enormous percentage of 97 who showed indications of previous tuberculous affection, and he emphasises the danger of these occult lesions in many persons. He refers to the statistics of a German life assurance company from 1857 to 1894 in which it appears that out of 20,124,165 policy-holders 17·28 per 1000 males and 15·76 per 1000 females died in the course of the first year, of which 3·51 and 3·58 per 1000 respectively were due to tuberculous disease of the lungs. As shown by Virchow the earliest deposit in the lungs usually occurs in the form of miliary tubercles in the mucous membrane of the smallest bronchi, and it is not until later that inflammatory processes around lead to areas of consolidation. Although these may early give rise to a few auscultatory signs Sahli of Berne stated that these isolated consolidated spots even when superficial must be at least some square centimetres in size in order to give rise to distinct dulness. Dr. Rheiner insists on the great importance of careful percussion about the apex, and especially by means of a method described by Krönig of Berlin in 1889. It is well known that if the head be held up the extreme apex of the lung reaches from three to five centimetres above the clavicle, forming practically a small cone. Percussion of this region in the ordinary way simply maps out the vertical extent of this cone but gives no information as to its breadth or as to its circumference, both of which may be lessened by cicatrisation. In order to determine these the examiner should stand beside the patient and percuss in various directions, mapping out the resonant area from the dulness due to the shoulder and surrounding parts. The line so obtained is normally found to extend from the inner part of the clavicle, mounting gradually towards the anterior margin of the trapezius muscle until it reaches the summit of the shoulder, from which it curves downwards to reach the vertebral column at a point between the second and third dorsal vertebræ. In mapping out this line it is recommended to commence percussion on a dull area and percuss towards the resonant regions, using the third phalanx of the right middle finger as a pleximeter and tapping firmly on the nail with the left middle finger. The line is found to cross the clavicle and extend backwards to the end of the inner third of the spine of the scapula, the accurate determination of its situation being more difficult in this region than in front. The extent of this resonant area and the situation of this boundary line delimiting it are in normal persons identical on the two sides and they are capable of accurate determination, since if careful observers compare their results there is not as a rule a difference of more than half a centimetre. Dr. Rheiner finds that this area is contracted and the boundary line displaced when there is old tuberculous disease. It is increased in emphysema, while in early tuberculous disease although its extent is unchanged the note obtained in this region is altered. Although these observations do not afford conclusive evidence they may often lead to an early lesion being discovered and its nature being established by other means of diagnosis. The point urged by Dr. Rheiner of the importance of using every means to render diagnosis of tuberculous apical lesions more certain in as early a stage as possible is one to bear in mind not only from the standpoint of the life insurance companies but also from that of the patient, since it is well established that the earlier the disease is recognised the more effective treatment is likely to be in leading to a permanent arrest. There is no doubt that percussion of the apices of the lungs is a matter of considerable difficulty and that it is often very incompletely carried out, so that valuable information which might be acquired by its aid is overlooked. Unfortunately, also, the personal equation in percussion is difficult to eliminate. Dr. Rheiner's championship of Krönig's method, however, should serve to draw attention to its value.

A GREEK MEDICAL AUTHOR OF THE SECOND CENTURY.

THE Berlin Academy will shortly commence the publication of a new complete edition of all known Greek medical works, produced with as much scholarly care and collation of all known manuscripts as have hitherto been devoted to the remains of historical and literary classic authors. In preparation for this great corpus of Hellenic medicine the German editors who are taking part in the task occasionally print short preliminary notes upon the subject. Thus in the philological journal *Hermes* Herr Wellmann has presented a most interesting summary of the work of the second century A.D. physician Herodotus, who is praised by Galen. The object of Herr Wellmann's essay is to assign to this Herodotus the admirable, but hitherto anonymous, medical treatise *Διάγνωσις περὶ τῶν ὀξέων*, which is contained in two manuscripts preserved in Paris, one of which was brought from the Greek Monastery on Mount Athos by Minoides Mynas. Many passages of this work are identical with parts of the collection of medical authors made by Oribasius at the request of the Emperor Julian. Herr Wellmann shows that the quotations from Herodotus are so cited as to indicate that he came between Soranus and Philumenus, and therefore that he lived in the second century, to the early part of which, as Galen quotes him, he must be assigned. Finally, by the identity of style and language between the treatise in the Paris codices and the extant quotations of Herodotus Herr Wellmann proves Herodotus to be the author of the work.

THE FIRST OPERATION FOR APPENDICITIS.

THE question is often asked "When was the first operation for appendicitis performed?" We have been asked it this week almost exactly in these words. The answer must depend greatly on what is meant by operations for appendicitis. If we may include among such operations the evacuation of an abscess resulting from an attack of appendicitis we must go back a very long way indeed. Doubtless many such abscesses were opened ages before any record of such operations was made. Aretæus, who flourished some 50 years before the commencement of the Christian era, says: "I once made an incision into an abscess in the with the question of the importation of frozen boneless meat packed in boxes which reaches this country from America. Mere inspection of this particular form of meat can afford no safeguard and the only satisfactory plan of dealing with it would appear to be to exclude it entirely from the country. This view is shared by Dr. G. S. BUCHANAN in a valuable report recently submitted to the Local Government Board. As he points out, the matter is one with which the enactment of the Public Health (Regulations as to Food) Act, 1907, will enable the Local Government Board to deal. At the present time the traffic in this commodity is small and to prohibit its importation would cause little interference with trade. Boneless scrap meat regarded as a portion of our imported meat-supply is, he says, practically a negligible quantity and as yet it is only a small portion of the imported meat which finds its way to makers of sausages, minced meat, and like articles. If it is urged that this scrap meat is after all for the most part wholesome, the obvious answer is that in that case it is free to come in other forms—for example, as joints or portions of meat readily identifiable with definite parts of the dressed carcass—which are less open to suspicion. In the case of foreign scrap meat no inspection in this country can suffice to detect disease in the animals from which the meat was derived and no information can be gained as to the unwholesome conditions under which handling, chemical treatment, packing, and the like may have been carried on in the country of origin. As it is, the frozen meat packed in boxes has been found to show signs of decomposition at an early stage after it has been thawed and it is undesirable that such meat should be accessible to the sausage or mincemeat maker.

Similar difficulties arise in regard to the inspection of imported pork, the proper place for judging the condition of pigs being the slaughter-house in which the carcass can be inspected together with its various organs. The administrative difficulty which is encountered in regard to imported pork results mainly from (*a*) importation of pork in *portions* of carcass—for example, the American pork alluded to; and (*b*) importation of "*stripped*" *carcasses*—i.e., pigs from which the head has been removed low on the shoulders so as to take with it the lymphatic glands which are commonly the seat of tuberculosis, or of carcasses which though having the head attached have been deprived of the lymphatic glands, these having been cut away no doubt in order that no question of condemnation on account of tuberculosis may arise. Again, the powers conferred upon the Board by the Public Health (Regulations as to Food) Act, 1907, would permit of useful interim measures being taken in regard to checking this undesirable importation. It is suggested that pork imported as carcasses should be required to consist of entire carcasses including the head and lymphatic glands about the throat, and that pork imported in portions less than the entire carcass should be inclosed in boxes, barrels, bags, or other receptacles bearing an official mark which has been accepted by the Board. The officers of the Board, of course, would be able to satisfy themselves as to the authenticity and genuineness of this official mark.

Finally, in this recent report the question of the importation of tripe, tongues, and kidneys heavily preserved with antiseptics has been dealt with. Having regard to the fact that tripe forms a considerable item in the food of the working classes, something over 10,000 tons from all sources being consumed in a year in the United Kingdom, the question of its wholesomeness is of considerable importance. The conditions of its manufacture and preparation for food purposes in this country appear on the whole to be generally wholesome and cleanly. It is quite a different state of things, however, in regard to tripe which is imported already boiled into this country. In order to prepare such a readily decomposable commodity as cooked tripe for the British market it is packed in kegs containing strong solutions of boron preservative and this treatment results in the tripe absorbing and retaining considerable amounts of boric acid. The quantity found was seldom less than 60 grains per pound and sometimes it was over 150 grains per pound. As is pointed out, a quarter of a pound of this tripe—which may be considered a moderate meal—must often contain more than the maximum dose of boric acid prescribed for an adult by the British Pharmacopœia. The uncooked "barrel tripe" which is imported into this country chiefly from America is also preserved in strong solutions of boric acid, while some tripe imported from Canada contained sulphurous acid in addition. The observations made in regard to foreign preserved tripe appear to apply with equal force to imported tongues and kidneys which are preserved in a similar antiseptic liquor. The Public Health (Regulations as to Food) Act, 1907, may again be turned upon this kind of importation with doubtless distinct advantages to the health of the community. This important inquiry, for the thoroughness of which Dr. BUCHANAN deserves a word of praise, illustrates what a valuable step in public health administration was taken when this much-needed extension of the Public Health Act was made at the instigation of Mr. JOHN BURNS. The questions raised are obviously of the first importance from the point of view of public health and that being the case any political or economic considerations which may be involved in the reforms indicated cannot seriously be entertained.

◆

Sanatoriums and Tuberculosis: Dr. Bulstrode's Report to the Local Government Board.

IN a leading article last week we referred to the comprehensive inquiries into epidemiological questions which from time to time have been made, under Mr. W. H. POWER's direction, by medical inspectors of the Local Government Board and to the great public utility of work of this kind. A notable example has been furnished by the issue from that department of a volume on "Sanatoria for Consumption and Certain other Aspects of the Tuberculosis Question." Its author, Dr. H. TIMBRELL BULSTRODE, has been engaged for five years in official inquiries into this subject and his initial qualifications for dealing with it may be judged from his well-known series of Milroy lectures which were published in our columns in 1903. Dr.

that male tsetse flies are far more commonly captured than females and believes that this fact may account for the failure of observers to trace the sporogony of the trypanosomes of mammals. It has been shown by Léger and Brumpt that the trypanosomes of fishes undergo a true sporogony within the body of leeches. Although Dr. Sambon cannot be said to have brought forward direct evidence establishing his contention, yet there would appear to be presumptive evidence that some further development of the trypanosome does occur in the insect, and this indicates the necessity for more extended observation upon the life-history of these parasites outside their vertebrate hosts. The matter is one of practical importance, for Dr. Sambon states that the transmission of both nagana and sleeping *sickness may take* place through the progeny of infected female tsetse flies—in other words, that the infection may be transmitted in these flies hereditarily. The importance of destroying the tsetse flies is emphasised by the success which attended the destruction of mosquitoes in malaria-infected districts, and Dr. Sambon believes that when all the life habits of tsetse flies are known it should be easier to destroy them than mosquitoes. His report is a suggestive contribution to the important subject of which it treats.

CHELSEA AND THE NOTIFICATION OF BIRTHS ACT, 1907.

DURING the session of 1907 an Act was passed known as the Notification of Births Act. The chief provision of the Act is devoted to making it compulsory for the father of any child, if he be residing actually in the house at the time of the birth, to give written notice of such birth within 36 hours to the medical officer of health of the district. Also, any person in attendance upon the mother at the time of the birth or within six hours after the birth has to give notice as well. Penalties are provided by the Act for omitting notification. But a person shall not be liable to a penalty if he satisfies the court that he had reasonable grounds to believe that notice had been duly given by some other person. During the passage of the Bill through the House of Commons it was pointed out that the Bill threw a new duty upon medical men and that not only would they get no fee but they would be liable to a penalty for omitting to comply with the provisions of the Bill. An understanding was come to between Lord R. Cecil, Sir J. B. Tuke, Sir Henry Craik, and Mr. G. J. Cooper, M.R.C.S., on the one hand, and the President of the Local Government Board on the other, that the medical man should be exempted from the compulsory clauses. On this understanding the opposing motions of which Sir J. B. Tuke and Mr. Cooper had given notice were withdrawn. Eventually, however, the Bill passed, apparently because Mr. Cooper expressed his willingness that it should.[1] This preamble is necessary for the understanding of a debate which was held at the meeting of the Chelsea Borough Council on Jan. 22nd as to the question of adoption of the Act. The public health committee reported that it was not satisfied that the Act would prove workable and recommended that the motion to adopt the Act should not be carried. After various speeches, notably one from Dr. L. Parkes, who pointed out that the medical profession was strongly against the provisions of the Act as it stands, the recommendation of the public health committee was carried. We have upon a previous occasion said that we consider the principle of notification to be good and of value to the body politic. But we strongly object to a duty being laid upon medical men to notify, not merely because no fee is provided, for the members of the medical profession are quite accustomed to that treatment from the State, but because a penalty is laid upon them if they do not carry out the provisions of the Act. If one important borough considers that the Act will be unworkable others may do so too, although many have already adopted it. It must be remembered that Clause 3 gives power to the Local Government Board to declare the Act in force in any area in which it might have been adopted, although the local authority has not adopted it.

THE BRITISH SHIP SURGEONS' ASSOCIATION.

ON Monday evening last, Jan. 27th, a meeting of past and present ship surgeons was held at the Medical Graduates' College and Polyclinic, Gower-street, London, for the purpose of discussing the unsatisfactory status and conditions of employment of ship-surgeons and considering the best means of effecting the necessary reform. Mr. G. Metcalfe Sharpe of Middlesmoor, Leeds, was in the chair and it was unanimously decided to form a British Ship Surgeons' Association. A provisional committee, comprising Mr. Sharpe and Mr. H. W. Bayly of 25, New Cavendish-street, London, W., with Mr. J. Arthur Batley, solicitor, of East Parade, Leeds, was appointed to take the necessary preliminary steps. Communications on the subject may be addressed to any of the gentlemen named.

PROFESSOR MARAGLIANO'S ANTI-TUBERCULOUS SERUM.

WE have received a communication from Messrs. Oppenheimer, Son, and Co., Limited, 179, Queen Victoria-street, London, E.C., stating that they have been appointed agents for the "Istituto per lo Studio e la Cura della Tubercolosi e di altre Malattie Infettive" in Genoa. This firm also informs us that the Istituto would be willing to forward a supply of Professor Maragliano's anti-tuberculous serum to any institution especially arranged for the treatment of tuberculosis free of charge so as to enable the medical staff "to confirm the results already obtained." Professor Maragliano's views have for a considerable period been before the profession. In regard to the effect of the anti-tuberculous serum on pulmonary tuberculosis he maintains that complete and permanent arrest can be obtained in cases in which the first and second barriers of organic defence are still intact—that is, in cases in which the pulmonary tissues prevent the extension of the disease from the foci in which it first develops or in those cases in which the lesion is well localised in the lungs and in which toxæmic phenomena have not developed. On the other hand, such successful results cannot be obtained when "inflammatory centres" have been produced. Even in those cases, however, a beneficial influence may be exerted if there is an absence of those local physical phenomena which characterised these lesions. A trial of Professor Maragliano's serum has been made in the Henry Phipps Institute in Philadelphia. Dr. M. P. Ravenel had studied in Professor Maragliano's laboratory for the purpose of learning the methods there adopted, so that he was in a position to make the serum strictly in accordance with the rules and practices of Professor Maragliano himself. The work which was accomplished at the institute with this serum was not encouraging. The conclusion must not be arrived at, however, that it has no value in the treatment of tuberculosis. In the third annual report of the institute it is stated that all that can be said is that it is of no practical value according to the method of using it in that institution. Certain facts, suggestive of good, appeared and indicated better ways of employing the serum. It has been determined that the workers at the institute will continue with the trial of the remedy. We publish the above announcement so that those observers who wish to the prevalence of the disease which may perhaps be looked for as a result of notification, are matters which necessarily depend on the character of the local organisations available. A scheme of voluntary notification has been provided in some towns but in practice, for various reasons, no use is made of it. In other towns, however, such as Manchester, notifications under a voluntary scheme are numerous and this has been markedly the case where very careful and tactful use has been made of the information supplied, where the patient is in no way harassed in a social sense, and where (as in Brighton) something is done as a result of the notification which the patient at once recognises to be to his own interest and advantage. Compulsory notification, under special clauses of local Acts, is operative in only two English towns—Sheffield since 1903 and Bolton since 1902. Dr. BULSTRODE considers that more time and experience are necessary before conclusions can be drawn as to any advantages which compulsory notification may have in affording means by which the prevalence of pulmonary tuberculosis may be reduced. His advice on this as on several other matters may be said to be based on the text, "He that believeth shall not make haste." There will perhaps be critics of his report who consider his pace too slow but all will join in welcoming the substantial contribution to the foundations of belief in regard to the prevention of tuberculosis which this volume affords.

---

[1] THE LANCET, Sept. 7th, 1907, p. 742–743.

Annotations.

"Ne quid nimis."

THE MEDICAL INSPECTION OF SCHOOL CHILDREN.

THE Board of Education, in response, we understand, to requests from local educational authorities, has issued a circular to those bodies containing a schedule for the guidance of medical officers inspecting school children under the new Act; at the same time the Board acknowledges the expediency of leaving considerable latitude in its administration in different cases or circumstances. We are not printing in this issue of THE LANCET the 24 clauses of the schedule and shall withhold any detailed comment upon them until we lay them before our readers. The schedule is framed, as the Board points out, more with a view to administrative than to educational or scientific expediency, many points of anthropometrical and *statistical* interest being purposely omitted, so that it does not profess to be a guide to a full clinical examination of the child. The aim of the Board is to hasten slowly towards a desirable end and not to arouse the prejudices of ignorant parents or to throw too much strain on the coöperation of the educational and public health authorities, which for the first time are working officially together in the public service. It is hoped that by the proper use of this schedule few cases of serious physical defect will escape detection and we think this may be so. The schedule certainly covers the necessary ground but we are inclined to doubt whether the Board is not too sanguine in considering that each child can be examined in accordance with it "in the space of a few minutes." A specimen card accompanies the circular, on the back of which is printed the schedule, as in the circular, with blank spaces to record the results of the examination of a child. On the front of this card the following is printed:—

SCHEDULE OF MEDICAL INSPECTION.

I.—Name ....
Surname first.
Date of Birth ....
Address..
School ....

II.—Personal History:
(*a*) Previous Illnesses of Child (before admission).

Measles....................................	Scarlet Fever....................................
Whooping Cough....................	Diphtheria....................................
Chickenpox....................................	Other Illnesses....................................

(*b*) Family Medical History (if exceptional).

A third of this side of the card is reserved for general observations and directions to parent or teacher. These cards will not be supplied in bulk by the Board but are intended as a model for local authorities which are recommended to obtain similar cards for the systematic record of the physical condition of the children under their charge.

"TUBE FEARS."

THERE can be little doubt that the minds, at all events of some of the public, are uneasy about the safety of travelling on the underground electric trains, but more particularly the "tube" railways. There are not a few people who confess to a nervous feeling when travelling on the "tubes," while others avoid this expeditious method of travelling altogether because they have terrible pictures in their minds of possible disasters in circumstances which admit of no escape. Already some unpleasant incidents have occurred which fortunately have been free from very serious issues; but they have served to indicate to what a terrible position travellers on the underground electric railways may be exposed. According to a Board of Trade inquiry into an outbreak of fire which happened on a train on the Metropolitan District Railway the main danger in cases of fire arises from panic but it is difficult to see how panic in such trying circumstances can be averted. In the case of the Metropolitan and District Railways the chances of escaping from danger are more favourable than they are on "tube" railways, but fires have occurred in the "tubes" also. Imagine a train in the "tube" packed with "strap-hangers," in addition to seat-holders, stopping in a tunnel into which the carriages fit almost with the nicety of a plunger in a syringe, and that owing to a short circuit dense volumes of smoke from the destructive distillation of inflammable materials such as wood and bituminous substances make their appearance to render the atmosphere unbreathable. What adequate means of escape is there having regard to the fact that there are only exits at the ends of the long carriages? Assuming again that these exits are successfully negotiated by hundreds of people, how much better off are they when they have gained a tunnel containing a live rail? We cannot help thinking that the "tube" railway companies should be able absolutely to satisfy the public on these points. If, as the Board of Trade states, the chief danger is that of a panic arising from fire, surely something ought to be done to render an outbreak of fire practically impossible. More than five years ago in these columns we directed attention to the risks of fire on the tube railways and ventured to make a few practical suggestions calculated to minimise the chances, at all events, of an extensive fire occurring. It seems to us that the general use of non-combustible material or material the two preceding weeks; of these, 154 resulted from whooping-cough, 99 from measles, 57 from diphtheria, 39 from scarlet fever, 38 from diarrhœa, 22 from "fever" (principally enteric), but not one from small-pox. The deaths from these epidemic diseases in the 76 towns were equal to an annual rate of 1·3 per 1000, the rate from the same diseases in London being only 1·1. No death from any of these epidemic diseases was registered last week in Brighton, Walthamstow, Stockport, Hornsey, or in five other smaller towns; the annual death-rates from these diseases ranged upwards, however, in the other towns to 2·8 in Ipswich and in Gateshead, 3·0 in Willesden, 3·1 in Salford, and 3·7 in Aston Manor. The fatal cases of whooping-cough in the 76 towns, which had been 92, 127, and 164 in the three preceding weeks, declined last week to 154; the highest annual rates from this disease last week were 1·5 in Handsworth, 1·7 in Newcastle-on-Tyne, 2·2 in Warrington, and 3·7 in Aston Manor. The 99 deaths from measles showed a further decline from the numbers in the two previous weeks; this disease, however, caused a death-rate of 1·3 in Preston and Southampton, 1·4 in Ipswich, 1·7 in Salford, and 2·6 in Willesden. The fatal cases of diphtheria also showed a further decline from recent weekly numbers, but included 22 in London, six in Manchester and Salford, two in South Shields, and three in Gateshead, the latter being equal to an annual rate of 1·2 per 1000. The 38 deaths attributed to diarrhœa showed a marked decline, as did the 39 fatal cases of scarlet fever, which included 19 in London, four in Liverpool, three in Manchester and Salford, and two in West Ham. The 22 deaths referred to "fever" also showed a decline, including four in London and three in Manchester. The number of scarlet fever patients under treatment in the Metropolitan Asylums and London Fever Hospitals, which had steadily declined in the seven preceding weeks from 5581 to 4325, had further fallen to 4044 on Jan. 25th, and during the week ending on that day 380 new cases were admitted to those hospitals, against 469 in each of the two previous weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 333, 460, and 498 in the three preceding weeks, declined again last week to 455, but exceeded by 36 the corrected average number in the corresponding week of the five years 1903–07. The causes of 59, or 1·0 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, and in 48 of the other smaller towns; and the causes of all but one of the 1651 deaths in London were duly certified. No fewer than 13 of the causes of death in Liverpool were, however, uncertified, and 10 uncertified deaths were registered in Birmingham, five in Sheffield, four in Sunderland, and three in Bootle and in St. Helens.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 24·3 per 1000 in each of the two preceding weeks declined to 22·2 in the week ending Jan. 25th, but exceeded by 3·7 the mean rate during the same week in the 76 English towns. Among the eight Scotch towns the death-rates ranged from 17·7 and 17·9 in Edinburgh and Aberdeen, to 25·4 in Glasgow and 26·7 in Perth. The 782 deaths in these eight towns showed a decline of 75 from the number in the previous week, and included 142 which were referred to the principal epidemic diseases, against numbers increasing from 109 to 158 in the four preceding weeks; of these, 81 resulted from measles, 25 from whooping-cough, 16 from diarrhœa, nine from "fever," eight from diphtheria, three from scarlet fever, but not one from small-pox. These 142 deaths were equal to an annual rate of 4·0 per 1000, which exceeded by no less than 2·7 the mean rate last week from the same diseases in the 76 English towns. The fatal cases of measles in the eight Scotch towns, which had been 53, 65, 84, and 92 in the four preceding weeks, declined again to 81 in the week under notice, of which 70 occurred in Glasgow, four in Paisley and in Greenock, and three in Aberdeen. The 25 deaths from whooping-cough also showed a decline from the number in the previous week; seven were, however, returned both in Glasgow and in Leith, four in Perth, and two in Edinburgh and in Aberdeen. Of the 16 deaths attributed to diarrhœa, 11 occurred in Glasgow and two in Edinburgh and in Leith. The nine deaths referred to "fever" included six in Glasgow, two in Edinburgh, and one in Dundee; one of the six fatal cases in Glasgow and those returned in Edinburgh and Dundee were certified as cerebro-spinal meningitis, the remaining five fatal cases in Glasgow being due to enteric fever. Four of the eight deaths from diphtheria and two of the three from scarlet fever were returned in Glasgow. The deaths referred to diseases of the respiratory organs in these eight towns, which had been 205 and 199 in the two preceding weeks, further declined to 178 in the week under notice, but exceeded by 42 the number from the same diseases in the corresponding week of last year. The causes of 22, or 2·8 per cent., of the deaths in these towns last week were not certified or not stated; in the 76 English towns the proportion of these uncertified deaths last week did not exceed 1·0 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 25·5, 26·0, and 31·2 per 1000 in the three preceding weeks, declined again to 29·5 in the week ending Jan. 25th. During the first four weeks of the current quarter the death-rate in the city has averaged 28·1 per 1000; the rate during the same period did not exceed 18·2 in London and 18·1 in Edinburgh. The 223 deaths of Dublin residents registered last week showed a decline of 13 from the high number in the previous week, and included nine which were referred to the principal epidemic diseases, against but four and three in the two preceding weeks; these nine deaths included five from whooping-cough, two from "fever," one from measles, one from diarrhœa, but not one either from scarlet fever, diphtheria, or small-pox. These nine deaths from epidemic diseases were equal to an annual rate of 1·2 per 1000, the death-rate from the same diseases last week being 1·1 in London and 0·9 in Edinburgh. The fatal cases of whooping-cough in Dublin showed an increase upon recent weekly numbers. The 223 deaths in the city last week from all causes included 29 of infants under one year of age and 73 of persons aged upwards of 60 years; the deaths of elderly persons were again exceptionally high. Two inquest cases and two deaths from violence were registered, and 88, or 39·5 per cent., of the deaths occurred in public institutions. The causes of five, or 2·2 per cent., of the deaths in the city last week were not certified; in London all but one of the 1651 deaths were duly certified, while in Edinburgh the causes of 3·4 per cent. of the deaths were uncertified.

"Audi alteram partem."

THE TREATMENT OF PULMONARY TUBERCULOSIS BY GRADUATED LABOUR.

To the Editor of THE LANCET.

SIR,—To one who has devoted much time during the past few years to elaborating methods and teaching the value of graduated work as a therapeutic agent in pulmonary tuberculosis, it is gratifying to learn from Dr. M. S. Paterson's paper in THE LANCET of Jan. 25th, p. 216, that the principle of graduated labour has been adopted, and thanks to his zeal and energy put into effective practice in the sanatorium recently opened in connexion with Brompton Hospital. He is to be congratulated on the efficiency of the simple scheme he has proposed. It is, of course, not necessary, or even desirable, to insist on the particular gradations of carrying, spade-work, and pick-axe. There is great variety possible in the practical application of the principle.

While offering my congratulations to Dr. Paterson on so excellent an illustration of the great principle, I find it less easy to follow him when he speaks of it as a novel idea and cites once more *a priori* objections which from time to time have been urged against it and as often answered. I had supposed that the significance of graduated work in the treatment of pulmonary tuberculosis was now freely admitted by those who had looked into the matter. The principle was colon on the right side near the liver and much pus gushed out." This *may* have been an appendix abscess but he goes on to say that much pus also was evacuated with the urine, so we cannot be sure that it was not a pyonephrosis. Here and there through the following centuries we find cases recorded which are fairly certainly examples of incision of an appendix abscess but it was not till 1759 that we meet with an operation for abscess which was definitely shown to be due to disease of the vermiform appendix; in that year Mestivier incised an abscess on the right side of the abdomen near the umbilicus and much pus was evacuated. The wound healed but the patient died before long and at the necropsy a pin was found in the appendix with many signs of inflammation. Seven years later Lamotte described a large fæcal concretion in the appendix but the discovery was only made post mortem. In 1848 Hancock reported the opening of an abscess immediately above Poupart's ligament on the right side and later two fæcal concretions came away. The incision was made early, even before fluctuation could be detected. In 1867 Parker published four similar cases and from that time the opening of abscesses in the right iliac fossa became less rare. The earliest suggestion to remove the appendix appears to have been made by Fenwick in 1884 and this operation was performed by Krönlein in the same year. He opened the abdomen of a boy aged 17 years who had general peritonitis and ligatured and removed the perforated appendix. Some temporary improvement followed but death occurred three days after the operation. Symonds in 1885 removed a concretion from an appendix without opening the peritoneal cavity. The first successful operation for the removal of the appendix was performed by Morton in 1887 and from that time the operation has become common. We have then answered the question, "When was the first operation for appendicitis performed?" by showing that appendix abscesses have been *opened many* centuries ago; that Hancock in 1848 incised an appendix abscess before fluctuation could be felt; that Krönlein in 1884 removed a perforated appendix but the patient died; and that Morton in 1887 had the first successful case of appendicectomy.

THE METROPOLITAN WATER-SUPPLY.

THE report on the condition of the metropolitan water-supply for last October shows that the rainfall in that month was 2·70 inches above the average mean rainfall of 24 Octobers. It will be remembered that September was an exceptionally dry month and in consequence the October rains were not able to bring the daily natural flow of the Thames up to its 24 years' average, but they caused the usual turbidity of the water and from the 17th to the 24th it was more or less coloured in consequence. On the remaining days it was clear and in good condition. The filtered water from the various works contained less organic matter than in any preceding month last year except that from the West Middlesex works which contained the same quantity as in September. The Lea water is reported as of very good quality throughout the month, and the Kentish chalk wells were as satisfactory as usual. All the samples of water collected from public taps and examined were free from any appreciable quantity of suspended matter. By the colour *test* the Lambeth water, as usual, showed the deepest average tint of brown, but *per contra* it contained the lowest average of microbes—viz., 3·8 per cubic centimetre. The worst offender in this respect was the sample from the Grand Junction division of the southern district which showed the large number of 4625·1 per cubic centimetre. We need hardly say that this is most unsatisfactory and it is liable to recur whenever the condition of the Thames is unfavourable or when an unusual strain is thrown on to the filter beds at Kew Bridge, which for lack of accommodation for storage and settlement are obliged to treat a large proportion of their water in a practically raw condition. A marked improvement has taken place in the Southwark and Vauxhall water since the Hampton reservoirs were brought into use and it is urgent that a similar measure should be adopted at Kew. The bacillus coli was found in 10·7 per cent. of the filtered samples of Thames water, 100 cubic centimetres of each being examined. It was found in 8·7 per cent. of similar samples of Lea water and 13·7 per cent. of similar samples of New River water respectively. Although the London water-supply has improved materially of late years it is obvious that there is still room for much more improvement, especially in this bacteriological respect.

THE MODE OF TRANSMISSION OF TRYPANOSOMES BY TSETSE FLIES.

A RECENTLY published Parliamentary paper, headed "Miscellaneous No. 6 (1907)," contains a report prepared by Dr. Louis W. Sambon, the Italian delegate to the International Congress on the Sleeping Sickness held at London in June, 1907. The report is written in French but an English translation is appended, and there is a note explaining that the time and labour necessary for its preparation made it impossible for it to be included in the published proceedings of that conference. The subject of the report is the mode of transmission of sleeping sickness. Dr. Sambon criticises the views expressed by Colonel David Bruce, R.A.M.C., and Professor Minchin, and while he admits that it is possible that both nagana and sleeping sickness may be transmitted by tsetse flies in a purely mechanical way he is convinced that under natural conditions this is not the usual mode. He maintains that in each case the fly acts as a true alternative host and that the respective parasites go through a peculiar cycle of development and multiplication within the body of the insect before they are returned to fresh vertebrate hosts. He criticises the experiments described by Colonel Bruce and other observers in support of the "mechanical" theory, which is in brief that the infection of the disease is conveyed by the proboscis of the tsetse fly in much the same manner that the vaccinating needle carries the infection of vaccinia from child to child. The general principle of these experiments is that of allowing tsetse flies to feed upon an infected animal and subsequently upon a normal one. One of the chief objections which he raises is that in these experiments the tsetse flies used have been caught in infected localities and may therefore have harboured trypanosomes in their salivary secretion at the time when they were caught. He also objects that if the mode of transmission of trypanosoma Gambiense or trypanosoma Brucei is purely mechanical it is difficult to understand why the diseases caused by these two parasites should be so strictly confined to the localities where certain species of the tsetse fly are found and why other blood-sucking diptera should not be able to carry them and to infect animals in the same mechanical manner. He further claims as strong presumptive evidence in favour of some further development of the parasites in their invertebrate hosts, the fact that trypanosomes taken from the gut of the tsetse fly and injected into vertebrates do not produce the disease, although they are living, the suggestion being that they belong to a sporogonic cycle in the life of the trypanosome incapable of multiplication in the blood of a vertebrate host. Unlike the diptera of the families culicidæ, simulidæ, and tabanidæ, in which the females alone are blood-suckers, in the glossinæ both sexes have this property, and Dr. Sambon suggests that it is possible that the further growth of the trypanosome in the fly may only be capable of occurring in the female; he therefore suggests that in future experiments the sex of the flies used shall be carefully determined and recorded. He affirms extremely emaciated, weighing less than 4 stones; pulse-rate usually about 160; temperature pyrexial; mental condition one of delirium at night and obfuscation during the day; and all the usual symptoms of the most severe type of Graves's disease were present. Although under good conditions at her home she had been steadily getting worse and had been altogether confined to bed for several weeks. I had every reason to consider the prognosis as extremely grave indeed. I have not hitherto seen a case of Graves's disease in that stage end otherwise than fatally. I ordered her to have an ounce of rodagen daily. The improvement of her condition which soon took place was most striking. The acute symptoms all subsided, her mind became clear, her temperature dropped to normal, the heart's action considerably slowed down, the tremors ceased, and in a few weeks she gained a stone in weight. In spite of the fact that her recovery has been interrupted by one attack of influenza and another of quinsy she has done remarkably well.

If I had the choice of giving rodagen or the fresh milk of a thyroidectomised goat I should not hesitate to select the latter from which rodagen is derived. But I consider it is a great matter that it is possible to prepare from the milk a substance like rodagen which possesses similar beneficial properties to those of the milk itself. Rodagen is readily obtainable at a price, but the fresh milk of a thyroidectomised goat is not to be had by most of our patients for either love or money. The main drawback, indeed, to rodagen is the usual disproportion between its cost and the purse of our patient. It is one of those remedies which, as I have said before, few except hospital patients can afford to use. It is its high price which makes us inclined to dole it out even to our hospital patients when we should otherwise give it freely. Wholesale it at present costs between 3*s.* and 4*s.* an ounce. The only other drawbacks are its somewhat unpleasant cheesy smell and taste and an occasional tendency to purgative action. But some might raise the same objection to the use of goat's milk.

I may say I have not given more than an ounce a day in any case, but I believe smaller doses than this are not of much use in the presence of severe symptoms. I have previously stated that although I have made an extensive trial of Merck's antithyroid serum, which is prepared from thyroidless rams, I was not convinced that it exerted any beneficial influence. It is quite possible that if I had tried it in larger doses than I did I might have obtained some good results. All I can say about it is that in the doses ordinarily prescribed it seemed to me inert. I did not go beyond a dose of five cubic centimetres daily. This remedy is also expensive, ten cubic centimetres costing about 5*s.*

I should like to add to what I have said about rodagen that in cases of Graves's disease lately I have not been giving ordinary milk except in such small quantities as are usually taken with tea or coffee. If, as present observations indicate, there be a virtue in the milk of a thyroidless animal, and in the rodagen obtained from it, by means of which the toxin of Graves's disease is neutralised, this is likely to be counteracted if at the same time we gave in any considerable quantity the milk of an animal whose thyroid was in full functional activity. Recently I have been allowing not only little milk but also little meat to my patients with active Graves's disease and I believe this has been of benefit to them. In conclusion I should like to suggest that it might be possible to put up in tins condensed milk made from the milk of thyroidectomised goats, but I am afraid the remedy, however prepared, will continue to be expensive.—I am, Sir, yours faithfully,

HECTOR MACKENZIE, M.D. Cantab.,
Physician to St. Thomas's Hospital.
Jan. 27th, 1908.

LIQUID AIR AND CANCER.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Jan. 25th Professor J. E. Salvin-Moore and Mr. C. E. Walker relate some observations they have made on the effect of exposing the cells of a carcinoma to the temperature of liquid air for 20 to 30 minutes. In the same issue the importance of these observations is emphasised by a second communication, in which they are confirmed by Professor Salvin-Moore and Dr. J. O. Wakelin Barratt for another carcinoma. The authors express surprise that the substance of tumours so treated gave rise to growths when implanted into healthy animals. The conclusion that the proliferation of the parenchyma cells implanted is responsible for the parenchyma of the daughter tumours would seem, in the opinion of the authors, to be laid open to doubt as the result of their application of what, in the absence of any reference to the literature on the subject, has the semblance of an experimental method new in cancer research.

That cancer cells may retain their vitality after long exposure to low temperatures has long formed part of the common stock of knowledge of those engaged in experimental cancer research. Two years ago Ehrlich obtained continued growth after an exposure to −10° C. lasting two years, and also after an exposure to the temperature of liquid air 144 times as long as that employed by the authors of the two communications referred to. Michaelis has obtained continued growth after the cells had been exposed to the temperature of liquid air for half an hour three years before the repetition of a similar experiment has yielded a result so surprising to Professor Salvin-Moore and his two colleagues.

There are many other references to the effects of thermal agencies in the literature of experimental cancer research, to which I need not refer in detail, since the two authors cited dealt specifically with the temperature of liquid air, and support the views advanced by Jensen, Murray, and myself on the processes at the site of the implantation of cancerous tissue. It will suffice to point out that exposure to thermal agencies is a routine laboratory method used to diminish the vitality of the cells of malignant new growths, and that with the extinction of the life of the cancer cells inoculation ceases to be successful. Although exposure to thermal agencies is a valuable method for studying the *vita propria* of the cancer cell, it is, for the reason just stated, unsuited to settle whether or not there be a virus in the tumour substance. The results of the cytological study of the site of inoculation in conjunction with this method have been found to be in entire agreement with the view that the artificial propagation of cancer is an actual transplantation of living cells which are merely nourished by a succession of new hosts.

I am, Sir, yours faithfully,
Jan. 27th, 1908. E. F. BASHFORD.

SUFFOCATION BY COMPRESSION OF THE CHEST: THE BARNSLEY DISASTER.

To the Editor of THE LANCET.

SIR,—The sad accident at Barnsley whereby some 16 children lost their lives presents some features in common with the one at Sunderland in 1883 when nearly 200 lost their lives. In the present instance a large number of children were endeavouring to force their way into the gallery of the public hall to witness a cinematographic entertainment. On the gallery being completely filled the children on the stairs were turned back by the attendant and told to make their way to other parts of the house. A stampede then occurred on the staircase, several of the little ones fell at a turn in the stairs and others fell upon them, the whole being kept from regaining their footing by the pressure of the children behind. Before they could be extricated 14 children of an average age of six years lost their lives and two more died very shortly afterwards in hospital. Those who recovered seemed to have sustained surprisingly little injury. Out of the 16 killed and 17 slightly injured, attended to at the Beckett Hospital, only one sustained a fracture—viz., a fractured humerus. This, of course, may be accounted for by the greater flexibility of children's bones, especially the ribs. The children seen immediately after death presented practically the same features as described by Dr. Lambert in 1883 in his report on the disaster at Sunderland.[1] In varying degree their faces were congested and puffy, the vessels of the neck much swollen, the eyelids closed, the eyeballs protruding, the pupils widely dilated, and froth surrounding the mouth and nostrils. In nearly all the cases urine had been voided and in a few cases fæces expelled.

By order of the coroner a careful and individual examination of the whole of the bodies was made 24 hours after death and in the case of two bodies post-mortem examinations were made by Dr. Hall and Mr. V. K. Blackburn. The external examination presented the following features. Rigor mortis (probably influenced by the cold) and post-mortem staining were well marked in all cases. With one or two exceptions the countenance was placid as if in sleep, the eyeballs were not protruding nor the pupils widely dilated. In three cases the face was markedly congested, the remainder varying from slight frontal suffusion to slight general congestion. The ears in all cases were much darker test the true value of the serum may be able to obtain a supply.

---

[1] Brit. Med. Jour., vol. i., 1883.

A TELEGRAM from the Acting Governor of the Gold Coast received at the Colonial Office on Jan. 22nd states that on that date there were 2 deaths from plague. The number of natives in hospital was 16, and 51 were isolated. A further telegram received on Jan. 24th states that on Jan. 23rd the number of deaths was 4, number of natives in hospital 18, and isolated 58. Another received on Jan. 27th states that on Jan. 26th the number of deaths was 1, number of natives in hospital 10, and isolated 30.

THE Lettsomian lectures for 1908 on "Tuberculosis of the Lung" and "Malignant Diseases of the Cæcum" will be delivered by Mr. Charters J. Symonds at the Medical Society of London, 11, Chandos-street, Cavendish-square, London, W., on Feb. 3rd and 17th, at 9 P.M., and March 2nd, at 9 P.M. The lectures will be illustrated by lantern slides, cases, and specimens.

AT the last meeting of the council of the National Association for the Prevention of Consumption and other Forms of Tuberculosis, Professor William Osler, Regius professor of medicine of the University of Oxford, and Dr. Arthur Latham, physician to St. George's Hospital, were elected to the council.

BRITISH MEDICAL BENEVOLENT FUND.

AT the January meeting of the committee 12 applications for help were received and grants amounting to £102 made to nine of the cases. It was decided to hold the annual general meeting of subscribers at 5 30 P.M. on Tuesday, Feb. 18th, at 15, Wimpole-street, W. Appended is an abstract of the cases relieved.

M.B., C.M. Aberd., aged 69 years. Earnings always small and is now practically incapacitated. Has only a few shillings a week. Recommended by Professor J. G. McKendrick. Voted £12.

Daughter, aged 54 years, of late M.R.C.S. Has supported herself by taking private pupils, but lost them all during the past year owing to her mother's prolonged illness ending in death. No income. Recommended by Mr. William Rhodes. Voted £10.

Daughter, aged 60 years, of late M.R.C.S. Supported herself by teaching for many years but has now lost her sight and subsists on a few shillings a week allowed by a charitable institution. Relieved three times, £22. Recommended by Mr. T. A. Osborn, honorary local secretary, and Mr. Ashby G. Osborn. Voted £10.

Widow, aged 56 years, of L.R.C.P. Edin. No income, lets lodgings. Relieved five times, £50. Recommended by Dr. Robert Blair. Voted £12.

Widow, aged 54 years, of L.R.C.P., L.R.C.S. Dub. No income. Right hand permanently injured; children unable to help. Relieved three times, £29. Recommended by Dr. C. W. Buckley. Voted £12.

Daughter, aged 55 years, of late M.R.C.S., L.S.A. Has maintained herself as matron in a school for several years but was obliged to give up the post to nurse an invalid mother, since dead. At present has obtained no other appointment. Relieved once, £12. Recommended by Dr. C. J. Gibb. Voted £12.

Widow, aged 50 years, of M.R.C.S., L.S.A. No income; a little help from a relation. One child still dependent and the rest barely self-supporting. Relieved 12 times, £133. Recommended by Dr. Charles Steele. Voted £12.

Daughter, aged 70 years, of late M.R.C.S., L.S.A. Only income £20 a year and occasionally earns a few shillings by needlework. Relieved eight times, £33. Recommended by Mr. George Eastes. Voted £12.

Widow, aged 49 years, of L.R.C.P., L.R.C.S. Has endeavoured to support herself by letting lodgings, but is now obliged to give up on account of ill-health and has had to sell her furniture to pay some small debts. Children unable to help. Relieved three times, £48. Recommended by Dr. William Carter. Voted £10.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: J. J. Walsh to the *Bacchante* and C. Strickland to the *Cochrane*, both on recommissioning; C. M. Beadnell to the *King Alfred*; and J. D. Hughes to the *Donegal*. Staff Surgeons: H. B. Hall to the *Europa*, on recommissioning; and J. C. Rowan to the *Sapphire*, additional, for the *Tyne*. Surgeons: J. C. Bringan to the *Bacchante* and D. D. Turner to the *Cochrane* both on recommissioning; A. R. Schofield to the *Victory*; G. L. Buckeridge to Portland Hospital; T. D. Liddle to the *New Zealand*; E. F. Ellis to the *Argyll*, on recommissioning; and H. B. German to the *Terrible*.

ROYAL ARMY MEDICAL CORPS.

Lieutenant Alan C. Vidal is placed temporarily on the half-pay list on account of ill-health (dated Jan. 12th, 1908).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Newcastle-on-Tyne: Surgeon-Captain J. D. Farquharson to be Surgeon-Major (dated Dec. 25th, 1907).

Rifle: 2nd Volunteer Battalion, The Norfolk Regiment: Surgeon-Captain S. J. J. Kirby to be Surgeon-Major (dated Dec. 4th, 1907).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

East Surrey Bearer Company: Lieutenant-Colonel John J. de Zouche Marshall has been promoted to Brigade-Surgeon-Lieutenant-Colonel and appointed as Senior Medical Officer of East Surrey Volunteer Infantry Brigade (dated Nov. 27th, 1907).

THE AUSTRALIAN ARMY MEDICAL CORPS RESERVE.

The *Australasian Medical Gazette* of Dec. 20th, 1907, states that "the Australian Army Medical Corps Reserve is to be a special volunteer force. The officers are to be drawn from the registered medical practitioners, in addition to those now on the list, which latter number 25 for the whole Commonwealth. They will be graded into consultative and executive staffs, and will form the medical and surgical staffs for the Government civil hospitals, where the sick and wounded might be taken, and be a staff for duty in the field or in garrison. Students of medicine will be drawn upon for other ranks, and also dentists, chemists' assistants, members of recognised ambulance societies, and special trades. Schools of instruction will be opened to members of corps, with a provision that no extra expense is to fall on the Government on account of them."

VITAL STATISTICS.

VITAL STATISTICS FOR 1907.

THE following are the provisional figures showing the vital statistics of England and Wales for the year 1907. Their early appearance reflects great credit on the Registrar-General's Department:—

—	Annual rate per 1000 living.			Deaths under 1 year per 1000 births.
	Births.	Deaths.	Principal epidemic diseases.	
England and Wales	26·3	15·0	1·26	118
76 great towns	27·0	15·4	1·54	127
142 smaller towns	25·7	14·5	1·29	122
England and Wales, less the 218 towns...	25·6	14·7	0·91	106

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8558 births and 5749 deaths were registered during the week ending Jan. 25th. The mean annual rate of mortality in these towns, which had been equal to 16·9, 19·3, and 20·0 per 1000 in the three preceding weeks, declined again to 18·5 in the week under notice. During the first four weeks of the current quarter the annual death-rate in these towns averaged 18·7 per 1000; the rate during the same period in London did not exceed 18·2. The lowest annual death-rates in the 76 towns last week were 7·3 in Hornsey, 9·8 in East Ham, 9·9 in Smethwick, and 10·7 in Walthamstow; the rates in the other towns ranged upwards to 26·0 in Plymouth, 28·3 in Swansea, 30·6 in Bootle, and 34·3 in Liverpool. The rate in London last week did not exceed 18·0. The 5749 deaths registered in the 76 towns during the week under notice showed a decline of 478 from the number in the previous week, and included 409 which were referred to the principal epidemic diseases, against 457 and 501 in were first systematically made it was found that 42 per cent. of the applicants at the hospitals were ineligible, while now only 4 per cent. are rejected. This shows what strict inquiry will do and how it will keep away those who could pay for medical attendance. But while the lay managing committees of the different Liverpool medical charities might come to a common agreement on this point and also in regard to the overlapping of the various charities, there are other matters on which disagreement is more than probable. Perhaps the most difficult of these is the admission of paying patients into some of the hospitals. Then, even if the lay committees did agree on this grave question, it is very likely that the medical staffs would not take the same view of the subject. In the meanwhile, I found a disposition to make a mystery of their proceedings, and it seemed to me as if the lay committees viewed the prospect of criticism with some apprehension. It appears to me, however, that if the medical profession were united in a strong, compact body the lay committees of the hospitals would be less prone to hold private consultations. They would proceed to the headquarters of the profession and there discuss with those who do the principal work at the hospitals how the various difficulties of management could best be overcome.

Unfortunately, instead of harmony and coöperation between the lay managing committees and the medical staffs of the hospitals some serious disputes may arise. This is the likely consequence of the radical change which new customs and new laws are bringing about. Hospitals are no longer what they used to be. What might be quite right and proper 50 years ago no longer applies to present conditions. There is a tendency to make workmen more and more responsible for their ordinary ailments now that they have compensation. On the other hand, there is such increase in the major surgical operations performed in a hospital that there is less and less room remaining for minor cases such as, for instance, simple fractures. It is true that some general practitioners may prefer to send a case of fracture to a hospital rather than to run the risk of an action for damages should anything go wrong. Still the compensation to which all classes of workers are now entitled should give the general practitioner a better chance. However this may be, the argument now brought forward is that the honorary staffs of hospitals undertook to attend the sick poor and not insured servants and workmen. The question as to what the insurance offices are going to do becomes very important. Are they entitled to send persons for whom they are responsible to hospitals? If the insurance company receives the premium then it ought to pay for the patient. At Hamburg ladies in good positions voluntarily pay 1*s.* per month to the hospitals so as to have the right to send their servants there should they fall ill. Are the insurance companies in England contemplating some similar course. But, if so, it changes entirely the character of the hospitals and the hospital patients; and in that case what corresponding change should be effected in regard to the medical and surgical staffs of the hospitals.

In Liverpool the hospitals have on their committees of management the same men who manage the great ocean liners. These men have wide business experience and great organising capacities. On the whole, also, they pull together fairly well. By their side and on these committees of management sit the elected representatives of the workmen's Saturday hospital fund. The workman who pays regularly 1*d.* a week for the hospitals thinks that he is insured. He therefore goes to the hospital not as an applicant for charity but to claim that for which he has paid. Then, again, at the Stanley Hospital, for instance, patients who live outside the Liverpool radius are taken in at a charge of 10*s.* per week. Many come from Wales or the Isle of Man and the excuse made is that some of these cases are useful for teaching purposes. This, however, may overcrowd the hospital and keep local and really poor patients out. Therefore some of the hospitals will not make any such charge and on this a serious difference of opinion exists between the lay managing committees of the different Liverpool hospitals. The Royal Infirmary in six months admitted 345 patients from outside the Liverpool radius. Then there are a number of patients who are not poor patients but pay £2 2*s.* a week for their treatment and this brought in the goodly sum of £13,270 in 1905. Such payments seem to be increasing.

In the face of all these new facts the honorary staffs of the various hospitals are striving to form an association so as to take united action and to demand a *quid pro quo.* If the hospitals remain pure charities they have nothing to say; but if hospitals, managed by eminent business men, are to be made paying business concerns, the honorary medical staffs will claim their share in the profits. As for the honorary staffs obtaining indirect advantage this is not always the case; besides, the field for private practice is being gradually restricted as well-to-do people go more and more frequently to the paying wards of the hospitals. The unfairness of the present situation is admirably illustrated in regard to the building of the Manchester Ship Canal. On that occasion a staff of medical men were employed and paid. They followed the works and attended to all cases of accidents, &c. But to-day there is the Mersey Dock and Harbour Board which employs at the Liverpool docks a large amount of labour. When an accident happens the victim is sent to the nearest hospital and no payment is made. The case is attended by the medical staff of the hospital but the medical profession receives nothing at all. If the medical profession was paid when an accident occurred at the works of the Manchester Ship Canal why should it not be paid when an accident occurs in the Liverpool Docks? The only reason is a topographical reason. There was no hospital near enough to the Ship Canal.

Another argument was brought forward by several medical men and seemed to weigh heavily in their minds. They thought that as people were made to insure their servants they would subscribe less or not at all to the hospitals. Then again, there was an impression that the very wealthy, the multi-millionaires, had ceased to give to hospitals. These institutions the millionaires argued should be supported by the community, and they preferred to give their money for special chemical or biological research in which the general public took less interest. Thus if the wealthy no longer give so much to the hospitals, if an ever-increasing number of people enter the hospitals as paying patients, and if the treatment of working people and servants is covered by a general system of insurance, the whole basis is changing. The hospitals may cease to be medical charities and become business concerns. Then the incomes of the hospitals being in a large measure derived from the patients, a portion of this income should be devoted to the payment of their medical attendants. As for medical schools, there still remain the workhouse infirmaries which have not been utilised. Indeed, it is a question whether these infirmaries should not be entirely detached from the workhouses. Under the Poor-law people who go to the workhouse infirmary are, if possible, made to pay, but if they pay why should they be treated as paupers. The true pauper is sometimes to be found in the hospital. Such considerations led up, in more than one conversation, to the suggestion that if the hospitals were not ultimately converted into municipal institutions they should at least be rate-aided. One leading member of a hospital staff declared that out of about 800,000 people living at Liverpool some 700,000 did not give anything whatsoever towards the hospitals. Why should a small minority have to bear the burden, and why should the medical men work for nothing? Through the rate everyone might be made to contribute and there would then be money enough to pay the medical staff. As compared with other countries the State in England gives very little for the benefit of science; all the more reason, therefore, for the corporations to act, and they can reach those who do not give voluntarily. Actually the municipality of Liverpool does subsidise the University of Liverpool and this to the extent of £10,000 a year.

The question of the municipalisation of hospitals has lately received more attention from members of the medical profession. In 1896, when I made extensive inquiries at Liverpool, the subject was barely mentioned[1]; to-day I found it a matter of very general discussion. Yet, on the other hand, the growth of insurance does not necessarily make for municipalisation, unless it be in the sense of abolishing hospitals as charities and converting them into paying concerns, each patient paying because he is insured. Then the workhouse infirmaries, which are already municipal hospitals, would be the only hospitals remaining where the patients did not pay. From such conversations it would seem as if the days of charity are numbered and voluntary subscriptions destined to be replaced by compulsory insurance or compulsory taxation, or more probably a mixture advocated, admittedly in less detailed fashion, almost 70 years ago by Dr. Bodington. Indeed, the very title of his essay suggests his view—namely, "An Essay on the Treatment and Cure of Pulmonary Consumption on Principles Natural, Rational, and Successful: with *Suggestions for an Improved Plan of Treatment of the Disease among the Lower Classes of Society*."[1] In the text of the essay Dr. Bodington dwells on the significance of exercise of various kinds, more especially "walking, as much as the strength will allow, *gradually*[1] increasing the length of the walk, until it can be maintained easily for several hours every day." In his extraordinarily clear prevision of the need for sanatoriums, Dr. Bodington goes on to speak of the need for "country houses in proper situations, well ventilated, and provided 'with all appliances and means to boot,' where patients should be strictly watched and regulated in all respects as regards exercise, air, diet, &c." More particularly "with respect to the consumptive poor patients, those who cannot afford to pay for a proper treatment of this sort," he goes on to say, "hospitals should be established in the vicinity of large towns, in fit situations, and properly appointed in all respects for their reception and treatment. In those there should be provision made for ...... gardening, and farming occupations for the convalescent. The common hospital in a large town is the most unfit place imaginable for consumptive patients and the treatment generally employed there very inefficient, arising from the inadequacy of the means at command. ...... Connected with such an hospital provision should be made for the employment of the convalescent and cured patients." In later times Brehmer advocated consistently the significance of graduated walking exercise. This has been continued by many of his disciples.

---

[1] See articles on Hospital Abuse in The Lancet of Nov. 14th (p. 1421) and 21st (p. 1494), and Dec. 12th (p. 1720), 1896.

Personally, I have long held and taught the view that carefully graduated activity in some form is a therapeutic agent of first importance in relation to pulmonary tuberculosis. In seeking to elaborate means of treatment for the poorer classes I have always dwelt much on the significance of *directed activity*. The great plea for such directed effort or labour is to be found in its economic value both to the individual as a preparation for future work after discharge and to the institution in which he is presently resident and to the maintenance of which he is thus enabled to contribute what he can. The significance of graduated labour, both therapeutically and economically, in relation to tuberculosis among the poorer classes, as based on prolonged experience, has formed part of one's regular teaching to students for a good many years. The senior students in the medical school are frequently invited to come and judge for themselves of the beneficial effects of the system. The method has been carried out in more or less elaborate fashion in different institutions elsewhere. I sincerely hope that the object-lesson which Dr. Paterson's paper affords may be the means of still further extending its application. At the Royal Victoria Hospital for Consumpton in the neighbourhood of this city it is routine practice to consider the case of every patient within a month or so after admission, or at least so soon as the temperature record has been approximately normal for a week or two. The patient is first of all tested with simple graduated exercise. Shortly thereafter this takes the form of definite work. The kind of work and its amount is determined exactly in the same way as is other therapeutic procedure. My constant injunction both to assistants and students is that it must be selected and measured just like any drug. An accurate record of its effects is kept from day to day. The results of increase in work are scrutinised as carefully as those from any modification of drug treatment. The amount is increased or diminished as the temperature-chart, pulse-rate, and other indications may suggest. Thus, at the present time out of some 80 patients approximately two-thirds are engaged in such graduated labour. Some of them work a couple of hours a day, others four, others six, others for the whole day, as joiners, engineers, gardeners, painters, wood-cutters, cleaners, inspectors of shelters, &c. We have a considerable collection of photographs illustrative of the kinds of work. Indeed, the annual report of the hospital for several years has contained illustrations showing the patients at work.

I mention these facts to show that the method of treatment need in no sense be spoken of as an experimental one. It has already been amply tested. I venture to say that no one who has made sound and prolonged trial of it has failed to obtain good result. Like every other therapeutic measure it requires thought and care in the selection and adjustment of the particular work. Each case must be judged *per se* and the work strictly accommodated, both in respect of nature and amount, to the possibilities, psychical as well as physical, of the individual. It would be the greatest mistake in the world were the method to become rule-of-thumb and cease to be regulated by consideration of the individual. This is perhaps a danger which is more apt to occur when patients are grouped in squads, the work of the squad being seriously disturbed by failure on the part of any one. There is always some risk of over-effort on the part of a physically weak, though perhaps willing, patient. The danger is, of course, largely obviated if medical surveillance be carried out in the exact and efficient way which has been recommended. Speaking of psychical conditions, it is quite remarkable how quickly improvement may be noted in the spirit as well as in the muscle of the patient after the adoption of *productive* forms of graduated activity, where the patient is able to appreciate and enjoy the result of his effort.

As to the other aspect of the question—namely, the explanation of the effect produced by graduated exercise—I am tempted to write at some length. This would exceed the limits of your correspondence column. I must therefore defer this for the present. Prolonged observation renders me doubtful regarding the suggestion that the benefit of gradually increased physical effort results entirely, or even in largest part, from repeated auto-inoculation. The theory is interesting and attractive. Although a firm believer in the value on the one hand of physical activity, and on the other hand of the direct application of tuberculin in suitable cases, the facts at my disposal make me sceptical as to the validity of the explanation which has been suggested of the indubitable benefit conferred on convalescent patients by a carefully supervised system of graduated labour.

I am, Sir, yours faithfully,

Edinburgh, Jan. 25th, 1908. R. W. PHILIP.

THE TREATMENT OF GRAVES'S DISEASE.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Jan. 25th Mr. Walter Edmunds has recorded three cases of Graves's disease treated with the milk of thyroidless goats. As nearly nine years have elapsed since Lanz first treated cases of this disease by this method and recorded benefit resulting therefrom, I presume it is because of the inherent difficulties in carrying out the treatment that it has not been more extensively employed. The obstacles at any rate have been sufficient to prevent my giving the method a trial myself, anxious enough as I have been to put it to the test. Mr. Edmunds is to be congratulated on having himself successfully surmounted the difficulties and in thus obtaining a sufficient supply of the milk for some of his patients. I trust that his example will be followed by others.

For the encouragement of those who cannot obtain the fresh milk I may say that I believe that the same good effects as are produced by the milk are to be obtained by the use of rodagen. Rodagen, as is now well known, is a substance prepared from the milk of thyroidectomised goats by a process elaborated by Dr. Burghardt and Dr. Blumenthal. It is described as containing 50 per cent of the active constituent of the milk with 50 per cent. of sugar of milk added to preserve it. Although Mr. Edmunds says of two of his patients who were benefited by the milk that previously they had taken rodagen for several weeks without benefit, it is perhaps hardly fair to compare the effect of two drachms per diem of rodagen with that of a pint and a half of the special milk. It is quite possible that if Mr. Edmunds had given larger doses of rodagen he would have been able to observe real improvement under its use such as followed the milk treatment. I have used rodagen very largely in the treatment of Graves's disease and my belief is that if good results are to be obtained from it, it must be given in considerably larger doses than are generally thought to be necessary and than I myself gave at one time. The dose indeed, I think, has to be greater the more severe the symptoms.

I have at the present time under my care at St. Thomas's Hospital a patient who is a very striking illustration of the value of rodagen in the treatment of severe cases. The patient was admitted in a condition of great prostration;

The Purification of Sewage.

For some time past the sanitary authorities of the large towns have been seeking for some simple and rapid method of sewage disposal and the ordinary sewage farms have been a great disappointment to their upholders. They have not been able to treat more than from 10 to 15 litres per square metre per diem. Coke filter beds, which are more active, can only deal with, and that very imperfectly, from 500 to 1000 litres. At a meeting of the Academy of Sciences held on Jan. 12th M. Muntz gave a very interesting account of some work which he had carried out in collaboration with M. Lainé in connexion with the method of purification by peat. A layer of peat, 1·6 metres thick, will deal with 4 cubic metres of sewage per square metre. The pathogenic bacteria are destroyed by nitrifying organisms and the number of organisms in a sample of sewage which before treatment was 3,000,000 is reduced after treatment to 300. Peat purification, besides being a valuable source of nitrogen, answers all the required provisions. There is reason to believe that it will very shortly be applied for the use of the large towns.

Absorption of the Upper Jaw in a Case of Syphilitic Tabes.

At a meeting of the Hospitals Medical Society held on Jan. 10th M. Danlos showed a long-standing case of syphilitic tabes complicated with perforating ulcer of the foot, in which some months ago all the teeth of the upper jaw had fallen out. Shortly afterwards the whole of the right side of the superior maxilla became absorbed and an ulceration appeared at the border of the gum; on the left side a spreading mass appeared which looked exactly like an epithelioma.

The Strike of Medical Men.

In a recent letter[1] I mentioned that the medical men of the department of the Somme had struck against some new regulations of the Assistance Publique. Under the auspices of the Syndicate of Medical Men of the department a meeting was held at the Hôtel de Ville of Amiens and it was decided to take no official part in the working of the Assistance in so far as regards medical practice after Jan. 1st, although it was agreed to attend the poor unofficially up to May 1st. The members of the committee of the Syndicate are now to be prosecuted for putting obstacles in the way of a department for public service.

(FROM OUR OWN CORRESPONDENT.)

Statistics of the Medical Profession in Germany.

ACCORDING to the Medical Directory of the German Empire (Reichsmedizinal-kalender), edited by Professor Julius Schwalbe and summarised in the *Deutsche Medizinische Wochenschrift* by Dr. Prinzing, the number of medical men in Germany at the end of the year 1907 was 31,416, showing an increase of 485 as compared with the previous year. This comparatively slight increase will apparently be soon converted into a large increase, because the number of medical students, which declined sharply some years ago, once more begins to rise. In the summer session of 1905 there were 6032 matriculated medical students, but the corresponding figures for the same period in 1907 were 7574, being an increase of 1500 within two years. It is obvious, therefore, that in four or five years, when these young men become qualified and engage in practice, the profession will again be overcrowded. Of the total number of medical men 18,985 resided in Prussia, 3459 in Bavaria, 2293 in Saxony, 1050 in Würtemberg, 1253 in Baden, 900 in Alsace-Lorraine, 692 in Hamburg, and the remainder in the smaller States of the Empire. It is interesting to learn from the statistical tables that in the great towns of more than 100,000 inhabitants there are 10 medical men per 10,000 inhabitants, 9·1 per 10,000 in towns having from 50,000 to 100,000 inhabitants, 7·0 per 10,000 in towns having from 10,000 to 50,000 inhabitants, and 2·9 per 10,000 in towns and villages having fewer than 10,000 inhabitants. The distribution of the profession throughout the Empire shows considerable inequalities and some curious instances of a deficiency of medical help are mentioned. For instance, the town of Bogetschütz in Upper Silesia, with a population of 19,942, has only one medical man, and this record number is nearly reached by Biskupitz in the same district with one medical man for 12,477 inhabitants. In Westphalia also there are two places of more than 12,000 inhabitants each with one medical man only. Other places with 14,000 and 13,000 inhabitants in Saxony have two medical men, and so on. All these places are situated in the mining districts where the population is comparatively poor. Most of the inhabitants belong to sick clubs and are at work away from home all day long, but nevertheless it is scarcely comprehensible how one medical man can suffice for nearly 20,000 people. On the other hand, Wiesbaden has 25·4 medical men per 10,000 inhabitants, Munich has 15·9, Strasburg has 14·2, Frankfort has 12·1, and Berlin has 11·4. It is noteworthy that specialists are assuming a position of growing importance within the profession as in 1906 there were in the whole Empire 6259 specialists, being 20·2 per cent. of the profession, of whom 4004—i.e., two-thirds—lived in towns having more than 100,000 inhabitants. The great majority of specialists were gynæcologists, after whom there followed in numerical order ophthalmologists, otologists, rhinologists, laryngologists, and then the surgeons. In 1907 the number of specialists practising in the great towns above indicated rose to 4160, being an increase of 156. In Dresden 44·6 per cent., and in Berlin 31·5 per cent., of the profession were specialists. Among the practioners in Vienna the specialists form only 14 per cent. of the whole, a proportion greatly below that of any large town in the German Empire. This comparison with the capital of Austria shows that in Germany something is obviously wrong in this development of specialism which has far exceeded the real wants of the population. Influential men who were associated with the compiler of the directory are of opinion that legislative measures are necessary for modifying the present condition of affairs.

Death of Professor von Mering.

The death is announced of Professor Josef von Mering of Halle, one of the most celebrated pathologists of Germany. He was born in 1849 at Cologne and after becoming qualified he was made an assistant to the celebrated Professor von Frerichs in Berlin. In 1878 he removed to Strasburg, where he was recognised as *privat-docent* and became extraordinary professor in 1886. In 1890 he was appointed chief of the medical polyclinic at Halle and in 1894 ordinary professor and chief of the medical clinic of the university in that city. The late Professor von Mering worked at physiological chemistry even while a student and afterwards made many important discoveries in that branch of medical science, especially in reference to diabetes. He discovered that diabetes might be produced in animals by phloridzin and by the removal of the pancreas. Other phenomena discovered by him related to the production of glycogen within the liver; and he introduced some new medicinal compounds, such as amylene hydrate and lipanin. He was the author of some text-books and wrote the chapter on diabetes in the great handbook of special therapy edited by Professor Penzold and Professor Stinzing.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The Health of the Pope.

DURING the last two decades of the life of the late Pope there scarcely passed a month without a sensational paragraph in the lay press announcing a *svenimento* (fainting fit) or a *deliquio* (swoon) as portending the speedy demise of the Holy Father. He lived to be 94, the only pontiff with the exception of his immediate predecessor Pius IX. who "saw the years of Peter"—that is, the quarter of a century during which the first of the Apostles is said to have filled the See of Rome. The reigning Pope is spared the experience (shall I say the amusement?) of inspiring so many paragraphs in non-medical journals as to his health—paragraphs which, in the case of Leo XIII., tempted an American monsignore to say: "Without the Holy Father's bodily condition to write about, what would the continental quidnuncs do for a livelihood?" Still, even Pius X. does not quite escape the solicitude of the lay journalist—the day now passing having witnessed a whole "flight" of announcements as to his having had a violent gouty seizure during the night which confined him to his apartment and caused the suspension of business, including the receptions already arranged. Inquiry, however, at the only trustworthy quarter—the consulting room of the Commendatore Petacci, His Holiness's body physician—reduced the report to its true dimensions, to wit, the and the necks more swollen than is usually seen after death. Bruising was general but not extensive in area, being more marked on the face and lower limbs, slight abrasions being seen in a few cases. There was a total absence of fractures and wounds as disclosed by external examination. In one case in which a post-mortem examination was made there was a trace of blood in the left ear but no fracture of the skull was found. In nine cases the tongue was not protruded, in six but slightly, and in one case well protruded. In 12 of the cases there was well-marked œdema over the front of the chest and in two of these it extended over the abdomen and thighs. The two post-mortem examinations presented practically the same features. Two of the more markedly congested cases were selected with a view to getting more definite results. The following are the brief particulars:—

---

[1] THE LANCET, Jan. 18th, 1908, p. 199.

Head.—Coverings, meninges, surface and substance of brain congested but healthy.

Chest.—No fractured ribs. Lungs congested and air passages clear. Heart, right side contained a small quantity of dark fluid blood.

Abdomen.—Liver and kidneys, slight congestion. Intestines, pale. Spleen, not congested but pale.

It is to be noted that there were no hæmorrhages in either case on the lungs or heart as is often found in cases of death by suffocation.—We are, Sir, yours faithfully,

J. HALL, M.D.,
Jan. 25th, 1908. H. F. HORNE, M.B., B.C.

THE NEED OF FEMALE MEDICAL MISSIONARIES.

To the Editor of THE LANCET.

SIR,—You have from time to time been good enough to make special missionary needs known through your columns. Will you now give publicity to the urgent need for more women doctors in the foreign field? Pioneer work waits to be begun in at least two districts of India; an overworked doctor in China needs a colleague; and now the grievous news of the death in January of Dr. Marie Hayes at Delhi makes the reinforcement of the staff of that mission a matter of urgent necessity. In a letter dated four weeks ago she said herself, "We desperately need another doctor." In two years from now there will, as we hope, be doctors qualified who are now going through the medical schools with this end in view. But these needs are immediate. We appeal earnestly for two medical women already qualified and able to undertake responsible work who would offer at once for this work, especially for Delhi. For particulars apply to the C.W.W. Candidates secretary, S.P.G. House, 19, Delahay-street, Westminster, S.W.

I am, Sir, yours faithfully,
Jan. 29th, 1908. H. H. MONTGOMERY (Bishop).

SUNSHINE IN 1907.

To the Editor of THE LANCET.

SIR,—May I be allowed to state that the records of the Meteorological Office for 1907 show that the island of Guernsey enjoyed the maximum of sunshine of any place in the British Isles—viz., 1859·7 hours. This, however, is considerably below its average for the last 14 years, which is 1916·2 hours.—I am, Sir, yours faithfully,

HY. DRAPER BISHOP,
Medical Officer of Health, States of Guernsey.
Health Office, Guernsey, Jan. 25th, 1908.

THE DESTINY OF CASE-BOOKS.

To the Editor of THE LANCET.

SIR,—Referring to your leader on the disposal of case-books I send you the following facts for which I can vouch. You are at liberty to make what use you like of them but please suppress names as one of the ladies is still living. A medical relative of mine died some 20 years ago, leaving as his nearest relatives a group of ladies and a nephew not a medical man. He had resided long in his house which was situated in a populous neighbourhood and was likely to be a good investment for a suitable successor. The ladies managed the transfer of the practice and of the lease of the house. Soon after a gentleman called on me and asked if I was the late physician's executor, and went on to state how annoyed he had been to see that gentleman's case-books giving full reports of cases, including those of the complainant's wife, for sale on a bookseller's counter. So strongly do I feel on the subject that I have destroyed all my case-books except the one I am using.

I am, Sir, yours faithfully,
Jan. 21st, 1908. M.R.C.S.

THE ORGANISATION OF THE PROFESSION.

(FROM OUR SPECIAL COMMISSIONER.)

ATTITUDE OF THE HONORARY STAFFS OF THE LIVERPOOL HOSPITALS IN REGARD TO PAYING AND INSURED PATIENTS.

Liverpool, Dec. 8th, 1907.

IN so far as the organisation of the medical profession is concerned Liverpool cannot in any way be considered a model town. Perhaps for want of proper leadership certain it is that there has been very little cohesion among the members of the profession. The fear also of doing anything that might in the remotest degree be likened to trade unionism greatly exercises the minds of some of the older and more prominent members of the profession. Nevertheless, there is to-day a very strong feeling of unrest and this has led at least to some attempts at organisation. Of late it is the honorary staffs of the hospitals who have been bestirring themselves and are actually seeking to form a union. It is not quite easy at first sight to determine whether this movement will make for the union or disunion of the profession at large. Some of the observations made in answer to my inquiries were not altogether encouraging. For instance, one of the most active leaders in this new movement argued that there were two classes of medical men, members of the hospital staffs and the general practitioners. Now each class accuses the other of being mainly responsible for the prevalence of hospital abuse. The general practitioner says that the competition of the hospitals robs him of his chance of earning a decent livelihood. On the other hand, I was assured that at the Liverpool Children's Hospital, when an inquiry was made into the matter, it was found that the general practitioner was the principal culprit. Then at the Southern Hospital a special superintendent had been appointed to investigate whether there was abuse. It was found that medical practitioners were themselves often responsible for abuse. When they were tired of a patient they would send him to the hospital. A case was described to me of a drunken and very dirty woman who was sent to the hospital with pneumonia and died in two days. She was fully able to pay. Then another case was that of a man who had nothing really the matter but was probably a club patient and generally a nuisance. Though there is undoubtedly something to be said on both sides there can be nevertheless no doubt that the general practitioner in Liverpool, as in most other towns, has suffered considerable loss through the facility with which patients who could pay fees have obtained gratuitous treatment at hospitals. Obviously the true remedy rests in uniting the members of the hospital staffs with the general practitioners in one single society where all would meet on equal terms and discuss their grievances in a friendly manner.

The nearest approach to such an organisation is the Liverpool division of the British Medical Association and the local secretary thinks that there is more cohesion among the members of the profession at Liverpool since the adoption of the association's new constitution. Nevertheless, it does not seem to me that the position is very promising because, if I am correctly informed, though the division has 67 members only about twelve or so attend the meetings. This is but a small number for so large a town as Liverpool. But what seems more significant is the fact that when a considerable number of the honorary staffs of the hospitals felt that they had grievances and it was necessary to take action, they formed a new society instead of bringing the matter before the local division of the British Medical Association. Then, again, the lay committees managing the principal hospitals have also joined together and are attempting to constitute themselves into a joint body so as to take common action. It is said that their principal purpose is to check abuse and to employ a uniform method to prevent persons who can pay fees obtaining medical relief. In this respect they are evidently greatly impressed by the Manchester example. When at Manchester inquiries

The Purification of Sewage.

For some time past the sanitary authorities of the large towns have been seeking for some simple and rapid method of sewage disposal and the ordinary sewage farms have been a great disappointment to their upholders. They have not been able to treat more than from 10 to 15 litres per square metre per diem. Coke filter beds, which are more active, can only deal with, and that very imperfectly, from 500 to 1000 litres. At a meeting of the Academy of Sciences held on Jan. 12th M. Muntz gave a very interesting account of some work which he had carried out in collaboration with M. Lainé in connexion with the method of purification by peat. A layer of peat, 1·6 metres thick, will deal with 4 cubic metres of sewage per square metre. The pathogenic bacteria are destroyed by nitrifying organisms and the number of organisms in a sample of sewage which before treatment was 3,000,000 is reduced after treatment to 300. Peat purification, besides being a valuable source of nitrogen, answers all the required provisions. There is reason to believe that it will very shortly be applied for the use of the large towns.

Absorption of the Upper Jaw in a Case of Syphilitic Tabes.

At a meeting of the Hospitals Medical Society held on Jan. 10th M. Danlos showed a long-standing case of syphilitic tabes complicated with perforating ulcer of the foot, in which some months ago all the teeth of the upper jaw had fallen out. Shortly afterwards the whole of the right side of the superior maxilla became absorbed and an ulceration appeared at the border of the gum; on the left side a spreading mass appeared which looked exactly like an epithelioma.

The Strike of Medical Men.

In a recent letter[1] I mentioned that the medical men of the department of the Somme had struck against some new regulations of the Assistance Publique. Under the auspices of the Syndicate of Medical Men of the department a meeting was held at the Hôtel de Ville of Amiens and it was decided to take no official part in the working of the Assistance in so far as regards medical practice after Jan. 1st, although it was agreed to attend the poor unofficially up to May 1st. The members of the committee of the Syndicate are now to be prosecuted for putting obstacles in the way of a department for public service.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Statistics of the Medical Profession in Germany.

ACCORDING to the Medical Directory of the German Empire (Reichsmedizinal-kalender), edited by Professor Julius Schwalbe and summarised in the *Deutsche Medizinische Wochenschrift* by Dr. Prinzing, the number of medical men in Germany at the end of the year 1907 was 31,416, showing an increase of 485 as compared with the previous year. This comparatively slight increase will apparently be soon converted into a large increase, because the number of medical students, which declined sharply some years ago, once more begins to rise. In the summer session of 1905 there were 6032 matriculated medical students, but the corresponding figures for the same period in 1907 were 7574, being an increase of 1500 within two years. It is obvious, therefore, that in four or five years, when these young men become qualified and engage in practice, the profession will again be overcrowded. Of the total number of medical men 18,985 resided in Prussia, 3459 in Bavaria, 2293 in Saxony, 1050 in Würtemberg, 1253 in Baden, 900 in Alsace-Lorraine, 692 in Hamburg, and the remainder in the smaller States of the Empire. It is interesting to learn from the statistical tables that in the great towns of more than 100,000 inhabitants there are 10 medical men per 10,000 inhabitants, 9·1 per 10,000 in towns having from 50,000 to 100,000 inhabitants, 7·0 per 10,000 in towns having from 10,000 to 50,000 inhabitants, and 2·9 per 10,000 in towns and villages having fewer than 10,000 inhabitants. The distribution of the profession throughout the Empire shows considerable inequalities and some curious instances of a deficiency of medical help are mentioned. For instance, the town of Bogetschütz in Upper Silesia, with a population of 19,942, has only one medical man, and this record number is nearly reached by Biskupitz in the same district with one medical man for 12,477 inhabitants. In Westphalia also there are two places of more than 12,000 inhabitants each with one medical man only. Other places with 14,000 and 13,000 inhabitants in Saxony have two medical men, and so on. All these places are situated in the mining districts where the population is comparatively poor. Most of the inhabitants belong to sick clubs and are at work away from home all day long, but nevertheless it is scarcely comprehensible how one medical man can suffice for nearly 20,000 people. On the other hand, Wiesbaden has 25·4 medical men per 10,000 inhabitants, Munich has 15·9, Strasburg has 14·2, Frankfort has 12·1, and Berlin has 11·4. It is noteworthy that specialists are assuming a position of growing importance within the profession as in 1906 there were in the whole Empire 6259 specialists, being 20·2 per cent. of the profession, of whom 4004—i.e., two-thirds—lived in towns having more than 100,000 inhabitants. The great majority of specialists were gynæcologists, after whom there followed in numerical order ophthalmologists, otologists, rhinologists, laryngologists, and then the surgeons. In 1907 the number of specialists practising in the great towns above indicated rose to 4160, being an increase of 156. In Dresden 44·6 per cent., and in Berlin 31·5 per cent., of the profession were specialists. Among the practioners in Vienna the specialists form only 14 per cent. of the whole, a proportion greatly below that of any large town in the German Empire. This comparison with the capital of Austria shows that in Germany something is obviously wrong in this development of specialism which has far exceeded the real wants of the population. Influential men who were associated with the compiler of the directory are of opinion that legislative measures are necessary for modifying the present condition of affairs.

Death of Professor von Mering.

The death is announced of Professor Josef von Mering of Halle, one of the most celebrated pathologists of Germany. He was born in 1849 at Cologne and after becoming qualified he was made an assistant to the celebrated Professor von Frerichs in Berlin. In 1878 he removed to Strasburg, where he was recognised as *privat-docent* and became extraordinary professor in 1886. In 1890 he was appointed chief of the medical polyclinic at Halle and in 1894 ordinary professor and chief of the medical clinic of the university in that city. The late Professor von Mering worked at physiological chemistry even while a student and afterwards made many important discoveries in that branch of medical science, especially in reference to diabetes. He discovered that diabetes might be produced in animals by phloridzin and by the removal of the pancreas. Other phenomena discovered by him related to the production of glycogen within the liver; and he introduced some new medicinal compounds, such as amylene hydrate and lipanin. He was the author of some text-books and wrote the chapter on diabetes in the great handbook of special therapy edited by Professor Penzold and Professor Stinzing.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The Health of the Pope.

DURING the last two decades of the life of the late Pope there scarcely passed a month without a sensational paragraph in the lay press announcing a *svenimento* (fainting fit) or a *deliquio* (swoon) as portending the speedy demise of the Holy Father. He lived to be 94, the only pontiff with the exception of his immediate predecessor Pius IX. who "saw the years of Peter"—that is, the quarter of a century during which the first of the Apostles is said to have filled the See of Rome. The reigning Pope is spared the experience (shall I say the amusement?) of inspiring so many paragraphs in non-medical journals as to his health—paragraphs which, in the case of Leo XIII., tempted an American monsignore to say: "Without the Holy Father's bodily condition to write about, what would the continental quidnuncs do for a livelihood?" Still, even Pius X. does not quite escape the solicitude of the lay journalist—the day now passing having witnessed a whole "flight" of announcements as to his having had a violent gouty seizure during the night which confined him to his apartment and caused the suspension of business, including the receptions already arranged. Inquiry, however, at the only trustworthy quarter—the consulting room of the Commendatore Petacci, His Holiness's body physician—reduced the report to its true dimensions, to wit, the of both taxation and insurance. Nevertheless, the actual facts do not as yet betoken any such revolution. The idea that compulsory compensation with the consequent general insurances taken out by employers for the employed would reduce the voluntary subscriptions paid to hospitals has not so far become manifest at Liverpool. Perhaps it is too soon for this recent legislation to take effect. In any case the subscriptions to the hospitals of Liverpool amounted in 1896 to £17,467 and in 1905 to £21,961, or an increase of 25 per cent. in ten years. The average legacies and donations for the last ten years were £30,585; the minimum sum being £21,714 in 1898, while in 1905 the average was greatly exceeded, the sum being £38,287. During the last eight years the average annual legacies amounted to £6860. The interest on invested funds has increased during the recent ten years from £12,882 to £16,434 in 1905. The payments made by patients and the fees paid by patients are put together under the head of earnings and these have increased in ten years from £18,353 to £22,800 in 1905. The total income from all sources of the 20 principal medical charities of Liverpool amounted in 1896 to £92,100 and in 1905 to £102,000. To this it may reasonably be objected that the income of the hospitals was bound to increase as the population had largely increased. Consequently I went to the Municipal Buildings and inquired what proportionate increase there had been in the ten years in question and was told that the borough of Liverpool had taken in two districts and the population had increased just a little over 11 per cent. In the districts outside the actual boundaries of the borough of Liverpool the proportionate increase of population would be still greater. It will be seen, therefore, that though the income of the hospitals has been well maintained it has only just kept on a level with the increase of population and that the figures are not sufficiently recent to show the effect which the new law on compensation to workmen, domestic servants, &c., may produce. It would appear that there is an economic change taking place in regard to the conditions of the hospitals generally and it is well that these new developments should be carefully studied by the members of the profession.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Presentation of Portrait and Complimentary Dinner to Dr. William Carter.

Dr. William Carter, late honorary physician to the Royal Southern Hospital, and professor of materia medica at the University of Liverpool, was on Jan. 18th entertained to dinner at the Adelphi Hotel as a token of esteem by his professional brethren and friends on the occasion of his retiring from practice and leaving Liverpool for Deganwy. The Lord Mayor (Dr. Richard Caton) presided. Highly eulogistic speeches were delivered by the Lord Mayor, Sir Alfred Jones, and his late colleagues, and Dr. Carter was presented with his portrait painted in oils.

Presentation of the Royal Humane Society Bronze Medal to Dr. B. A. Peters.

The Lord Mayor, on Jan. 21st, presented the bronze medal and certificate voted by the Royal Humane Society to Dr. Benjamin Alfred Peters, one of the house surgeons at the Royal Southern Hospital, for the gallant rescue of a young lady from drowning off the coast of Anglesey in August last. Dr. Peters recently graduated as M.B., B.Ch., at the University of Cambridge. The Lord Mayor complimented Dr. Peters on the gallantry which he displayed on the anxious occasion.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Death of Mr. William John Taggart, B.A., M.D. R.U.I., L.R.C.S. Edin.

ON Jan. 23rd Dr. W. J. Taggart, whose health for some time had been failing, died at his residence, Clonevein, Antrim, aged 74 years. Born at Thornhill, Randalstown, on Oct. 8th, 1833, he was educated at first for the ministry. He graduated B.A. of the old Queen's University of Ireland in 1855 and was ordained after completing his theological studies. He preached in Skipton and afterwards at Melbourne but resigned owing to ill-health, and returning to Ireland he studied medicine and graduated M.D. in 1863 and obtained the diploma of L.R.C.S. of Edinburgh in 1864. Settling down in Antrim, he began practice there and for many years was officer of health of the Antrim dispensary district and certifying factory and railway surgeon. Of a well-cultured mind and extensively read in general literature, Dr. Taggart kept up his medical studies. He had travelled a great deal and being a good observer and writer he could give a very clear account of what he saw and read. For many years he enjoyed a good practice. Dr. Taggart was buried in New Cemetery, Antrim, on Jan. 25th.

The Temperance Cause.

Under the auspices of the Belfast Women's Temperance Association Sir Victor Horsley spoke on Jan. 23rd at Belfast on "The Proper Use of Alcohol in Health and Disease," while in the evening he lectured in the Ulster Hall on "The Temperance Movement and its Bearings on the National Life." Dr. W. Calwell (president of the Belfast branch of the British Medical Temperance Association) and subsequently Professor T. Sinclair occupied the chair, and a vote of thanks was, at the conclusion of his address, passed to Sir Victor Horsley, on the motion of Dr. A. H. H. McMurtry, seconded by Sir John Byers.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Hebra's Prurigo by Fresh Liver Bouillon.

A NEW treatment for Hebra's prurigo has been introduced by M. Andrin who read a paper on the subject before the French Society of Dermatology and Syphilography on Jan. 9th. Every two days 100 grammes of fresh liver were taken and pulped; then a glass of boiling water was poured on to the pulp and the whole was allowed to digest for three hours. The bouillon after having been filtered through fine linen was divided into three or four doses and administered to the patient, a child. On the third day the itching had disappeared and the child slept quietly. After ten days' treatment the marks of scratching disappeared but the skin was still harsh. The quantity of bouillon was then reduced to one dose a day. Six weeks later no trace of the disease remained.

The Ophthalmic Reaction of Tuberculin.

At a meeting of the Academy of Medicine held on Jan. 14th M. Calmette read a paper upon the ophthalmic reaction of tuberculin, which he said gave a trustworthy diagnosis of tuberculosis. Its use was quite inoffensive and its value superior to the subcutaneous injection of tuberculin or to the cuti-reaction of von Pirquet. The reaction which it produces was purely local and it was of great value in the diagnosis of all forms of tuberculosis in their very early stages when the diagnosis of the condition is extremely difficult.

Anti-diphtheritic Serum in Affections of the Eye.

At the same meeting of the Academy of Medicine M. Darier read a paper in which he claimed that in infectious ulcers of the cornea, in infective penetrating wounds of the eye, in the complications which sometimes follow the operations for cataract, in certain forms of infective iritis, and in ophthalmic zona, he had obtained by means of two or three injections of Roux's serum a rapid arrest of the infection. The pain then ceased and a prompt recovery resulted, with a far more complete conservation of the vision than had been obtained hitherto by any other form of serum therapy. Simple serum acts ten times less powerfully than anti-diphtheritic serum. M. Darier, considering that anti-diphtheritic serum is useful not alone in ocular infection but in all forms of infection which have not at present a specific serum, recommends a more extended use of the remedy.

Nomination of a Professor.

The chair of experimental pathology, formerly held by Professor Charrin, which became vacant upon his death, has been transformed into a chair of general biology. By 25 votes out of 30 the professors of the College of France have recommended to the Minister as first choice for the new chair Dr. Gley, agrégé of the Paris Faculty of Medicine.

College, Chicago, and in 1891 professor of the practice of surgery and clinical surgery at the same institution. In addition to these posts he held the professorship of surgery in the Chicago Polyclinic and was professor of military surgery in the University of Chicago. From 1888 onwards he was the best known surgical lecturer in the United States and he used the enormous material made available to him by his numerous posts for the teaching of surgery to practitioners, the latter flocking to hear him from all directions.

As an operator he excelled, especially in abdominal surgery. He introduced decalcified bone plates for intestinal anastomosis, while his experiments on the pancreas showed the feasibility of operating in certain cases of well-defined lesions of that organ. As a military surgeon he took a prominent part in the Spanish-American war. He was commissioned lieutenant-colonel and chief surgeon U.S.A. army, and was commended by the Government for his surgical work during the Cuban campaign, as well as for making a valuable report upon the causes of typhoid fever among the troops. He was a sound writer, among the works from his pen which have been widely read on this side of the Atlantic being "Experimental Surgery," "Intestinal Surgery," "Principles of Surgery," and "Practical Surgery."

He was a member of many and various scientific societies and in 1897 was President of the American Medical Association, while in 1891 he founded the Association of Military Surgeons of the United States, of which he was president for two years. This brief record shows that Dr. Senn was not only an exceedingly able man but had an extraordinary capacity for work. He rose from an obscure position in a foreign land to become professor of surgery in Chicago, the second city of that land, with a world-wide reputation. And he was one of the distinguished men who deserve success on every ground, for he was universally and rightly esteemed for his rectitude and generosity. His public gifts were many. He endowed two rooms at St. Joseph's Hospital, Chicago, presented to Rush Medical College the Senn Clinical Building and to the medical department of the Crerar Library a valuable collection of medical books and monographs, including the entire library of the late Dr. William Baum, professor of surgery in the University of Göttingen, and that of Dubois-Reymond. We sympathise with our American colleagues in their loss of a real leader.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—T. Campbell (Section II.), *Liverpool*; A. R. Hardy, (Sections I. and II.), Manchester; and S. Speelman (Section I.), Amsterdam.

Medicine.—F. H. W. Brewer (Section II.), St. Bartholomew's Hospital; J. Brierley (Section II.), St. Thomas's Hospital; A. R. Hardy (Section II.), Manchester; W. P. Pinder (Sections I. and II.), Leeds; and N. C. Wallis (Section I.), London Hospital.

Forensic Medicine.—E. C. Banks, Manchester; H. A. Parker, St. Thomas's Hospital; W. P. Pinder, Leeds; and A. D. Rees, Charing Cross Hospital.

Midwifery.—M. Fisher, Royal Free Hospital; C. P. R. Harvey and G. F. C. Harvey, London Hospital; J. A. Laughton and A. D. Rees, Charing Cross Hospital; G. W. Simpson, London Hospital; and S. Speelman, Amsterdam.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and *midwifery*:—A. R. Hardy and W. P. Pinder.

FOREIGN UNIVERSITY INTELLIGENCE.—*Heidelberg:* Dr. Kümmel, Extraordinary Professor and Director of the Institute of Otology, has been promoted to the rank of Honorary Ordinary Professor.—*Lille:* Dr. Gaudier, *agrégé*, has been appointed to the chair of Clinical Surgery of Children and Orthopædics.—*Munich:* Dr. Ernst Weinland, *privat-docent* of Physiology, and Dr. Albert Jodlbauer, *privat docent* of Pharmacology, have been granted the title and rank of Extraordinary Professors.—*Tomsk:* Dr. Mysh, Extraordinary Professor of Theoretical Surgery, and Dr. Tikhoff, Extraordinary Professor of Clinical Surgery, have been promoted to Ordinary Professorships.—*Würzburg:* Dr. Jakob Riedinger, *privat docent* of Orthopædics, has been granted the title and rank of Extraordinary Professor.

AMONG the names of gentlemen called to the Bar at the Middle Temple last week is that of Mr. Edwin Smith, M.D. Lond., M.R.C.S. Eng., L.R.C.P. Lond.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE. —ALTERATION OF DATES OF PROFESSIONAL EXAMINATIONS. —The attention of candidates is directed to the fact that the examinations in medicine, surgery, and hygiene will in future be held in March and July, instead of April and September as hitherto. For particulars as to dates of forthcoming examinations our advertisement columns may be consulted.

THREE CASES OF CARBONIC OXIDE POISONING IN A WORKHOUSE.—On Thursday last week an inquest was held in the board-room of the Leighton Buzzard workhouse upon the bodies of two inmates who had been found dead on the morning of the previous Tuesday. A third occupant of the room who was found unconscious recovered under treatment. The jury found that the unfortunate women met their death from carbon monoxide poisoning which had been caused by structural defects in the ward.

THE RESPONSIBILITY OF PLUMBERS.—At the Technical College, West Hartlepool, on Jan. 17th, Dr. F. H. Morison, medical officer of health, gave a lecture to a large gathering of plumbers and representatives of health and water authorities. The Mayor of West Hartlepool took the chair. In the course of an interesting lecture he emphasised the great responsibility resting upon the plumber for the faithful execution of his work. He also referred in terms of eulogy to the work of the national registration of plumbers as helping to unite the craftsmen and citizens of large towns in enhancing the efficiency of the important industry on which all so largely relied for health and all dependent upon it. Alderman Macfarlane spoke of the interest shown by those in the trade in its general improvement. He referred to the desire of others also interested that legislation should be obtained as a protection against the unprincipled and incompetent. On the proposition of the Rev. Canon Cosgrave, seconded by Mr. R. D. Barker, a motion was unanimously carried declaring confidence in the existing organisation as offering the best means of securing registration on lines suited alike to the condition of the industry and the interest of the public and pledging the meeting to assist in promoting the object in view, particularly by appealing to the Government to initiate the necessary legislation.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BROSTER, A. E., L.R.C.P. Edin., M.R.C.S., has been re-appointed Medical Officer to the Brassington District of the Ashbourne Union, Derbyshire.

BURY, A., L.R.C.P. Edin., M.R.C.S., has been re-appointed Medical Officer to the Alstonefield District of the Ashbourne Union, Derbyshire.

COOPER, A. J. SISSON, L.R.C.P. & S. Irel., has been appointed Medical Officer and Public Vaccinator for the Fontmell District by the Shaftesbury Board of Guardians.

FRIEND, GERALD EDWARD, M.R.C.S., L.R.C.P. Lond., has been appointed Superintendent and Resident Medical Officer at St. George's Hospital.

GLENNY, EDWARD T., M.B., B.S. Lond., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Bristol Dispensary.

HALL, A., M.R.C.S., has been re-appointed Medical Officer to the Calton District of the Ashbourne Union, Derbyshire.

MCCANDLESS, R., M.B., B.Ch. R.U.I., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Rathfriland District of the county of Down.

MORRIS, LEONARD NEWSOM, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Bristol Dispensary.

MUDGE, Z. B., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Hayle District of the county of Cornwall.

PHILLIPS, HUGH R., M.D. Edin., has been appointed Physician to Margaret-street Hospital for Diseases of the Chest.

PINNIGER, WILFRID JAMES HUSSEY, M.B., B.S. Lond., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Bristol Dispensary.

TELLING, W. H. MAXWELL, M.D., B.S. Lond., M.R.C.P., has been appointed Honorary Physician to the Cookridge Convalescent Hospital, near Leeds.

YOUNG, EDWARD HERBERT, M.D. Durh., L.R.C.P., M.R.C.S., L.S.A., D.P.H. Lond., has been re-appointed Medical Officer of Health for Okehampton (Devon).

recurrence of a slight attack of the gout to which he is subject in midwinter, and this, by Dr. Petacci's orders, made him defer one or two minor "ricevimenti," while giving due attention to business of more immediate urgency. Later in the day I learn on the same authority that His Holiness is quite himself again.

Four Cases of Poisoning from Solution of Cod-liver Oil with Phosphorus.

Milan has just witnessed a deplorable incident, now under judicial investigation—the poisoning of four little children after the ingestion of solution of cod-liver oil with phosphorus. So far as the facts are already known, it would seem that the oil was not prescribed by a medical practitioner but that the father of the children, thinking that they required "something of the sort," procured it from a friend who, being a pharmacist, was able to get it in considerable quantity at a discount. So obtained, without the intervention (as stated) of a medical man, it was administered in a dose of one teaspoonful to each of the four children by their father, who did not know what the duly qualified physician would have told him, that the oil, thus procured from the manufacturing firm, had again to be diluted before administration—diluted in pure cod-liver oil in such quantity as to reduce the phosphorus to the proportion of 1 in 10,000. The unfortunate children, it would seem, were thus made to take a dose of the oil containing phosphorus 19 times in excess of the proportion required. The results were as immediate as disastrous. The little victims at once gave signs of violent internal disturbance—"nefrite fulminea," it was called by the physician who was summoned to treat them, or "explosive nephritis." Three died in a few hours in the hospital to which they had been removed, and the fourth is not likely to recover. As I have said, these are the facts now under judicial investigation; meanwhile they add another to the many "loud warnings" addressed to the Italian public against playing with such "edged tools," as medicines always are, unless professionally prescribed and exhibited. "Cross-counter therapeutics" has already numbered many victims in Italy—particularly in the southern provinces where the honourable traditions of the pharmaceutical calling are liable to be infringed by the setting up as "pharmacists" of adventurers who regard their business as little more than that of a retail dealer in groceries and who give "advice" and "prescribe" preparations in exchange for a fee to any customer who may enter their shop. The Government, I am glad to see, is being memorialised by the duly qualified pharmacists to put a stop to such invasion of their rightful province and it is to be hoped that legislation in the matter will take effect without the delays seemingly inseparable from Italian procedure.

A Hospital at Mogadiscio.

Italy has suffered in Somaliland a reverse almost identical with that which befell her arms 20 years ago at Dogali—a defeat which cost her the life of a gallant officer, the wounding of others, and the demoralisation of her native troops. Lack of equipment—that of field telegraphy in particular—is one cause of the disaster; in fact, but for the "compiacenza del filo inglese"—the courteous help of the English wire—she would not, any more than at Dogali, have known what had happened till many weeks afterwards. A movement to commemorate the fallen has been set on foot and will take the form of a hospital to be erected at Mogadiscio, the sea-port of Somalia Meridionale. This is a good beginning, to be followed, it is hoped, by other accessions to her resources in a colony lamentably deficient in the machinery required by such possessions.

Jan. 17th.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Uterine Gonorrhœa.

Dr. F. Paraldi of Kolozsvár states that the prospects of successful treatment of uterine gonorrhœa are not so unfavourable as has generally been believed. His conclusions are based on 244 cases treated in Kolozsvár. In the clinic of this city the chief object of treatment is the uterus itself and the cavity is treated actively from the commencement of the disease as long as gonococci are found in the cervix. The method adopted is to inject about two cubic centimetres of a medicated solution into the cavity of the uterus under strict antiseptic precautions, the cervix being dilated if thought necessary. For the past few years a 5 per cent. solution of sodium lygosinate, recommended by Dr. Fabinyi, professor of gynæcology, has been used and the injections have generally been given twice weekly. The preparation is a condensation product of salicylaldehyde and acetone and it possesses the advantage that, although strongly germicidal as regards the gonococcus, it has no irritating properties and does not in any way injure the tissues. Success or non-success was determined by bacteriological examination of the secretions. Of 128 cases treated with sodium lygosinate, 111 terminated in recovery, the usual number of applications being 10, and of the remaining 17, 10 were successfully treated by other means, so that only seven remained unrelieved.

The Treatment of Chancre.

Dr. Adolf Erdős of Naqyvárad advises the following treatment for syphilitic chancre. If the chancre is of recent date and situated on the free edge of the prepuce or of the labium as the case may be excision, followed by aseptic suture, is to be recommended. If the sore is ulcerated and of long duration, two months, for instance, and if excision is impossible, a few drops of a soluble salt of mercury, such as the benzoate, the biniodide, or the bichloride, may be injected around the chancre. Having washed the parts with a solution of sulphate of copper or nitrate of silver of strength 1 in 50 an ointment should be applied consisting of one gramme of white precipitate, half a gramme of resorcin, 30 grammes of simple ointment, and 10 grammes of lanoline. The same ointment can be used for the normal chancre. The internal treatment should consist as much as possible in mercurial injections. If these are not permitted the ordinary innunction treatment should be followed.

Wet Weather and Inflammation of the Tonsils.

The uncommonly wet weather which is prevailing during this winter in Hungary has caused an unusual number of cases of tonsillitis, most of which set in acutely and are well characterised. In several instances it was found that the inflammation extended to the nose and gave rise to suppuration of the accessory cavities. In disease of the middle ear the tonsils might require to be treated. Dr. Baumgarten has recently described his experiences regarding tonsillitis in a medical journal. He says that in cases of recurrent rheumatism when the palatal tonsils were not diseased he had repeatedly found inflammation of the pharyngeal tonsils and when these were removed the recurrence ceased. The pharyngeal tonsils seemed to be very important as regards the development of tuberculosis. From them the tubercle bacillus made its way into the lymph stream and was deposited in the glands, and when these became developed at the period of puberty the bacilli might set up tuberculosis. The treatment of acute inflammations of the pharyngeal tonsils consisted in insufflations, removal of the secretions, and gargling. Operation was only indicated when there were ear complications. For the prevention of recurrences extirpation must be performed and this ought to be radical.

Obituary.

NICHOLAS SENN, M.D. MUNICH.,

PROFESSOR OF SURGERY IN CHICAGO.

WE regret to announce the death of Dr. Nicholas Senn, the well-known surgeon, who died at his home in Chicago on Jan. 2nd from dilatation of the heart, aged 63 years. Dr. Senn was born in Switzerland on Oct. 31st, 1844, and went with his parents to the United States in 1852 and settled in Wisconsin. After a short experience as a school teacher he received some preliminary training in medicine from a medical practitioner in Wisconsin and in 1865 entered Chicago Medical College where he graduated with first-class honours in 1868. He began practice as a general practitioner in the state of his adoption but in a few years moved to Milwaukee where he became attached to the staff of the general hospital. In 1877 he returned to Europe and after studying at the University of Munich obtained the degree of medicine of that university. On his return to the United States he continued to practise in Milwaukee up to 1893, although he was from 1884 professor of the principles and practice of surgery in the College of Physicians and Surgeons, Chicago. In 1893 he took up his permanent residence in Chicago and from 1888 he was professor of the principles of surgery and surgical pathology in Rush Medical attendance upon the crew and other passengers and I was *not* allowed any extra pay. What I *really had was 10s.* per month *less* than the carpenter who also had extra pay for overtime.

I am, Sir, yours faithfully,

Jan. 25th, 1908. GAVIOTA.

BUDIN'S SYSTEM.

To the Editor of THE LANCET.

SIR,—I should be much obliged if any medical man who has tried the "Budin" system of the hand-feeding of infants—i.e., using undiluted sterilised cow's milk with a 4 per cent. standard of cream—would give me the benefit of his experience.—I am, Si , yours faithfully,

Jan. 25th, 1908. DUBIOUS.

SATURDAY (8th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

TUESDAY. - (*Pathological Section*). 8.30 P.M., Miss H. Chick: The Reaction Velocity of Disinfection. Dr. F. G. Bushnell: Cases of (1) So-called "*Leukæmia*"; (2) *Lymphocytic Leukæmia with* Malignant Lymphomata; (3) Sarcoma of Cervical Glands. Dr. J. H. Smith: The Absorption of Serum from the Tissues; Mr. F. A. Bainbridge: The Relation of Bacilli of the Para typhoid Group. Dr. J. A. Arkwright: On Non-virulent Diphtheria Bacilli. Dr. J. C. G. Ledingham: *Experiments in Phagocytosis.* Dr. J. B. Leathes: (1) Note on a Case of Chylous Ascites; (2) *Metabolism in Fever.* Mr. A. J. Young: The Action of Arsenates on the Fermentation of Glucose by Yeast-juice (with demonstration). *Dr. G. F. Petrie,* Mr. A. W. Robertson, Dr. R. D. Keith, Mr. E. A. Minchin, and Dr. A. C. Stevenson and Mr. J. D. Thompson: Demonstrations and Exhibitions of Specimens.

FRIDAY.—(*Laryngological Section*). 5 P.M., Dr. W. Williams, Sir *Felix Semon, Dr. J. Donelan,* Dr. StClair Thomson and Dr. J. Horne: Cases and Specimens.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—9 P.M., Mr. C. J. Symonds: Tuberculosis of the Kidney (illustrated by lantern slides, cases, and specimens). (First Lettsomian Lecture.)

WEST KENT MEDICO-CHIRURGICAL SOCIETY, Miller Hospital, Greenwich, S.E.

FRIDAY.—8.45 P.M., Dr. F. E. Taylor: Uterine Hæmorrhage.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, West London Hospital, Hammersmith-road, W.

FRIDAY.—8 P.M., *Pathological Meeting.* Specimens will be shown.

NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales's General Hospital, Tottenham, N.

THURSDAY.—4.15 p.m., Clinical Cases.

SOCIETY OF ANÆSTHETISTS, 20, Hanover-square, W.

FRIDAY.—8.30 P.M., Adjourned Discussion on Status Lymphaticus.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, 17, Bloomsbury-square, W.C.

TUESDAY.—8 P.M., Mr. E. M. Holmes: *The Adulteration of Drugs* and the Methods of Preventing it.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

FRIDAY.—8 P.M., Mr. W. Burton: The Hygiene of the Pottery Trade. (Shaw Lecture on Industrial Hygiene.)

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. S. E. Dore: *Clinique (Skin).* 5.15 P.M., Lecture:—Mr. J. W. T. Walker: The Diagnosis and Treatment of Malignant Disease of the Prostate.

TUESDAY.—4 P.M., Dr. B. Abrahams: Clinique (Medical). 5.15 P.M., Lecture:—Dr. G. H. Savage: Mental Disorders of Adolescence.

WEDNESDAY.—4 P.M., Mr. J. Berry: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. R. H. J. Swan: Malignant Cutaneous Tumours.

THURSDAY.—4 P.M., Mr. Hutchinson: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. R. Jones (Liverpool): The Present *Position* of Arthrodesis and Tendon Transplantation.

FRIDAY.—4 P.M., Dr. D. Grant: Clinique (Ear).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, road, W.

MONDAY.—12 noon: Lecture:—Dr. Low: Pathological. 2 P.M., Medical and Surgical *Clinics.* X *Rays. Mr. Dunn: Diseases* of the Eye. 2.30 P.M., Operations. 5 P.M., Lecture:—Mr. Dunn: Cases of Eye Diseases.

TUESDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 12 noon: Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Ball: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: *Diseases of the Skin.* 5 P.M., Lecture:—Mr. Bidwell: Clinical.

WEDNESDAY.—10 A.M., Dr. Ball: Diseases of the Throat, Nose, and Ear. Dr. Saunders: *Diseases of Children.* 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Scott: Diseases of the Eye. 2.30 P.M., Operations. 5 P.M., Lecture:—Dr. Beddard: Practical Medicine.

THURSDAY.—12 noon, Lecture:—Dr. Pritchard: Practical *Medicine.* 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M., Operations. 5 P.M., Lecture:—*Mr. Keetley: Clinical.*

FRIDAY.—10 A.M., Dr. M. Moullin: Gynæcological Operations. 2 P.M., *Medical and Surgical Clinics.* X *Rays.* Dr. Ball: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin. 5 P.M., *Lecture:—Dr.* Abraham: Cases of Skin Disease.

SATURDAY.—10 A.M., Dr. Ball: Diseases of the Throat, Nose, and Ear. Dr. Saunders: Diseases of Children. 2 P.M., Medical and Surgical Clinics X Rays. Dr. Scott: *Diseases of the Eye. 2.30 P.M., Operations.*

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—*Cliniques:*—10 A.M., Surgical Out-patient (Mr. H. Evans). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Throat, Nose, and Ear (Mr. *H. W. Carson*); *X Ray* (*Dr. A. H.* Pirie). 4.30 P.M., Medical In-patient (Dr. A. J. Whiting).

TUESDAY.—Clinique:—10.30 A.M., *Medical Out-patient (Dr. A. G.* Auld). 2.30 P.M., Surgical Operations (Mr. Carson). Cliniques:—Surgical Out-patient (Mr. Edmunds); *Gynæcological (Dr. A. E. Giles).* 4.30 P.M., Pathological *Demonstration:—Recent Cases* from the Post-mortem Department.

recurrence of a slight attack of the gout to which he is subject in midwinter, and this, by Dr. Petacci's orders, made him defer one or two minor "ceremonies," while giving his attention to business of more immediate urgency. Later in the day I learn on the same authority that His Holiness is quite himself again.

Four Cases of Poisoning from Solution of Cod-liver Oil with Phosphorus.

Milan has just witnessed a deplorable incident, now under judicial investigation—the poisoning of four little children after the ingestion of solution of cod-liver oil with phosphorus. So far as the facts are already known, it would seem that the oil was not prescribed by a medical practitioner but that the father of the children, thinking that they required "something of the sort," procured it from a friend who, being a pharmacist, was able to get it in considerable quantity at a discount. So obtained, without the intervention (as usual) of a medical man, it was administered in a dose of one teaspoonful to each of the four children by their father, who did not know what the duly qualified physician would have told him, that the oil thus procured from the manufacturing firm had again to be diluted before administration—diluted in pure cod-liver oil in such quantity as to reduce the phosphorus to the proportion of 1 in 10,000. The unfortunate children, it would seem, were thus made to take a dose of the oil containing phosphorus 10 times in excess of the proportion required. The results were as immediate as disastrous. The little victims at once gave signs of violent internal disturbance—"acute intoxication," it was called by the physician who was summoned to treat them, or "explosive nephritis." Three died in a few hours in the hospital to which they had been removed, and the fourth is not likely to recover. As I have said, these are the facts now under judicial investigation; meanwhile they add another to the many "final warnings" addressed to the Italian public against playing with such "edged tools" as medicines always are, unless professionally prescribed and exhibited. "Cross-counter therapeutics" has already numbered many victims in Italy—particularly in the southern provinces where the honourable traditions of the pharmaceutical calling are liable to be infringed by the setting up as "pharmacists" of adventurers who regard their business as little more than that of a retail dealer in groceries and who give "advice" and "prescribe" preparations in exchange for a fee to any customer who may enter their shop. The Government, I am glad to see, is being memorialised by the duly qualified pharmacists to put a stop to such invasion of their rightful province and it is to be hoped that legislation in the matter will take effect without the delays seemingly inseparable from Italian procedure.

A Hospital at Mogadiscio.

Italy has suffered in Somaliland a reverse almost identical with that which befel her arms 20 years ago at Dogali—a defeat which cost her the life of a gallant officer, the wounding of others, and the demoralisation of her native troops. Lack of equipment—that of field telegraphy in particular—is one cause of the disaster; in fact, but for the "compiacenza del'Inglese"—the courteous help of the English wire—she would not, any more than at Dogali, have known what had happened till many weeks afterwards. A movement to commemorate the fallen has been set on foot and will take the form of a hospital to be erected at Mogadiscio, the capital of Somalia Meridionale. This is a good beginning, to be followed, it is hoped, by other accessions to her resources in a colony lamentably deficient in the machinery required by such possessions.

Jan. 27th.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Uterine Gonorrhœa.

Dr. E. Fekete of Kolozsvár states that the prospects of successful treatment of uterine gonorrhœa are not so unfavourable as has generally been believed. His conclusions are based on 141 cases treated in Kolozsvár. In the clinic of this city the chief object of treatment is the uterus itself and the cavity is treated actively from the commencement of the disease as long as gonococci are found in the cervix. The method adopted is to inject about two cubic centimetres of a medicated solution into the cavity of the uterus under strict antiseptic precautions, the cervix being dilated if thought necessary. For the past few years a 5 per cent. solution of sodium hyposulphite, recommended by Dr. Fabinyi, professor of gynæcology, has been used and the injections have generally been given twice weekly. The preparation is a condensation product of sulphaldehyde and thymol and it possesses the advantage that, although strongly germicidal as regards the gonococcus, it has no irritating properties and does not in any way injure the tissues. Success or non-success was determined by bacteriological examination of the secretions. Of 135 cases treated with sodium hyposulphite, 111 terminated in recovery, the usual number of applications being 12, and of the remaining 24, 17 were successfully treated by other means, so that only seven remained uncured.

The Treatment of Chancre.

Dr. Adolf Havas of Nagyvárad advises the following treatment for syphilitic chancre. If the chancre is of recent date and situated on the free edge of the prepuce or of the labium as the case may be excision followed by aseptic suture is to be recommended. If the sore is ulcerated and of long duration, two months, for instance, and if excision is impossible, a few drops of a soluble salt of mercury, such as the benzoate, the biniodide, or the bichloride, may be injected around the chancre. Having washed the parts with a solution of sulphate of copper or nitrate of silver of strength 1 in 50 an ointment should be applied consisting of one gramme of white precipitate, half a gramme of resorcin, 20 grammes of simple ointment, and 10 grammes of lanoline. The same ointment can be used for the normal chancre. The internal treatment should consist as much as possible in mercurial injections. If these are not permitted the ordinary inunction treatment should be followed.

Wet Weather and Inflammation of the Tonsils.

The uncommonly wet weather which is prevailing during this winter in Hungary has caused an unusual number of cases of tonsillitis, most of which set in acutely and are well characterised. In several instances it was found that the inflammation extended to the nose and gave rise to suppuration of the accessory cavities. In disease of the middle ear the tonsils might require to be treated. Dr. Baumgarten has recently described his experiences regarding tonsillitis in a medical journal. He says that in cases of recurrent rheumatism when the palatal tonsils were not diseased he had repeatedly found inflammation of the pharyngeal tonsils and when these were removed the recurrence ceased. The pharyngeal tonsils seemed to be very important as regards the development of tuberculosis. From them the tubercle bacillus made its way into the lymph stream and was deposited in the glands, and when these became developed at the period of puberty the bacilli might set up tuberculosis. The treatment of acute inflammations of the pharyngeal tonsils consisted in insufflations, removal of the secretions, and gargling. Operation was only indicated when there were any complications. For the prevention of recurrences enucleation must be performed and this ought to be radical.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ABERTILLERY URBAN DISTRICT COUNCIL, EDUCATION COMMITTEE.—Doctor (female). Salary at rate of £150, rising to £200 per annum.

BANGOR, CARNARVONSHIRE AND ANGLESEY INFIRMARY.—House Surgeon. Salary £80 per annum, with board, lodging, and washing.

BIRKENHEAD BOROUGH HOSPITAL.—Senior Resident House Surgeon. Salary £100 and fees.

BLACKBURN COUNTY BOROUGH, EDUCATION COMMITTEE.—Assistant Medical Officer of Health. Salary £150 per annum.

BOLINGBROKE HOSPITAL, Wandsworth Common, S.W.—Surgeon.

BOOTLE, BOROUGH OF, HOSPITAL FOR INFECTIOUS DISEASES.—Resident Medical Officer, unmarried. Salary £100 per annum, with board, washing, and apartments.

BRIGHTON, COUNTY BOROUGH OF.—Medical Officer of Health.

BRIGHTON, SUSSEX COUNTY HOSPITAL.—House Physician, unmarried. Salary £70 per annum, with board, residence, and laundry.

BRIGHTON THROAT AND EAR HOSPITAL, Church-street, Queen's-road.—Non-resident House Surgeon for six months, renewable. Salary at rate of £75 per annum.

BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN.—House Surgeon. Salary £80 per annum, with board, rooms, and attendance.

BRISTOL ROYAL INFIRMARY.—Obstetric Officer. Salary £75 per annum. Also Junior House Surgeon for six months. Salary at rate of £80 per annum. Also Casualty Officer for six months. Salary at rate of £50 per annum. All with board, lodging, and washing.

BURY AND DISTRICT JOINT HOSPITAL BOARD.—Assistant Medical Officer for six months. Salary at rate of £50 per annum, with board, residence, &c.

CANCER HOSPITAL, Fulham-road, London, S.W.—House Surgeon for six months. Salary £70.

CITY OF LONDON LYING-IN HOSPITAL, City-road, E.C.—Two Physicians.

CROYDON, COUNTY BOROUGH OF.—Female Assistant to the Medical Officer of Health. Salary £250 per annum.

DEVONPORT, ROYAL ALBERT HOSPITAL.—Assistant Resident Medical Officer, unmarried, for six months. Salary at rate of £50 a year, with board, lodging, and laundry.

GREAT YARMOUTH COUNTY BOROUGH.—Assistant Medical Officer of Health. Salary £200 per annum.

GROCERS' COMPANY'S SCHOLARSHIPS.—Two Scholarships for original research in Sanitary Science, value £300 a year each, with allowance to meet the cost of apparatus and other expenses.

GROSVENOR HOSPITAL FOR WOMEN AND CHILDREN.—Honorary Registrar.

HUDDERSFIELD INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, residence, and washing.

IRELAND, LURGAN UNION WORKHOUSE AND FEVER HOSPITAL.—Resident Medical Officer (female). Salary £80 per annum, with apartments, laundry, and rations.

KING EDWARD VII. SANATORIUM, Midhurst, Sussex.—Junior Assistant Medical Officer, unmarried. Salary £100 per annum, with board, lodging, and attendance.

LAMBETH INFIRMARY, Brook-street, Kennington.—Third Resident Assistant Medical Officer. Salary £125 per annum, rising to £150, with residential allowances.

LONDON LOCK HOSPITAL.—House Surgeon in the Female Hospital. Salary £100 per annum, with board, lodging, and laundry.

OXFORD, RADCLIFFE INFIRMARY AND COUNTY HOSPITAL.—Junior House Surgeon for six months. Salary at rate of £80 per annum, with board, &c.

ROYAL DENTAL HOSPITAL AND LONDON SCHOOL OF DENTAL SURGERY, Leicester-square, W.C.—House Surgeon for six months. Salary at rate of £50 per annum.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, E.C.—Assistant Physician.

ROYAL NAVY, MEDICAL DEPARTMENT.—Examination for not less than 15 Commissions.

ST. PETER'S HOSPITAL FOR STONE, &c., Henrietta-street, Covent Garden, W.C.—Junior House Surgeon for six months. Salary at rate of £50 a year, with board, lodging, and washing.

SEAMEN'S HOSPITAL SOCIETY.—Surgeon at Branch Hospital.

STANNINGTON, NORTHUMBERLAND, CHILDREN'S SANATORIUM.—Resident Medical Officer (female). Salary £25, with board and residence.

STROUD GENERAL HOSPITAL.—House Surgeon. Salary £100 per annum, with board, lodging, and washing.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Rathmore, in the county of Kerry; and at North Leeds, in the county of York.

Births, Marriages, and Deaths.

BIRTHS.

HUNT.—On Jan 27th, at 3, Goldsmid-road, Brighton, the wife of Ernest Ewart Hunt, M.A., M.D. Cantab., of a daughter.

TELLING.—On Jan. 29th, at 29, Park-square, Leeds, the wife of W. H. Maxwell Telling, M.D., of a daughter.

DEATHS.

MARLEY.—On Jan 25th, at Mellinzay, St. Issey, Cornwall, Henry Frederick Marley, M.R.C.S., L.R.C.P., aged 75 years.

STEVENSON.—On Jan. 17th, at Sandhurst Lodge, Streatham, S.W., Lady Stevenson, wife of Sir Thomas Stevenson, M.D., aged 62.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE CERTIFICATES OF DEATH FOR ASSURANCE SOCIETIES.

A MEDICAL man writes:—

"Will you kindly express an opinion on the case stated below? A B, who is insured, dies. The nearest relative applies for a certificate of death and at the same time for a certificate of death for the assurance society. Should the relative be referred to the registrar for a copy of the original certificate or should another certificate (not on the forms supplied by the registrar) be given and a fee charged? I have been informed by a registrar that an assurance society is liable to a penalty for accepting as evidence of death any certificate other than the copy given by the registrar. If this is so, does it apply to both friendly societies and life assurance companies? I believe it is the custom of the medical profession to give such certificates, but it is pointed out that the certificates are invalid, though often accepted, and that the registrars are thereby deprived of fees which should come to them."

*** In answer to our correspondent we may point out that assurance societies stand on a different footing from friendly societies. The policies of the former bodies generally contain stipulations to the effect that proof of death of the insured must be "satisfactory" to the insurers. This means that the evidence of death must be sufficient, for be it remembered that the onus of proof is on the person claiming the policy money. We are of opinion that "a registrar" has misled our correspondent as to assurance societies being liable to a penalty if they should venture to dispense with the services of his brother officials. Most assurance societies are satisfied with the certificate of the practitioner who last attended the deceased, though sometimes circumstances require more corroborative proof. The stipulations (if any) in the policy must determine the method to be adopted by "A B's" relative, and probably our correspondent may justly earn a fee for giving a certificate—preferably not an ordinary official one—setting out fully the facts which the society is likely to require. As regards friendly societies it may be instructive to our correspondent and other readers to know that all the Acts relating to friendly societies previously in force were repealed in 1896 and a fresh code embodied in two new Acts which came into force on Jan. 1st, 1897, viz.: The Friendly Societies Act and the Collecting Societies and Industrial Assurance Companies Act. Section 61 of the former Act runs as follows: "(1) A registered society or branch shall not pay any sum of money upon the death of a member or other person whose death is, or ought to be, entered in any register of deaths except upon the production of a certificate of that death under the hand of the registrar of deaths or other person having care of the register of deaths in which that death is or ought to be entered. (2) This section shall not apply to deaths at sea nor to a death by colliery explosion or other accident where the body cannot be found nor to any death certified by a coroner or procurator fiscal to be subject of a pending inquest or inquiry." This section should adequately answer our correspondent's query as to the wisdom of giving death certificates to members of friendly societies.—ED. L.

A WARNING.

To the Editor of THE LANCET.

SIR,—I have just heard that "von Hohenfeldt," or as I believe he is now styling himself "Baron von Hohenfeldt," is again on the war-path, and within the last few weeks has victimised a number of members of the profession. His usual plan is to claim acquaintance, and indeed intimate friendship, with members of the profession who "just happen to be out of town when he most needs them." He also alleges that he is doing, or is just about to do, important work for some of the leading medical societies.

It is a wonder to me that medical men in such circumstances do not make use of their telephones; surely it would be easy to ring up the persons indicated and question them before falling a victim.

I am, Sir, yours faithfully,

Jan. 17th, 1908.

ONCE BITTEN.

SHIP SURGEONS AND VACCINATION FEES.

To the Editor of THE LANCET.

SIR,—Your correspondent "Bitten," whose letter appeared in THE LANCET of Jan. 25th, wants information as to the present rate of remuneration received by ship surgeons sailing to South America for vaccinating emigrants. I have just returned from a voyage to the River Plate. I had to vaccinate over 400 emigrants. I received nothing more than my ordinary monthly pay; not even thanks.

I am, Sir, yours faithfully,

Liverpool, Jan. 25th, 1908.

BIT.

To the Editor of THE LANCET.

SIR,—In reply to your correspondent "Bitten" I may say I completed a voyage in December to South America and I was made responsible for the vaccination of 53 Spanish emigrants besides medical although he ascribes it to variations in the splanchnic and somatic circulation.

What then is sleep? As night succeeds day and the parched and dusty earth is steeped in the cool and refreshing moisture of the sunless interval; as rest succeeds toil, and the strain of exertion stretches itself out in the grateful relaxation of mental and bodily effort; so sleep, in normal circumstances, wraps in the oblivion of unconsciousness the whole being exhausted by a term of conscious activity. The machinery of life cools down in sleep, the temperature falling slightly. The pulse on the whole becomes slower and it may be somewhat irregular. The depth of respiration is increased and its frequency diminished, as anyone may note who has the misfortune to hear another snoring. The eyes close and exclude all light. The pupils contract in proportion to the profoundness of sleep. The activity of all secretions is lessened. The work of life is carried on with a minimum of friction.

In this series of phenomena a difference is to be observed between the behaviour of the organs of voluntary motion and the involuntary organs. The voluntary muscular system is relaxed; its reflex irritability is lessened and its centres of motor activity are placed in abeyance. On the other hand, taking the pupil as a type of involuntary organic action, for we may leave out of consideration its accommodative faculty, we find that with the loss of sight and the closure of the eyelids the pupils contract as if still further to exclude any chance of sensory stimulation by light. During consciousness the exclusion of light, as we know, is associated with dilatation of the pupil. Now we also know that this contraction of the pupil, so characteristic of normally recurring unconsciousness, that is of sleep, is not necessarily associated with *abnormal* unconsciousness or the stupor attending certain diseased states. In many such conditions the pupil is widely dilated or varies in the degree of dilatation in one eye as compared with the other.

On the other hand, from lesions in certain parts of the brain and as the effect of certain drugs, unconsciousness is associated with an equal contraction of both the pupils, indistinguishable from that which attends normal sleep. The pupillary changes in sleep therefore are unlike the flaccidity of voluntary muscle in the same state, for the withdrawal of light from the reflex arc of optic nerve, pontic centre, and oculo-motor result, are not those one would expect as a result of such withdrawal of stimulus. Nor can the contraction of the pupil in sleep be attributed to a relaxation of the motor-sympathetic innervation of the radiating fibres of the iris, as there is evidence of the potential and actual activity of the sympathetic in the vaso-constriction of the cerebral vessels which has been noted by Durham, Donders, and others. There has been no adequate explanation of this marked difference in the behaviour of the pupil as compared with voluntary muscle, but the conclusion may legitimately be drawn that sleep is the *resting period* of consciousness and of all voluntary actions and only indirectly refreshes the ever-labouring heart and other organs whose perpetual activity is necessary to life. The unconsciousness of death and of apparent death, such as that associated with profound syncope, is coupled with a widely-dilated pupil and the complete loss of irritability of all organs, voluntary and involuntary.

The essential or primary element in the *mechanism* of consciousness is the brain cell—not its afferent channels of stimulation, not its blood-supply, but the cell itself. Not that the cell itself as apart from these could manifest consciousness, but it is evident that it is only in relation to the cell that the latter have importance. The condition of the peptic cell in the stomach during fasting and digestion, of the urinary cell in the kidney, of the essential cell of every other organ during activity and rest respectively, supports this argument. In sleep blood still irrigates the brain cell, and its processes are presumably still in connexion with it and with the rest of the body.

I have said that the primary element in the mechanism of consciousness is the brain cell, but behind all the factors named is the mystery of life. It might more truly perhaps be asserted, that consciousness is life manifest in certain brain cells, just as the exercised function of any other organ is life manifest in the cells proper to it; the brain or nerve cell, however, governs every other functionally active cell in the body in a way in which the latter do not govern it; nervous influence is as universally distributed as the blood. Since the discovery of the far-reaching processes of the nerve cell, as revealed by modern staining methods, it has been suggested that sleep may be due to the withdrawal cellwards or modification of these processes or of portions of them, and their loss of touch, in consequence, with afferent sources of stimulation. But of this there is no proof. Even assuming, however, such a hypothesis to be possibly correct, such a withdrawal would be a consequence, not a cause, of changes in the brain cell itself, and the fact that the sleeper may be wakened by sensory stimulation in greater or less degree proportionate to the profoundness of sleep rather argues that the afferent channels of sensibility still have touch of the external world, although *the centre, the cells on which they* converge, may not respond to stimuli falling upon them. It is also noteworthy that noises or stimuli which the mind has interpreted when awake frequently act rather as a lullaby than as a disturbance to sleep, while much lesser noises, not so interpreted and to which the individual has not become accustomed, serve frequently to rouse the sleeper to consciousness. The conclusion therefore seems to be warranted that a change in the cell itself is the primary cause of sleep, and that vascular and neural changes associated with sleep are effects, not causes, of the condition. What *the essential* cause of these intracellular changes is is unknown, but that they exist is indubitable. In the absence of more precise knowledge they can only be termed chemico-vital.

Normally a measure of exhaustion of the nerve cell from the exercise of function appears to be the essential cause of sleep. With this there may also be exhaustion of other organs, and more especially of the voluntary muscular system. But however the latter may participate in sleep-production the primary cause is the *need for rest* on the part of the brain cell itself, and its essential nature that chemico-vital change in it of which this need is the expression—a change of which we know no more at present than we do of the essential nature of life itself. Moreover, some interesting observations have been made on the appearance of nerve cells in conditions of functional activity and repose, and which can only, I think, be regarded as evidence that the cell creates as well as transmits energy. These visible changes in the bodies of cells respectively normally active and exhausted or at rest have been studied by many observers, and Ford Robertson thus summarises the general result of these investigations: "During normal activity the chromophile substance is utilised by the cell and slowly diminishes in quantity. At the same *time the* fuchsinophile granules of Levi increase considerably in numbers. The nucleus undergoes an increase in volume and the particles of chromatin adherent to it tend to become elongated. During rest the chromophile substance gradually accumulates again, the fuchsinophile granules diminish in numbers, and the nucleolus (nucleus ?) assumes a smaller volume. When the energy of the cell is exhausted by prolonged or excessive activity, the cell-body and the nucleus are distinctly diminished in volume; the chromophile substance of the cytoplasm is small in amount and appears diffusely granular instead of forming *local aggregations*."[3] These observations are surely sufficient to indicate that the organ of consciousness is the brain cell, or rather certain brain cells, in touch, on the one hand, with afferent influences by their receptive radicles and, on the other, putting forth the products of their activity by efferent channels, the whole being sustained in action by the blood, the nutrient fluid which bathes the organ of consciousness and source of mind.

But before passing from this subject we must remember that notable distinction between the results of mental cellular action and the action of unthinking cells, such as those of the stomach, liver, kidney, and spinal cord, or even of such cerebral cells as those the function of which is not emotional perception and ratiocination—namely, that the products of the organ of consciousness are more or less permanent, while those of unthinking cells are repeatedly produced, but each crop or series is itself transient and eliminated from the system. This permanent product of the organ of consciousness interests us on the present occasion because it may in its turn become a source of stimulation of the thinking cells. Itself an efferent product of their energy it may become in its turn an afferent source of stimulation. Memory, like thought, is cumulative. It has a *beginning*; much of it probably has an ending; some of it possibly is unending; but to inquire *as to this is* beyond our present purpose. These thoughts lead us to a short

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1907, which was completed with the issue of Dec. 28th, were given in THE LANCET of Jan. 4th, 1908.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1907 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

During the week marked copies of the following newspapers have been received:—*Manchester Chronicle, Daily News, Reading Mercury and Oxford Gazette, Nottingham Evening News, South Wales Daily News, Sanitary Record, Standard, Yorkshire Daily Post, Newcastle Chronicle, Dublin Evening Telegraph, Liverpool Courier, Hereford Times, Yorkshire Daily Observer, Nottingham Press, Wimbledon Gazette, Broad Arrow, &c.*

an appetite, the hunger of desire, may be an afferent cause of cerebro-cellular excitation as well as its over-gratification or improper indulgence. The infant at its mother's breast which obtains too little nourishment is frequently as sleepless as the child which is overfed or has improper food. In both cases there is a discomfort which is referred to the periphery, and in the case of indigestion certainly begins there. Moreover, what is true of the infant and its food is true also of the adult and of desires and appetites to which the infant is a stranger.

3. *Hæmic insomnia* is a term which, I think, may legitimately be applied to cases in which the exciting cause of sleeplessness is in the blood. As in the case of the cellular and neural group, the hæmic cannot perhaps be stated to act altogether independently of the other factors. There is reason, indeed, to think that the hæmic group is the smallest of those into which cases of insomnia fall, but our experience of anæmia, however originated and at whatever age, teaches us that defective nutrition and repair of the nervous system raise its sensibility and impair its stability. In the hæmic category we should also place cases in which the temperature is raised without the development of localised disease, as, for example, in the continued fevers and also various intoxications, whether with or without localised disease. The terrible insomnia, for example, of the delirious pneumonic, which in no small degree hastens the frequently fatal issue, belongs to this group. Drug and food agents also which disturb sleep may be regarded as acting through hæmic channels. Tobacco when smoked is possibly an exception to this rule, as it has a directly stimulating effect upon the sensory nerves of the oro-nasal cavities, but even in this case there is probably absorption in some measure into the circulation. The blood stream, moreover, may carry products of defective metabolism which act through the medium of the nervous system on the blood-vessels and induce a hypertonic state unfavourable to cerebro-cellular repose, for the most perfect unconsciousness is that which is associated with lowered activity and rest in every texture. Vascular hypertonus of a spastic and functional type has its organic expression in the arteriosclerotic rigidity of advancing life and old age, which is so often associated with defective sleep. Senile insomnia of this type is, indeed, exalted into a special variety by Sir James Sawyer in his interesting lecture on Sleeplessness.[4] Perfect normal sleep requires a normal minimum of physical and mental stimulation; unrest in one part of the body physical tends to rouse other parts which crave repose.

Prognosis.—The probability or otherwise of the subsidence of insomnia and the recurrence of normal rhythmical sleep depends naturally on the removeability or otherwise of the cause of disturbance. A good deal depends also upon the judiciousness with which protracted sleeplessness is handled by the physician and the strength of character of the patient whether the wakeful habit become fixed or subside. When insomnia is dependent upon physical lesion—ulcerative colitis, to choose a cause at random for the sake of illustration—it is self-evident that unless we can cure the condition, reducing thereby the discomfort and temperature often associated with it, the patient is not likely to drop into sound sleep without the aids of drugs. Similarly, when hæmic causes are at work the agents producing wakefulness must be eliminated or withheld before we can expect their effects to disappear. But in the large class of cellular insomniæ dependent upon abnormal excitation of the cells of consciousness, when we are face to face with a multitude of emotional and mental excitants, at times difficult even to discover, and when discovered frequently quite incapable of being removed, the obviation of effects as expressed in sleeplessness must depend largely upon the intelligence and strength of character of the patient. It is these cases which are so apt to acquire the drug habit, be it morphinism, chloralism, or any other "ism," which may in the first instance have been properly used to impose brain rest. A large proportion of these cases become chronic, less from the actual insomnability of the cells themselves than from their being kept active by the stimulus of apprehension on the part of patients lest they *may* not sleep and the baneful conclusion reached, usually erroneously, that they *can* not sleep without the aid of a hypnotic.

But, on the whole, the prognosis of functional as apart from organic insomnia is good. The normal rhythm tends to re-establish itself when the novelty of abnormal sleeplessness has passed off and sufferers begin to entertain the usual indifference towards what has become familiar. When, however, we are dealing with a patient whose reason is impaired and whose collective consciousness has lost the fixed points for rational arrangement, we can expect no normal rhythmical recurrence of sleep unless such disorder subside. Even in such cases, however, there is frequently a periodical recurrence of sleep alternating with equally rhythmical insomnia and excitement. Like the unconsciousness which follows an epileptic seizure, sleep follows recurrent psychical unrest as manifested by incoherent talkativeness with or without equally incoherent active violence.

Diagnosis.—Remembering what has already been remarked, that, whether we are dealing with the exercise of a normal function or with disorder of function, we cannot absolutely separate as independent factors the cell from its sources of neural stimulation or these from their indispensable blood-supply in the discrimination of one variety of insomnia from another, we have, nevertheless, to discover the preponderant rôle played in such cases by one or other member of this indissoluble functional tri-unity.

Infancy, at which period of life the storage of mental products is at a minimum, simplifies our task by leaving neural and hæmic sources of stimulation chiefly to be investigated. The organism is at this time chiefly concerned with the intake of nourishment, the elaboration of blood, the evacuation of waste products, and with growth. A comparison of the condition of these processes in a given case, with an accepted standard of health, will reveal whether they are normally exercised or defective, whether, that is, the child has too little or too much food or has improper nourishment, whether the evacuations are effectively carried out, whether the condition of the blood is normal for the age of the restless infant, whether the hard and soft textures of the body are of average form, size, consistency, and development, and whether the hygienic surroundings are such as are conducive to health. Defect in one or more of these particulars may reasonably be assumed to be causal of the restlessness which is manifested.

In the case of the adolescent and adult a similar physical examination will reveal facts equally capable of interpretation. But now we are dealing with a more developed mental organisation, with a stage of life which has other requirements, wants, desires, and attractions than the feeding-bottle, a warm cot, and a well-ventilated room. We have not even the comparatively simple task of dealing with the primitive savage adult but with a civilised being, girt round by necessity and laden with responsibility; with a creature, in short, which has ideas and ideals and is capable of being miserable if his ideals are not realised. At this stage, therefore, we may find a sound body yet a disturbed or unrestful mind, and by the exclusion of discoverable physical causes of unrest may correctly come to a conclusion as to the preponderant rôle played in the case by what I have termed cellular insomnia. This disturbance may be due to the over-reception of stimuli and consequent cogitation or to executive overwork either of head or hand or of both combined. In both instances the insomnia will probably be found to depend upon that exhaustion of cellular irritability which so frequently expresses itself in the more widespread functional disorders throughout the body which have been grouped under the term neurasthenia. The brain cells, like the plates of an electric battery, become exhausted by use and have to be raised out of the medium which generates their activity in order to revive. This period of recuperation is in normal circumstances sleep and its restitution when defective the task set the physician.

The treatment of sleeplessness.—There are some preliminary considerations which have a bearing upon the prevention and treatment of sleeplessness and which deserve mention. Except when insomnia is due to physical pain or discomfort, or to a state of the nervous system preceding serious cerebral disorder, or finally, in the case of tragic moral commotion, when the uneducated in self-control among the poor who cannot strictly be regarded as insane are perhaps more apt than the more reserved classes in the same circumstances to take refuge in suicide, sleeplessness is, in my experience, and I think I corroborate the general impression, more rare among the poor than among their wealthier neighbours. This conclusion on my part is based upon lengthened observation among hospital patients and the poor generally. It is remarkable how rarely in the mention of their diverse ailments sleeplessness is referred to by them. Serious nervous ailments such as epilepsy and various

A Lecture

ON

SLEEP AND SLEEPLESSNESS.

Delivered at the Great Northern Central Hospital on Dec. 18th, 1907,

By ALEXANDER MORISON, M.D. EDIN.,
F.R.C.P. LOND. AND EDIN.,
PHYSICIAN TO THE HOSPITAL.

GENTLEMEN,—A human being does not cease to be man when he becomes a patient. He remains such whether the host of a tapeworm or streptococcus or the subject of any other malady. This incontestable fact would not require mention were it not that it appears at times to be lost sight of when attention is directed too exclusively, as may happen, to the invading disease. Whether in health or in illness the mind plays an important part by the influence it exerts upon the body. This is more noteworthy in the case of the disorder of some organs than of others, and in none perhaps is it more so than in that of the cardio-vascular system which is not under the control of the will but is very sensitive to the influence of the emotions. It is obvious, therefore, that interference with the periodic repose of the organ of mind has a practical importance which justifies its particular study by the physician. A man may die exhausted "from the top" when other physical dangers threatening him have been successfully overcome.

While the hospital patient is often the victim of insomnia the satisfactory study of sleeplessness is best made in private practice, and I feel in addressing this audience on this subject that I am speaking to many who must have had a large experience of this condition. It is, moreover, one which requires a considerable experience both of disease and of life to discuss with advantage. It is probably because defective sleep is associated with so many states that text-books of medicine, notwithstanding its importance as a symptom of disturbance and cause of still further exhaustion, do not treat it fully under one heading. Like dropsy, it is referred to, if mentioned at all, in connexion with its causal conditions, and if this were done more systematically there would be no serious ground of complaint, but this is not the case. Comprehensive monographs and instructive papers have, however, been published from time to time on the subject and will repay perusal. Of these, it will suffice if I mention the monographs of Cappie and Macfarlane and the practical papers of Sir James Sawyer and Sir William Broadbent. In connexion with the purely scientific investigation of the subject the names of Durham and Donders deserve mention as early investigators, and since their time other physiologists and physicians have recurred to a subject which is always of interest.

In the present lecture I propose discussing so far as I can the factors which underlie sleep and wakefulness, the discrimination of one type of insomnia from another, the significance and prognosis of different varieties of sleeplessness, and the rational treatment of the condition. In short, I desire to discuss as briefly as possible, but with adequate fulness, the principles, so far as we can explain them, which underlie the etiology and treatment of insomnia.

Sleep and sleeplessness are synonymous with unconsciousness and consciousness. Intermediate degrees of these states are, in various proportion, conditions of partial unconsciousness or of partial consciousness—the dream state. Consciousness, whatever its psychological analysis or definition, is a property of the nervous system and of the highest plane of it—namely, of the grey matter of the cerebral cortex. Reflex actions we know may be provoked in decapitated animals and apparently even purposive movements manifested by them. The decapitated frog may raise its foot to all seeming in order to brush away a stimulation of the surface of the trunk, and the beheaded turtle may snap its jaws for a length of time after the severed head has lain far from its body. But the "spinal soul," if it exist at all, is peculiar to lower types of animal life, with which the physician has no immediate concern, and physiology teaches us that as the cortex is removed in layers unconsciousness deepens, although the functions of visceral life may continue little impaired. We may therefore conclude that, whatever the actual seat of consciousness, it stands in close relation to the cells of the cerebral cortex. Its manifestation among the higher animals is not possible without the agency of some cells in the brain any more than is the function of any other viscus without that of the cells proper to it.

Recent methods of investigating the anatomy of the cerebral cell have shown how far-reaching are its afferent sensory parts or receptive roots and their collateral tentacles or gemmules, and also how directly its efferent or executive processes transmit the nervous influence to the nerves or to the next in a series of cells conveying the motor impulse. In a sense the receptive radicles of a motor cell may be regarded as its sensory or afferent portion. This view of the relation of radicles or dendrites to cell-body and efferent fibres is regarded by those who accept this theory of the transmission of nervous influences as illustrative of what has been called the "law of dynamic polarisation"—that is, that nerve force entering at the receptive pole of a cell issues from the other, the axonic end, according to some by passing through the cell unaltered, and in the view of others modified by the action of the transmitting cell itself. Modern research has also shown the cell body to have a very complex organisation. Staining methods reveal constituents which hold and others which refuse the stain—the so-called chromatic and achromatic portions of the cell. Moreover, some of these constituents stain differently from others under the varying conditions of rest and activity. Thus some stain with certain reagents when the cell is exhausted and others with other stains when the cell is refreshed by functional repose. To these points I shall have occasion to refer again.

But consciousness, we also know, may be lost when animals are deprived of blood and restored with a renewal of the circulation. It follows, therefore, that the quantity of blood and character of the circulation have an influence upon the condition of the cells which manifest consciousness or unconsciousness as the case may be, and that whether unconsciousness be the result of a swoon or of sleep. We know further that substances introduced into the circulation may render an animal soporific or unconscious or, on the other hand, delirious and excited. The quality of the blood also has, therefore, an influence in the maintenance of consciousness or in the production of unconsciousness.

That the physical conditions obtaining within a closed chamber such as the skull, capable of resisting the atmospheric pressure in great measure, if not altogether, have an influence upon the character of the circulation within the skull may be granted. That the intracranial circulation, that is, differs in a measure from that in portions of the body not so protected, may be admitted. But the invariability of the intracranial blood content, which the doctrine of Monro assumed and on which some theories of sleep-production have been based, can no longer be regarded as a fact. That doctrine lived long and died hard, if, indeed, it be yet quite dead; so long indeed did it last that support for it was until recently sought in the assumed absence of innervation of the intracranial blood-vessels, because the innervation of these vessels had not been demonstrated. In a series of lectures which I delivered in Edinburgh ten years ago on the relation of the nervous system to visceral disease I was able, however, to show from specimens I stained in the laboratory of this hospital that the intracranial vessels were richly endowed with nerves, and, not only so, but that these nerves bore peripheral ganglionic cells. I afterwards learned that Obersteiner had previously stained these nerves and others also have done so since. My preparations were from vessels in the pia mater, but Ford Robertson figures an innervation of vessels in the cerebral cortex both of quadrupeds and men.[1] We therefore know now that intracranial vascular innervation is general and indubitable.

Some physiologists, notably Leonard Hill, have contended that, these facts notwithstanding, these nerves cannot be made experimentally to vary the calibre of the vessels they innervate, and for Hill the key to the intracranial lies in the splanchnic circulation.[2] It is manifest that this conclusion is difficult to accept, as nature is as averse to distributing functionless structures as she is to loving vacua. Observers have, moreover, shown that there is as direct a relation between cerebral activity and blood-supply as there is between the activity of any other group of functionally active cells and *their* blood-supply. This relation even Hill admits, reasons, and in quite a legitimate manner, they frequently continue to be used by the patient, openly or surreptitiously, after the need for their employment has gone. Their use, therefore, has to be constantly guarded from abuse. In the absence of physical pain and visceral commotion or discomfort the majority of reliable hypnotics in use belong to the methane series, of which alcohol, chloroform, paraldehyde, sulphonal, trianal, veronal, chloral, and chloralamide may be mentioned as examples. Why this group should have a special action in abolishing consciousness is not quite clear, notwithstanding some ingenious suggestions as to their *modus operandi*. Cushny[5] refers to the hypothesis of Meyer and Overton, according to whom their special solubility in lecithin and cholesterin, in which brain-cells abound, is a possible cause of this specific action. But, as Cushny points out, there are other substances resembling these in this particular of solubility which have no such narcotic effect. One would *a priori* expect that if this special solubility led to a more intimate incorporation of these substances with the brain cells their effect upon the latter would be more lasting than experience teaches to be the case. Thus the chloral habit, or even the habit acquired of taking that most disagreeable hypnotic paraldehyde, may exist for many years without apparently disabling the brain cells from doing much active mental work. But again, one meets with cases in which the drug habit appears to incapacitate its victims altogether for continuous mental application. These differences are not easy to explain merely as effects of the drug. There is evidently a personal factor involved, a personality which is a synonym for character, moral and probably also physical. The intelligent and industrious who dread the effects of insomnia may, like him who eats to work, take hypnotics to work. Others, like those who live to eat and who also live to sleep and to indulge in anything else that is pleasant, take hypnotics to squander in sleep the time they are too selfish or too inert or too ignorant to employ profitably when awake. But sleep is necessary for all; like rain it falls upon the just and upon the unjust, and, injurious as are the effects of the abuse of hypnotics in many cases, their actual destructive power is less than that of a continuous or persistent insomnia however caused. Regrettable as is the acquisition of the sleep-drug habit, there are cases, therefore, in which, as the lesser of two evils, the use of hypnotics for a considerable period seems unavoidable.

---

[1] Pathology of Mental Diseases, p. 163.

[2] Schäfer's Physiology, p. 142, Edinburgh and London, 1900.

With one or other member of the methane group bromides may be prescribed, alone, or with the addition of a derivative of hyoscyamus or cannabis indica. The well-known effect of the hyoscyamus group upon the peripheral motor nerve-endings tends to quiet muscular unrest and helps to induce that quietude of the extremities which favours the advent of sleep. Hyoscine itself is too powerful a drug for habitual use, but in the violent excitement of the insane may be invaluable as a muscular quietant. I have not infrequently found the use of the bromides during the day and a separate dose of one of the methane hypnotics at bedtime an effectual means of removing the consequences of insomnia.

The most difficult cases to treat among those possessed of reason are those in which artificially induced sleep only leads to an awaking in which the recognition of persistent causes of mental disturbance again present themselves. A certain proportion of such patients, usually with a congenital neuropathic strain, develop some form of maniacal aberration, temporary or persistent. Others without such strain may, after continued anguish, even die from that exhaustion which has in figurative language been termed a "broken heart," and which, if, like Balzac's callous husband who sent his wife's tears to a chemist for analysis, we try to define it more scientifically, we shall find it compounded of malnutrition, anæmia, loss of flesh, and the unresisted incidence of some intercurrent affection which proves fatal.

Those, however, are the cases in which the acme of distress is witnessed, in which physical pain is added to mental torture from other than physical causes. Even such cases one has at times known to reach a harbour of quietude and relief, but sometimes only for a brief period, before they again cross the bar on a voyage from which no ordinary mortal has ever returned. This last journey is, however, not infrequently taken on the initiative of the miserable patient himself, either by the self-administration of an overdose of hypnotic or by a despairing leap into space when death is welcomed as a friend. The suicide of the insomniac is not an uncommon event, even when the physical or mental suffering involved is not of such a degree as would tempt an unhinged mind to do the desperate deed. This only emphasises the importance of the subject we are discussing.

Yet another group of cases in this class find relief and recovery by learning to ignore the pressure of such persistent psychical excitants. These three kinds or degrees of disturbance belong, however, to an exceptional and aggravated group and tax the ingenuity of the physician not only as one prudently administering certain physical agents which act as narcotics but also as a philosopher with experience of life, whose undisturbed vision relatively to his patient's may enable the latter to walk through the fog of his circumstances into clearer day and with better hopes of overcoming his "strong enemy." The vast majority of cases of cellular insomnia, however, present no such difficulties and merely require judicious management upon the part of both physician and patient to be satisfactorily replaced by refreshing sleep. The prognosis, as I have said, in most cases of insomnia is good—a fact to be impressed upon the patient, for a succession of *nuits blanches* has a very depressing effect which naturally aggravates the condition and renders the task of the physician proportionately difficult. Sleep at night has frequently to be earned under these circumstances during the day. Robust and wholesome life, fully exercised during the day, throws itself more or less tired on to its couch at night to sleep soundly, in some cases the sleep of the just, and in others that of the unjust with a maximum of digestive power and a minimum of conscience. But, as a rule, when, from one cause or another, peripheral or central, or both combined, sleep has been disturbed, the return to refreshing slumber at night must be earned by a carefully regulated life during the day.

In extreme cases, both in men and women, there is no doubt a place for the "rest cure" and all its appurtenances. By this I mean the isolation of the individual in a nursing home, quietude, massage, careful feeding, and a curfew sounded comparatively early after sundown. But in most cases of insomnia, and especially among men, the nursing home should be avoided. It stands not far under these circumstances from the lunatic asylum and leaves a memory of nerve-wreck, or even of cowardice, which does not minister to self-respect. The steady performance of a compassable amount of work; the avoidance of excitement so far as possible; the cultivation of self-control; the production by circumspect and wholesome conduct, physiological and moral, of a centre of calm into which the individual may retire, *saevis tranquillus in undis*, when external sources of irritation bear upon him; the consciousness of a brave endeavour to perform duties which cannot be neglected without injury to himself or others; the well-spent day which leads to the cool and quiet pillow at night—this *day-sleep*, as such an attitude from its reduction of the friction of life may be termed, will gradually lead by recuperation of energy to sound *night-sleep*, often without the aid of drugs, though sometimes requiring their help for a time. The most annoying incidents which, suddenly thrust upon a man, induce cellular mental activity and the vaso-motor disquiet normally associated with that state spend themselves. Bravely looking the situation, whatever it be, in the face and translating thought into reasonable action will do more for the average and normally constituted man or woman who suffers from insomnia than more elaborate and invalid methods which enhance introspective activity, sap the self-reliance and self-respect of the individual, and perpetuate that subjective sense of dissatisfaction which turns the useless and mis-spent day into the restless and wakeful night. Indeed, Sir William Broadbent's words on the abuse of drugs in insomnia apply equally to the frequently unnecessary incarceration of such patients in nursing homes—"they diminish," he writes, "the resistance and impair the manhood of the individual."[6]

In the same category should be placed the practice of hypnotic suggestion as a therapeutic agent. There is a residuum of effete men and women in whom it is almost hopeless even to attempt to rouse that "heart for any fate" which brings its own reward in steady effort and in calm repose, who drift at times into the hands of the practitioner of hypnotism to be coaxed into an oblivion not otherwise attainable except by drugs. But the type suitable for his consideration of some psychological points bearing upon our present theme.

---

[5] Text-book of Pharmacology, p. 126.

[6] THE LANCET, Jan. 27th, 1900, p. 215.

Perhaps no subject has exercised more the ingenuity of the thoughtful than the nature and actions of mind, and classifications of the different manifestations of human consciousness have been very numerous. The phenomena of consciousness appear to be subjective and objective, involuntary and voluntary; I had almost said passive and active, but passivity is properly applicable only to the reception of a stimulus by the organ of mind. The "Senses and the Intellect," to use the title of Bain's well-known treatise, perhaps expresses this division sufficiently. *Feeling* and *expression*, in thought, word, and deed, embrace all phases of mind, for all these may be phases of an internal process of which there is no overt manifestation. Feeling in the first instance can of necessity only be appreciated by the individual. It is purely subjective. A thought need not be apparent to others, a word need not be uttered, and an act need not be manifested. A thought is an act, a word is an act, and a resolve is an act. They are all within the sphere of will, to be liberated or repressed, as the individual desires.

To enter at length upon the field of fine distinctions in moral philosophical terminology is, however, scarcely germane to our present purpose. It will suffice if I explain with greater detail what I mean by subjective and objective, involuntary and voluntary phases of the operations of mind. The subjective operations of mind deal with the *feelings*—with love, self-esteem, hate, joy, grief, hope, fear, certainty, uncertainty, satisfaction and dissatisfaction, however they may be provoked, and however they may be further divisible in relation to the desires and appetites of our nature. Primarily they appear to spring from our possession of life and the impulse to preserve and perpetuate it. When we cease subjectively to feel, our mental operations become objective; our feelings shape themselves towards intellectual effort and transpire in thought, word, and deed. Such action completed, we may again lapse into satisfied or dissatisfied subjectivity. We may feel satisfied or dissatisfied. Satisfaction is rest; dissatisfaction is unrest or continued stimulation. This may appear to some but prolix verbiage, but I hope to show that it has a bearing upon our theme in my endeavour to explain the phases of cellular action which underlie consciousness and which tend, according to their nature, to encourage or to thwart the normal advent of rhythmical sleep.

Another point of importance in relation to sleep and sleeplessness is temperament. While man may be regarded as essentially one in his nature—scratch anyone and he will bleed much like his neighbour—it is nevertheless a truism that no two men are precisely alike. In no respect is this more so than in his mental nature, in the sphere, that is, of his consciousness. These differences of temperament may be assumed to be based on physical differences which may escape detection by the test-tube or microscope, but which are unmistakeably written in the objective manifestations of mind, in the conduct and bearing of the individual. A man, the intellectual side of whose nature is well developed, may exercise a control which imposes outward calm on a naturally perfervid disposition, and may give a surface impression of quietude which is foreign to his nature. This is not likely to mislead those who have any faculty for distinguishing the quick, energetic type usually associated with the possession of powers of rapid perception, rumination, and expression, from the slower, more deliberate, and less impulsive type. The majority of men of the former type are easily recognised by rapidity of speech when discussing matters which interest them, frequently emphasised by gesture and decorated with metaphor or imagery which may easily degenerate into extravagance of language or oratory. Their emotions are easily roused and they sometimes advocate with enthusiasm causes not necessarily sound in themselves. What is true of the neurotic man is true also of the neurotic woman, "only more so," to use a conventional phrase. The intelligent man of a naturally imperturbable disposition, on the other hand, is not as a rule the stuff of which poets, orators, and artists are made. His ratiocination is often slower, but often also more accurate than the neurotic's and the results of his cogitation frequently more reliable, while his actions and expression are less explosive but often more sustained and effective. Dogged sometimes does it, after the rocket has flared into the heavens and returned as the unpicturesque stick. There is, of course, the contingent possibility of tardy worth arriving on the scene too late to be of much use to himself or anyone else. But that is a detail which probably would not disturb him to the same extent as it would his more impetuous fellow. Both types when not dullards may no doubt be raised to white heat on sufficient occasion, the one quickly and the other slowly, but the brain-cell rest of the quick is more easily disturbed than that of the slow. Both, however, in virtue of their intelligence tend to return to the normal, for each creates for himself a centre of calm by clear insight into circumstances and possibilities. Neither of them, that is, desires long a slice of the moon if that luminary cannot reasonably be reached with a knife.

When we come to a lower plane and the subjective differences remain while intelligence is less marked, the phlegmatic have the advantage still more. They have a bovine imperturbability which is conducive to good digestion and to doing nothing, which is sometimes safe. The stupid neurote, on the other hand, is apt to be hurried into precipitate and often unfortunate action, not calculated to hasten his return to normal quietude and rhythmical sleep. Alcoholism, morphinism, and other bad habits are more easily acquired by the stupid neurotic than by the stupid phlegmatic person, although, unfortunately, many a brilliant and lovable nature has also succumbed to the same fatal influences to escape the torture of insomnia.

These temperamental differences which influence cellular excitation, influence also disturbances of sleep due to afferent neural and to hæmic causes. Sleeplessness may therefore be placed in three groups—cellular, neural, and hæmic. Not that these can be altogether detached the one from the other any more than these factors can be separated in the production of normal consciousness, but inquiry will usually elicit in cases of insomnia which of them plays the predominant rôle in a particular case. But whatever the immediate cause of sleeplessness the effects of it, though varying in degree, are the same in kind and the opposite of those observed in sleep. Thus, the temperature of the body is slightly raised, visceral actions are quickened, and secretion, especially the urinary secretion, is increased, not diminished. The latter phenomenon is, like all the phenomena of sleeplessness, most evident in the neurotic insomniac and is due to the higher vascular tension involved which causes a larger excretion of urine by the kidneys, for the increased output is usually of a limpid character.

Let us now consider these varieties of sleeplessness seriatim.

1. *Cellular insomnia.*—The majority of cases of disturbed sleep are referable to this class, as might *a priori* be expected; indeed, most papers on insomnia deal solely with this class. We need not attach too much importance to statistics which are rarely based upon a sufficient number of cases to carry conviction to the mind of the lesson they seem to point. Such as they are, however, they indicate the preponderance of the cases I have termed cellular. Thus, the late Dr. Macfarlane in his thoughtful work found that neurasthenia and worry were responsible for 26 per cent. of cases of insomnia calculated from a total of 273 cases. Although gout, overwork, the menopause, dyspepsia, alcoholism, and senility are among the other causes which he mentions it is probable that the cellular factor played a not insignificant part in many of these also. We must distinguish, moreover, between the subjective and objective causes of cerebro-cellular disturbance. Of these the former, dealing with sensibility and emotion, are more likely to preponderate than those dealing with executive overwork. Worry kills and keeps awake more frequently than work. There is relief and attainment in action which does not appertain to the unutilised energy of subjective or unexpressed feeling. Action takes a man out of himself and thus favours repose.

2. *Neural insomnia*, in the sense in which I have used the term, includes all those cases in which sleep is disturbed by afferent impulses of a more strictly physical kind. Pain and bodily discomfort in various degree and originating in whatever system, be it cutaneous or pulmonary, renal or hepatic, gastric or intestinal, may rouse conscious activity and prevent its dropping into the rhythmical repose natural to it. Thus such efferent impulses may effect directly, as is the case in pain and local discomfort from any cause, when it is sufficiently pronounced to be perceived by the mind as such; or indirectly when the combined influence of afferent stimulation and cerebral excitation raises the blood pressure. We must remember also that the absence of satisfaction of

process of saturation of the human skin was an essential one in its disinfection and in making it antiseptic. And by antiseptic I mean that bacteria would refuse to live in it. So we have been trying of late to saturate our skin with biniodide of mercury. The way in which we proceed is this: we take the ordinary solution of spirit of biniodide of mercury, which is made of 75 per cent. of ordinary rectified spirit, and a solution of mercuric iodide in iodide of potassium to make it of a strength of 1 in 500. The water amounts to 25 per cent., and the reason for this addition is well known—and I need hardly dwell upon it—that when disinfectants or antiseptics are mixed with alcohol; or with glycerine, or with fat they become inert. A solution of disinfectant with spirit becomes potent again after the addition of water, and for practical purposes we find that a dilution of 25 per cent. suffices. Now as to the way in which we try to get the antiseptic into our skin. Biniodide suits my skin and it is a good antiseptic, and we have tested its effects on the tissues. With tissues which were washed with biniodide of mercury of a strength of 1 in 4000 I am unable to see the slightest change. Mr. A. J. Kendrew, to whom I am much obliged, showed me first sections of ordinary muscle and of ordinary fat and then afterwards some which had been washed with 1 in 4000 biniodide of mercury, and I was unable to tell which was which. So I think we may guess that many of the statements which are made about the harmful effects of chemicals upon the tissues will not apply to biniodide of mercury. I think that on looking through the literature you will find that the statements which are made apply to very strong solutions of sublimate and to strong solutions of carbolic acid, which you know combine with albumin very freely.

Now, how do we get biniodide of mercury into the skin of our hands? After the hands have been washed they are put in spirit and biniodide 1 in 500, and afterwards put into a watery solution of 1 in 500. That is repeated four times at least, until we get 1 in 500 watery solution absorbed into the depths of the skin. Dr. Hurtley has ascertained that skin treated in that way contains an appreciable amount of antiseptic. Also, I believe that it will bear tests which skin treated in other ways will not bear. Haegler tested the asepticity of skin by dragging across it pieces of silk which were afterwards dropped into broth or put on to the surface of a culture. And we have found that after these more rigorous efforts we have been able to drag pieces of silk through the fingers without infection. But this is not the most stringent test because the fingers are easy to disinfect. Therefore it has been dragged many times through the palms of the hands, which you know have numerous sweat glands upon them, and a large proportion of that silk was not infected. We have not been practising this stringent test for very long, but I am quite within the bounds of veracity in saying that 40 per cent. of our tests were aseptic. As a matter of fact, I believe the proportion is higher. Further, if some gentleman will apply his mind to this subject he will discover a better method than any of these for the disinfection of the human skin.

You might say this to me: "Why, if the skin of the hands is so difficult to disinfect, do you not wear gloves?" I have already partly answered that question. The assistants at operations should certainly wear gloves. I am not saying anything that is not quite kind or polite when I say that the assistants at operations cannot have had a very large experience in the methods of disinfecting their hands, and have already said that in disinfection of the hands experience counts for a very great deal. Why should not an operator wear gloves? Many operators do. I have been wearing gloves for a great many years. When I was surgical registrar I used rubber gloves in all the post-mortem examinations and was conscious that I could not feel properly in them. And with gloves on I could not during an operation put my fingers down into the depths of the pelvis and extract an adherent vermiform appendix or an adherent and suppurating Fallopian tube with any degree of confidence. But, for a great many operations, such as rectal examinations, operations for hæmorrhoids, for fistula, and for operations on septic sinuses and so forth, surgeons ought to wear gloves. Surely it must be easier to disinfect hands which have not been contaminated than to disinfect hands which have.

We come next to another matter and that is the testing of the skin of the patient. You probably know that the difficulty in disinfecting the skin of the patient depends to a very great extent upon the region from which it comes and you may say offhand that regions which have upon them hair and consequently deep sebaceous glands and which have long sweat glands are additionally difficult to disinfect. This is true with regard to the scalp; the skin of the back is also very difficult to disinfect, so is the skin of the groin and the skin of the armpits. The easy skin to disinfect is in front of the limbs, of the abdomen, and of the chest. The bearing of this is obvious and you will take additional pains in endeavouring to saturate the more difficult regions with disinfectants. The difficulty which you will meet with is the presence of fat in the sebaceous glands of the skin. And you will observe that I have almost put the difficulty in the order of the abundance of the sebaceous glands. I wonder if anybody has ever succeeded in disinfecting the scalp. If you are aware of the difficulty your minds will suggest to you methods of overcoming it. And you may have observed that we use all sorts of materials for extracting sebaceous matter from the human skin. Ether is good but it speedily evaporates. Turpentine is good and has some disinfecting properties. We have tried benzol and I do not see why we should not try others of the petroleum series. We also use alcohol as part of the process of disinfection. It is not only a disinfectant in itself but it is useful in the removal of grease. Again I say about disinfection of a piece of skin what I have already said to you about disinfection of the hands. As our realisation of the extreme difficulty of the process has grown, so we have become more successful. I regret not to have had time to abstract all the returns which the house surgeons and pathological clerks have with such great kindness sent me. But I believe it to be correct to say that we succeeded, taking every region of the body into consideration, in at least 75 per cent. of our attempts. I believe that is well within the truth. And it is comforting to think that in some of the regions where the effects of skin infection would be most disastrous it is least likely to occur. So that one feels very few qualms when called upon to open a knee-joint for the removal of a loose cartilage, as one had to do yesterday.

With regard to the disinfection of the human skin there are certain further tests which can be applied. One of the tests which we are endeavouring to apply on every occasion is the removal of a stitch from the wound when it is dressed and placing that stitch into broth. And here, again, with increasing experience and increasing trouble we are getting a very much higher proportion of asepsis. I ought to say that we are not contented with our methods of closing wounds. The stitch-hole often has a small red point around it which is objectionable. We have tried celluloid thread, which is better, but that often has a red point round it. I am not by any means certain that we may not try other means and shall suggest to the house surgeon that some of our wounds be closed with metal clips. The meaning of all this is—and I do not know what the house surgeon will think of it—that I shall not be content until we get perfection.

I now come to another point in regard to the source of wound infection, those which are due to the environment of operations. And I had this point brought home to me in a very painful manner when the temporary theatres were opened. This hospital is ultimately to be equipped with proper theatres and I cannot tell you what a very difficult problem the arrangement of proper theatres will be. I have learnt a very great deal from having to operate in different kinds of theatres in this hospital and hope that either I or somebody else will ultimately evolve the plan of a suitable operating theatre. But to come back to my painful experience. I had to perform a gastro-enterostomy and also a complete removal of the breast and also the removal of a myxo-sarcoma from the brachial plexus on one day. In those times the theatre had no bay in it for the audience. And that day, for some reason or other, there was a large audience, so that the floor of the theatre was full of people. The atmosphere was dreadful and the end was that the unfortunate patient who had gastro-enterostomy performed died from a slow form of septic peritonitis, although there was no leak nor any reasonable probability of some fault on the part of the operator. Next, the case of complete amputation of the breast suppurated freely but the patient fortunately survived. Lastly, the myxo-sarcoma of the brachial plexus healed by first intention, but by the time that operation was done most of the audience had departed, and the operation was a speedy one and did not involve exposure to a polluted atmosphere for over an hour. That was a sad experience.

And now I want to discuss with you for a few minutes the psychoses are apparently, though perhaps not actually, as common among the poor as the rich. I say apparently, because the poor as a body so greatly outnumber the rich. This fact, if such it be, that insomnia is rarer among the poor has a certain significance. The poor are neither overfed, overclothed, nor idle as a rule, except when unavoidably unemployed. I do not speak now of the submerged "unemployable" but of the labouring poor as a body, the peasantry, urban and rural, who are the source and foundation of a nation. No one will assert that these are free from anxiety or that they have not as tender a regard for their offspring and relations as their wealthier neighbours. It must therefore be that such sleeplessness as they suffer from must either be regarded by them as a minor evil or that their conditions of life are less favourable to its occurrence. I think the latter conclusion may be accepted as correct, for no human being can work hard unless he sleeps well, and as the poor must work hard they probably also sleep well. The workman's energies are largely peripheral, so to speak, or executive. He is hands as a rule, not head. His food is moderate in quantity and plain. He is not superfluously clothed day or night. He is inured to hardship. He is little concerned in laying up for himself "treasure upon earth" possibly from lack of opportunity, and is inclined to believe that the evil of each day suffices for it.

All these conditions of hardihood and hard work lessen as we pass into the so-called higher strata of society. Man then becomes more subjective in his mood, more fastidious in his appetite, "softer" generally, and demands more as his right, being proportionately discontented when his expectations are not realised. What he terms refinement takes the place of more natural and simpler conditions. Whether as a consequence of these altered circumstances or not, minor nervous disturbances bulk large in his imagination, and it is, I think, a fact admitted by most observers that insomnia not dependent upon physical pain or great moral distress is more common among the upper classes than among the lower orders.

Now we cannot expect the nervous system, modified by education, easy circumstances, and hereditary influences, suddenly to divest itself of all these properties as a man takes off an overcoat. It takes time to make the modification; time is also necessary to unmake it. But it is possible for the wealthy and cultured classes to lead the simple and strenuous life and not hopelessly to degenerate in the lap of luxury. To cultivate, that is, the sound body which holds the sound mind. To keep themselves fit—*toujours en vedette*, and to avoid becoming *blasé* in a life which may be made solidly interesting and beneficial from the dawn of intelligence to its close.

When, however, we have the particular instance of a given insomniac in more or less easy circumstances to deal with we cannot expect him suddenly to assume a Spartan mode of life and regard his state philosophically. We have to take him as he is, and endeavour by degrees to make him, if possible, what he ought to be. The young and potentially vigorous must be fed plainly, advised to take regular exercise, increasing with their improvement of tone, and placed under circumstances in which, day and night, they have an abundance of fresh air, a cool head, and comfortable surface warmth. The older, and especially those with a measure of persistently raised blood pressure, require to be particularly careful as to surface warmth in bed, and especially warmth of the feet, which helps to reduce vascular tension. To secure a cool head in bed the ordinary feather pillow is not a good contrivance. It may certainly be so arranged as not to heat the head for a time but a head-rest may be constructed which is much cooler. Inflated pillows are usually more or less hard and uncomfortable. A "pillow" has, however, been made under my directions by Messrs. Krohne and Sesemann of Duke-street, London, W., which, in my opinion, fulfils the indications better. It is a lightly padded iron frame covered by a case of smooth webbing and open at both ends on which the head and neck rest comfortably, surrounded by air of the same temperature as that of the bedroom. This pillow, which has been called the "open air-pillow," may be used under all circumstances in which such coolness is desirable (see Figs. 1 and 2). Indeed, the so-called hop pillow, consisting of a muslin bag filled with the dried flowers of the hop (*Humulus lupulus*), probably owed any reputation it ever had to its coolness and the suggested purpose of its use rather than to any direct narcotic influence of the odour of the flowers themselves. It is said to have been first used to woo sleep for a merry monarch now departed—Bacchus on a hop-pillow, not crowned in boisterous mirth with the more graceful leaf of the vine! What a falling off was there!

As night is the normal period for sleep it is well when that function is disturbed to secure darkness in the bedroom by blinds of a sombre hue. This is the more especially desirable because the insomniac, after tossing restlessly the greater part of the night, frequently falls asleep towards morning, and his slumber is more likely to be resumed, if, in a moment of wakefulness, he open his eyes upon darkness, rather than upon daylight with all its associated duties. In the case of nervous children, however, who dread darkness, it is frequently necessary to keep some shaded light in their rooms when first put to bed. But this luxury should be withdrawn as they grow older, to inculcate that mood which they will find invaluable in after life—namely, fearlessness under all circumstances. For the rest it need only be added that the insomniac should be enjoined to impose the calm of natural sleep on his *voluntary* muscular system and to resist the temptation to tossing and restlessness. Voluntary muscular quiescence affords in itself a measure of refreshment. Patients have frequently been advised to pursue some monotonous imaginative exercise like counting sheep jumping over a wall, but the less voluntary exertion there is imposed either on brain or muscle, the sooner as a rule will sleep ensue. Patients should especially be impressed with the fact that sleep will overtake *them*, but they will only postpone its advent by endeavouring to overtake *it*.

FIG. 1.

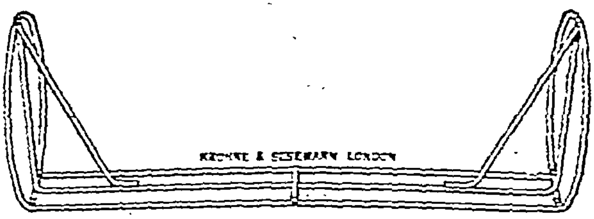

FIG. 2.

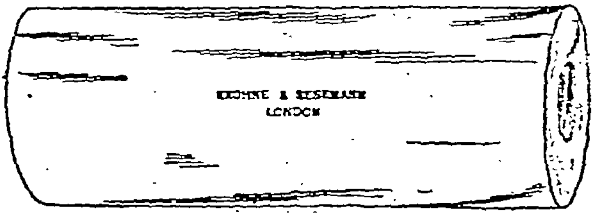

When sleeplessness is due primarily to *discoverable* physical causes, acting through afferent neural channels directly, or to causes acting indirectly as excitants to consciousness by conveyance to the centre in the blood stream, or, again, to such effects of these causes as disturbance of temperature or vaso-innervation, the removal or mitigation of such causes of defective sleep is necessarily the first duty of the physician. To enter with detail into this aspect of the treatment of sleeplessness would manifestly be out of place on this occasion, as it would require many lectures to deal with it adequately. It is therefore only possible in this connexion at present to indicate the principle of the removal of the ostensible cause of the sleeplessness in any given case to secure the disappearance of the effects in most instances. But even when such a procedure is in progress, be it temperature reduction, or the reduction or increase of vascular tension, or the treatment of any other abnormality whatsoever, it may be necessary to act directly upon the organ of consciousness, to secure sleep in that interval which must necessarily elapse in many cases before the introduced hæmic or the peripheral cause of disturbance can be eliminated. For this reason medicinal agents are necessary and their selection is not an unimportant detail.

Many as have been the hypnotics introduced into practice during recent years, when physical pain or disorders of visceral motion and sensibility are the active causes of insomnia, none of these has an efficacy in any way comparable to that of those oldest of hypnotics, opium and its derivatives. No agents, however, are more apt to induce the drug habit. Prescribed in the first instance for sufficient

TABLE I.—*Showing the Severity of the Eruption and the Age in 1824 Unvaccinated Cases of Small-pox.*

Class.	Age-periods—Years.								Total.
	0–5	5–10	10–15	15–20	0–30	30–40	4 –50	Over 50	
I.	43	18	12	7	10	6	4	3	103
II.	37	20	32	22	27	7	3	0	148
III.	137	132	91	73	62	29	8	5	537
IV.	123	112	64	30	38	15	3	1	386
V.	130	102	57	27	30	8	0	3	357
VI.	108	85	44	21	23	6	1	5	293
Total ...	578	469	300	180	190	71	19	17	1824

Class I. is hæmorrhagic small-pox. Classes II. and III. are confluent cases, the former confluent before pustulation occurs and the latter after. Class IV. is discrete small-pox with over 500 pocks on the face. Class V. is discrete small-pox with from 100 to 500 pocks on the face. Class VI. is small-pox with less than 100 pocks on the face.

It will be seen that the figures in this table show no preponderance of severe eruptions at early ages or at the very late ages of life when the death-rate is very high. On the contrary, with one exception (Class I., in infancy) the preponderance is slight but significant in the opposite direction—viz., increased number of pocks at increased ages.

Table II. shows the distribution that would correspond to complete equality of severity at all ages, which is calculated thus. Take the total number of cases in the first column—i.e., 578—and divide them up in the same proportion as the grand total 1824 in the last column is divided between the separate classes. Repeat the process similarly for every column. Table III. shows the difference between Table II. and Table I. It will be noticed that the differences are not great, but all the positive quantities tend to collect in the upper right hand and lower left hand quadrants, showing a slight preponderance of severe cases at higher ages.

The difference between any figure in Table I. and that which corresponds to it in Table II. represents the tendency that small-pox of a definite type has to attack persons of a definite age *in excess or defect of the average rate of all ages.*

TABLE II.

Class.	Age-periods—Years.								Total.
	0–5	5–10	10–15	15–20	20–30	30–40	40–50	Over 50	
I.	32·6	26·5	16·9	10·2	10·7	4·0	1·1	1·0	103·0
II.	46 9	38·1	24·3	14·6	15·4	5 8	1·5	1·4	148·0
III.	170·2	138·1	88·3	53 0	55 9	20 9	5·6	5·0	537·0
IV.	122·3	99·3	63·5	38·1	40 2	15·0	4·0	3·6	386 0
V.	113·1	91·8	58·7	35·2	37·2	13 9	3·7	3·3	356·9
VI.	92·8	75 3	48·2	28·9	30·5	11·4	3·1	2·7	292·9
Total ...	577·9	469·1	299·9	180·0	189·9	71·0	19·0	17·0	183·8

Table III. gives these differences, a + sign denoting that the observed number exceeds that calculated from the average, a – sign that it falls short. To avoid confusion fractions are omitted and the nearest whole number is given. In a few instances the difference is less than ½, so that the nearest whole number is 0. The + or – sign of the fraction is, however, retained.

TABLE III.

Class.	Age-periods—Years.								Total.
	0–5	5–10	10–15	15–20	20–30	30–40	40–50	Over 50	
I.	+10	– 8	– 5	– 3	– 1	+ 2	+ 3	+ 2	0
II.	–10	–18	+ 8	+ 7	+12	+ 1	+ 1	– 1	0
III.	–33	– 6	+ 3	+20	+ 6	+ 8	+ 2	– 0	0

The black lines divide the table into four quadrants. The top left-hand quadrant—i.e., cases of severe small-pox in young patients—and the bottom right hand quadrant—i.e., mild small-pox in old patients—both show deficiencies, while an excess of cases shows in the reverse conditions, viz., mild cases in young people and severe cases in old people.

ninistrations is likely to relapse at the first serious *contre-emps* unless lifted on to a higher level of open-eyed endurance, the road to which does *not* lie through hypnotism. On the therapeutic value in nervous disorders of indifference—*insouciance*—the readiness to meet with *sang-froid* whate'er betide, a not uninstructive essay might be written. It is a mood akin to, though not identical with, the grand attitude of Renunciation or *Entsagung* and both, born of strength, beget calm, and in the absence of organic disease, the normal consequences of that state, sound and refreshing sleep.

A Lecture

ON

SOME OF THE SOURCES OF WOUND INFECTION.

Delivered at St. Bartholomew's Hospital on Dec. 11th, 1907,

BY C. B. LOCKWOOD, F.R.C.S. ENG.,

SURGEON TO THE HOSPITAL.

GENTLEMEN,—You may have observed that twice a week in the operating theatre we make certain tests of the materials which we are using, of the hands which are brought into contact with the patient, and of the patient's skin. It is now some years since I last referred to this subject, and it is rather strange that I have never yet told you the reasons for my procedures. The essential object of making bacteriological tests during the performance of the operation is to ascertain the absence of bacteria. If bacteria are absent we then consider that we are working aseptically and we call the result asepsis. I am quite aware that that is not the sense in which the word asepsis is always used. Some surgeons apply the term to operations which are conducted by means of heat and with the aid of salt solution and without any stronger chemicals. Whether their results are clinically better than the results of surgeons who use mild chemicals I cannot say. But their published records show, I believe, that their results are never germ-free, and that in the vicinity of the wounds the staphylococcus epidermidis albus (the ordinary skin coccus) is continually present. The staphylococcus pyogenes aureus is not infrequent, and streptococci and even the colon bacillus are found. Now, I myself could not be contented with the presence of such micro-organisms in the vicinity of wounds. Besides, let us take what is after all a perfectly logical and scientific standard of excellence, the entire absence of bacteria, and then you know exactly where you are. At all events, a wound which contains no bacteria cannot be septic. What sepsis is I cannot tell you. It has never been defined. I should suspect that some of the wounds which contain streptococci, staphylococcus pyogenes aureus, or the colon bacillus may be very septic indeed.

The tests which we apply prove that everything which can be treated by heat gives perfectly aseptic results. Perhaps I ought to make this qualification and say that unless you steadfastly test—and I have been testing for more than 15 years—curious errors creep in. I remember a while ago being rather surprised when informed that the needles infected our broth. As soon as this was ascertained and brought to the notice of those who performed the process of sterilisation the needles were sterile. So, clearly, you must not assume the sterility of anything until it has been tested. In passing I would perhaps answer a question which has occurred to you, and it is this: Why might chemicals not be used for the disinfection of instruments? I have often wondered whether instruments dipped in pure carbolic acid are liable to infect. I am inclined to think that they may. Pure carbolic acid may coagulate albumin on the instruments and there may be infection beneath its layers and during the course of the operation the layer may come off and the wound may be infected. Mr. B. T. Lang very kindly tried to ascertain whether he could disinfect instruments by means of strong solutions of formalin. Formalin is a very potent disinfectant. A disinfectant is a chemical which kills bacteria. So Mr. Lang applied a 25 per cent. solution of formalin to infected instruments for 24 hours and had to acknowledge that he failed. Clearly, great caution is required before using instruments which you have attempted to disinfect by means of chemicals. I have said already that the effects of heat are absolutely certain. We have seen that over and over again. We are continually disinfecting silk by means of heat. It never comes into contact with any chemical whatever and is passed straight into broth but nothing grows. I want to make this qualification. Outside this hospital we have a hay market, and some years ago Dr. E. Klein pointed out that it was difficult, in experiments performed upon this site, to exclude the hay bacillus. And we have found that when any source of error has crept in the presence of the hay bacillus has been recorded. I need hardly say that the hay bacillus is a perfectly harmless bacterium, and one which is very easily recognised.

A far more potent source of wound infection is the skin of the human hand. When first I began to put a piece of skin from my own hand into broth an aseptic result was almost unknown. I became quite disheartened and thought it impossible to achieve asepsis. By making further efforts, and more especially by realising the value of alcohol, especially in conjunction with such antiseptics as the so-called biniodide of mercury, we began by degrees to achieve better results. I do not think that the inexperienced will ever get good results at all. I have been working at disinfection of the hands for over 15 years and am only now beginning to realise how difficult the problem is. I need hardly say that it is impossible in the preparation of the hands to disinfect or to clean beneath the angles of the nails; the nails must be cut off short. Next, it would be absolutely impossible to disinfect hands which have any open sore or septic place upon them. A new cut would not, I imagine, matter, but it would be unjustifiable to operate if there were any septic focus upon the hands. And, without going far out of my way, I could tell you of some dreadful disasters which have happened through the breach of this rule. You might think that if you had a septic sore upon your hands it would be justifiable to cover it up with, say, collodion or perhaps with a rubber finger stall or with rubber gloves. But I am afraid that that would not be right. Collodion comes off, finger stalls come off, gloves may have holes in them, and, further than that, gloves are often punctured during the course of an operation or may even be torn. So that a person with septic sores upon the hands should not perform surgical operations, or, what is equally important, gynæcological operations, including midwifery.

Supposing that the hands have been prepared for disinfection, that they have been cleansed as far as possible by means of soap and water, and freed from any superficial contamination, the next step is to disinfect the skin. Now that is really a most difficult problem. I have already told you that at one time we never achieved it. Then our results improved and we managed to disinfect perhaps once in five or six times. Then we have managed to improve and to disinfect 20 per cent. and then more. And on looking over the reports of the gentlemen who have so kindly taken cultures from my own skin I find in the last 66 tests that they have only caught me out once. As you know, this test is made with a small piece of skin snipped off and dropped into broth. Presently I shall tell you about more rigorous tests which we applied. I knew that various observers had examined the skin of their hands after they had been prepared with salts of mercury, such as sublimate or biniodide, and so forth, but usually sublimate, and that they had found that the skin after disinfection contained an appreciable quantity of mercury. Haegler in his book on the Disinfection of the Skin, which consists of 250 pages and four pages of figures, has made the same observation. After the hands had been prepared, treated with alcohol, and then soaked in sublimate he dipped them in a solution of sulphide of ammonium. Hands which had been treated with mercury came out black, proving conclusively that the skin retained within it a proportion of the sublimate. I snipped off some particles of skin from my own hands and sent them to Dr. W. H. Hurtley who with great kindness undertook to report upon their chemical properties. And he reported that the scraps from the freshly prepared hands contained an appreciable quantity of mercury. But Dr. Hurtley did not know until I told him yesterday that I had not for 27 hours applied any biniodide to some of the skin which I sent to him, so that the skin of my fingers had retained an appreciable quantity of mercury for that length of time and of course during that 27 hours they had been washed many times in the ordinary manner. So it is possible to saturate the human skin with mercury. On thinking this matter over it occurred to me that the

TABLE VII.—*Rash and Age.*

Years of age.	Rash.				Total.
	Faint.	Ordinary.	Marked.	Vivid.	
0–1	—	—	—	—	—
1	—	1	1	1	3
2	6	1	1	—	8
3	4	3	1	4	12
4	5	7	1	1	14
5	4	5	1	1	11
6	3	8	2	1	14
7	4	7	1	—	12
8	2	3	—	1	6
9	—	4	1	—	5
10	1	—	—	1	2
11	1	2	—	1	4
12	—	2	2	—	4
13	—	1	—	—	1
14	—	—	1	—	1
15	—	—	—	—	—
16–17	1	1	—	1	3
Total	31	45	12	12	100

We cannot, as in Table V., calculate the mean severity of rash for given ages, as our divisions are not quantitative, but it is possible to examine the table by working out the mean ages for given severity of rash, and we obtain:—

Rash, faint	Mean age,	5·76 years.
„ ordinary	„	7·23 „
„ marked	„	7·42 „
„ vivid	„	6·58 „

A more satisfactory method is to group the whole 100 cases in only four divisions retaining two age-periods, 0–5 and 6–16, and two grades of rash, faint or ordinary and marked or vivid. We get the following:—

TABLE VII.A.—*Rash and Age.*

Years of age.	Rash.		Total.
	Mild.	Severe.	
0–5	36	12	48
6–16	40	12	52
Total	76	24	100

Mere inspection shows that the agreement between the facts and the hypothesis of complete independence of age and severity of rash is as close as could be expected with 100 cases; but we can calculate the degree of dependence as follows: multiply the figures in opposite quadrants together, then take the ratio of the difference of these two products to their sum. This formula, called Yule's coefficient,[2] gives—

$$\frac{40 \times 12 - 36 \times 12}{40 \times 12 + 36 \times 12} = 0{\cdot}052$$

Pearson has given *formulæ for four-fold divisions, such as the above, which are probably more correct on theoretical grounds, but are much more tedious to calculate. In the* above case Pearson's formulæ give—

$$r = 0{\cdot}039.$$

The connexion is between high age and mild rash, but is so slight as to be negligible. We can examine throat severity in a similar way. The notes on this gave five natural classes, clean throats, either red or red and swollen, and dirty throats, with slight, moderate, or much deposit. *In the following* table only four divisions have been used.

TABLE VIII.—*Throat Lesion and Age.*

Years of age.	Throat.				Total.
	Clean.	Dirty.			
		Slight.	Moderate.	Severe.	
0–1	—	—	—	—	—
1	3	—	—	—	3
2	6	—	1	1	8
3	6	1	3	2	12
4	11	1	1	1	14
5	8	1	2	—	11
6	10	2	1	1	14
7	9	—	3	—	12
8	2	—	3	1	6
9	5	—	—	—	5
10	1	1	—	—	2
11	2	—	1	1	4
12	3	—	1	—	4
13	1	—	—	—	1
14	1	—	—	—	1
15	—	—	—	—	—
16	3	—	—	—	3
Total	71	6	16	7	100

TABLE VIII.A.—*Throat Lesion and Age.*

Years of age.	Throat.		Total.
	Clean.	Dirty.	
0–5	34	14	48
6–16	37	15	52
Total	71	29	100

$$\text{Yule's coefficient} = \frac{34\times15 - 37\times14}{34\times15 + 37\times14} = -\ 0{\cdot}008$$

$$\text{Pearson's} \quad „ \quad = -\ 0{\cdot}006$$

The correlation is thus even less than in the last instance. The negative sign means that high age is associated with mild throat lesion *though only to an insignificant extent.*

As a contrast to Tables VII. and VIII. the following two show a high association between severity of throat lesion and rash respectively and severity of fever, and the next a moderate association between the two former factors.

TABLE IX.—*Rash and Maximum Temperature.*

Maximum temperature.	Rash.				Total.
	Faint.	Ordinary.	Marked.	Vivid.	
98°–99°	3	—	—	—	
99°	6	6	1	—	13
100°	11	14	1	1	27
101°	1	7	3	1	12
102°	5	6	4	3	18
103°	4	10	3	5	22
104°–105°	1	2	—	2	5
Total	31	45	12	12	100

In Table XI. the correlation *is* rather irregular, that is, there is a higher *proportion* of clean to dirty throats in the middle row than in either the top or bottom row. Accordingly, we do not fairly represent the facts by condensing either the two top or two bottom rows to make the division fourfold. A fair result can be obtained either by working out both methods and taking the mean or by splitting the middle row into two halves to get a *fourfold table. By the latter* method I have calculated Yule's coefficient as $+\ 0{\cdot}146$. The source of this environment infection. First of all, the condition of the atmosphere would, of course, depend upon the size of the room. The room we are in is a very suitable size for an operating theatre. It contains about 9000 cubic feet. The small operating theatres contain from 5000 to 7000 cubic feet, and the old operating theatre contains some 12,000 cubic feet. The new theatre at the top of the east block is a very good size for a theatre and contains about 9000 cubic feet. I wonder if I am making any impression upon your minds. Some of you gentlemen will have to plan operating theatres, and this question of size will be one of extreme importance to you. The next thing about the atmosphere of an operating theatre is this. If you agree that you are going to have 10,000 cubic feet of space in your operating theatre how often ought that air to be changed for the comfort of the inmates? It is agreed by those who are versed in the science of ventilation that the air ought to be changed at least six times in the hour. In the building you are in at present they have instituted a modified form of the Plenum system of ventilation. That system does this, it takes air in from the outside. And that air is filtered and moistened. It is then passed over water-pipes to warm it in winter to 65° F. and cool it in summer, and then it is passed to where it is wanted. The vitiated air goes out at the top. I may tell you that I have no prejudice in this matter. The proper Plenum system necessitates the closure of doors and windows. But the Plenum system occasionally breaks down. I believe it broke down the other day at the new law courts with very unpleasant results. Again, I am told that the people living where that system is in operation do not feel comfortable and that children who live in it become anæmic. These are not my own experience; they are simply what I have been told. Against that you have to put what is known as the natural system. That admits air near the floor beneath radiators, and then it has an extractor consisting of a fan near the roof for the vitiated air. The theatre we are in has, in addition to these appliances, a Tobin's tube. My experience of these tubes is unpleasant, because the air enters half-way up the room and is often cold and falls down on to the top of one's head, and so is uncomfortable if you sit near it. What I want to impress upon you is that you have to make up your minds about the size of the operating theatre in which you work and decide how often the air ought to be changed, and next the method by which it is to be changed. Besides odour and unpleasantness, what other tests are there of the condition atmospheric? There is the bacteriological test. I can tell you offhand that in great cities air outside the windows contains various sorts of bacteria which are derived, of course, from the animals in the streets, from the surface of the bodies of the people who are walking about in the streets, from their respiratory tracts, and so on. I can tell you further that in a room such as this all those bacterial contaminations are increased. And they are increased in many ways. At present, whilst I am speaking to you in an ordinary colloquial manner, it has been scientifically shown that I am not sending my throat or mouth bacteria into the atmosphere. This work was begun by Flügge, but in the last few years Dr. M. H. Gordon has added most important scientific evidence and has extended the work by identifying the bacteria. He says that as long as a person speaks in an ordinary conversational tone nothing is emitted from his throat into the air around. But as soon as he begins to speak loudly and to gesticulate, then bacteria are showered to a distance of 40 feet from the mouth. Therefore the mouth is a potent source of infection of the atmosphere. What happens in that respect when a person coughs and sneezes it is difficult to imagine, but if loud talking and gesticulating will send bacteria 40 feet, I assume that coughing and sneezing will send them 20 or 30 more. Another potent source of aerial contamination is dust and dirt brought in upon the garments and boots of people from the street. The carrying of bacteria upon the boots is not a matter of speculation. That might be guessed when one thinks what a horrible mixture the mud in the roads is, that there may be colon bacilli in it, streptococci of various kinds, the tetanus bacillus, the bacillus septicus, tubercle bacilli, and many others. It is certain these may, when present, be carried into theatres on people's boots, because Dr. Gordon made the following experiment. At the House of Commons he put down some earth which had been contaminated with the bacillus prodigiosus, a bacillus which it is very easy to identify. He then examined the dust which fell from beneath the gratings where the Members of the House of Commons trod, and he found that they carried the *bacillus prodigiosus* on their feet a distance of 576 feet. You can therefore very well imagine the dangers of this form of infection. How is that to be met? One of the great ways in which anything is met is not by laying down rules but by educating people. And no man who had ever thought of this would willingly carry dirt or dust into rooms or operating theatres, nor would he, when he got there, stamp about the dust which is there. But, after all, there is a great deal of human nature in man, and human nature dictates that he will not always remember. In consequence of that steps ought to be taken—and we are taking them—to provide a cheap and efficient method of covering up dirty boots before they go into the theatres. But in addition a glass screen should be placed between the audience and the operator. The glass screen need not go up to the top of the theatre; it would become, perhaps, in such circumstances easily clouded with moisture and the audience would not be able to listen to the dulcet tones of the operator.

---

[2] With both Yule's and *Pearson's formulæ* 1 would represent perfect correlation—i.e., that for every age there occurred only one fixed type of rash—and 0 would represent no correlation—i.e., that various types of rash occurred indiscriminately at all ages, which is *practically* what does occur.

I have only mentioned some of the matters on which we are engaged, but have perhaps told you enough to interest you in what we are doing, and I hope shall encourage gentlemen to take these matters in hand and try to go one better.

IS THE DEATH-RATE THE BEST MEASURE OF SEVERITY IN DISEASE?

By F. M. TURNER, M.D. CANTAB., B.SC. LOND.,
MEDICAL SUPERINTENDENT OF THE SOUTH-EASTERN FEVER HOSPITAL, NEW CROSS, LONDON, S.E.

LONG habit has made many medical men so familiar with the use of death-rates (or, to use the stricter terminology, of case mortality rates) that they have come to regard them as *the only* possible measure of severity in disease. Others would not deny that other means of measuring severity might be used, but would emphatically deny that the latter could in any case give results more accurate than those given by mortality rates. To measure severity by any other criterion than recovery or death they might admit to be possible, but if the special method gave results *opposed to* those given by mortality rates such discrepancy would prove, they consider, the unreliability of the former. This exaltation of mortality rates into an absolute standard is quite unjustifiable. And, what is of more practical importance, a devotion to mortality rates as the chief, if not the only, subject worthy of study in medical statistics accounts in great measure for the present backward state of that branch of science. In the present paper I hope to show by very simple methods, first, that reliance on mortality rates can mislead; and, second, that the mortality test can for many problems be a very inconvenient one and much less likely to give the true solution than other methods.

I. *The mortality rate is not in all cases a reliable test of severity of disease.*—The first thesis will be proved if I can show that the mortality rate can be affected by other circumstances than the severity of the disease. It is often suggested that death or recovery may depend upon two independent factors: (*a*) the severity of the attack and (*b*) the strength of the patient; and although many will be prepared to admit both factors as possibilities they have no clear idea how the effect of these factors could be distinguished. How can we measure the vitality of our patients? Some would hold that it is not measurable, others would argue that whether such patients die or recover must be the true test. And how can we measure the severity of attack unless we here also fall back on the mortality rate? The answer is very simple. We can in many cases measure the symptoms, and, if so, we have a real test of the *severity of the disease*. And even if the symptoms are not measurable we can still get reliable results if we divide cases into groups or classes according to the *severity of any symptom*.

The first example which I will give is a table which I published in the reports of the Metropolitan Asylums Board for the year 1904, showing the connexion between the age of the patient and the severity of the eruption in cases of small-pox amongst the unvaccinated. For the facts I am indebted to Dr. T. F. Ricketts, medical superintendent of the Metropolitan Asylums Board small-pox hospitals.

death-rates is 1·24 and is not much larger than the probable error, which is 0·92. Such a difference might therefore very often arise as a chance effect. The severity of the cases, however, lends itself to measurement in many other ways, two of which I have used in attacking this problem. Classified according to duration of pyrexia the 78 cases caught in hospital were grouped as follows :—

Duration in days	0	1	2	3	4	5	6	7	8	9	10	11
Number of cases	4	8	10	20	9	7	3	4	2	1	1	2
Days (*continued*)	12	13	14	15	16	17	18	19	20	21	22	
Cases (*continued*)	1	2	—	1	—	1	—	—	1	—	1	

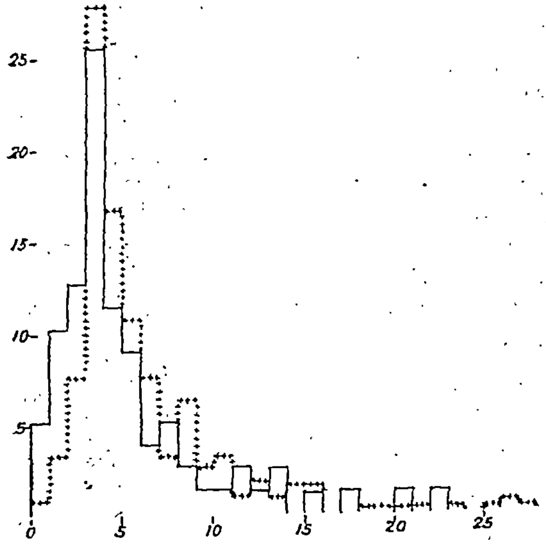
Giving a total of 78 cases.

A series of 314 ordinary cases all admitted on the first or second day of disease gave the following :—

Duration in days ...	0	1	2	3	4	5	6	7	8	9	10	11	12	13
Number of cases ...	2	10	24	88	53	34	24	10	20	8	10	3	6	3
Days (*continued*) ...	14	15	16	17	18	19	20	21	22	23	24	25	26	27
Cases (*continued*) ...	5	5	—	—	1	1	1	1	—	1	—	1	2	1

Giving a total of 314 cases.

The two series, reduced to percentages in each case, are shown together on the annexed chart, where the vertical line of figures shows the number of cases per cent. and the horizontal line of figures the duration of fever in days.



Cases caught in hospital shown by continuous line, other cases by dotted line.

The mean of the first series—i.e., cases contracted in hospital—is 4·05 ± 0·29 and of the second series is 5·05 ± 0·16. The difference in mean duration is therefore one day. The probable error of this difference being only 0·33, or one-third, it is unlikely that another series of cases taken in similar circumstances would give a different result.

The cases were also grouped according to the maximum temperature recorded, or culminating point of the fever, with the following results :—

Culmination of fever ...	98°	99°	100°	101°	102°	103°	104°
Number of cases	4	6	8	23	23	11	3

Giving a total of 78 cases.

A series of 679 ordinary cases similarly grouped gave the following :—

Culmination of fever	98°	99°	100°	101°	102°	103°	104°	105°
Number of cases ...	162		131	157	128	90	10	1

Giving a total of 679 cases.

The mean of the first series is 101·795 ± 0·10 and of the second series 101·167 ± 0·037 and the difference is 0·63 ± 0·11 degrees. Summarising the above evidence, cases of scarlet fever caught in hospital tend to have higher fever, which, however, does not last so long. The death-rate also appears to be less. The first two conclusions are, however, almost certain; the third is well within the limits of chance error.

A second problem of considerable practical importance is the *dosage of antitoxin in diphtheria.* In spite of the elaborate reports issued during the early years after the introduction of antitoxin into this country the proper scale of dosage remains still very uncertain; and I think the current doctrine on the subject consists more of *ex cathedrâ* statements than of proved facts. Quite recently the medical superintendents of the Metropolitan Asylums Board discussed this matter and a considerable divergence of opinion was shown. Surely the problem is capable of solution, but not if we rely on the death-rate as the only fact worth observing. Even if two hospitals be compared, each treating 500 or more cases a year, and one hospital employing on an average double the dosage of the other, I doubt if any differences observed in the death-rates would convince anybody. The advocates of the system which showed the higher death-rate would assume that the rival hospital got a larger proportion of mild cases. Our obvious duty, therefore, is to devise some method other than the death-rate for measuring the severity of cases, and if clinical observers set themselves seriously to this task I see every reason for believing that almost all problems connected with the efficacy of treatment of common diseases could be solved, say, within one or two years of their being propounded.

New Cross, S.E.

EXCISION OF THE RECTUM FOR CARCINOMA.

BY W. ARBUTHNOT LANE, F.R.C.S. ENG.,
SURGEON TO GUY'S HOSPITAL AND SENIOR SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

THE risk associated with the operation of complete removal of the rectum and of all infected mesenteric glands is so considerable that I have made many attempts to minimise it by modifying my operative procedures. I am not referring to such measures as that known as Kraske's operation which, in my opinion, is unsatisfactory for many reasons. The operation that I have adopted for some time appears to me to effect the maximum of benefit to the patient with a minimum of risk and discomfort. The last feature—namely, the absence of discomfort—is of paramount importance inasmuch as the sufferer is already sufficiently depressed by the very serious nature of his malady. I only apply this procedure to cases in which it is not possible to resect a portion of the bowel to establish continuity. I make use of it in cases in which it is advisable to remove the growth and all infected tissues, and when the patient is prepared to accept the very trifling inconvenience of a colotomy in the immediate vicinity of the middle line in the substance of the rectus. The younger the patient the more necessary is it that a very radical operation should be performed. The principle involved in this operation is the separation of the peritoneal space contained in the true pelvis with the diseased portion of the intestine from the general peritoneal cavity. This prevents any chance of a general infective peritonitis when the rectum is removed from below and obviates the formation of adhesions involving the small intestines, since no raw surfaces are left in the pelvis to which the bowel can become attached.

The procedure is as follows. A vertical incision is made three-quarters of an inch to the left of the middle line from the umbilicus *downwards for about four inches.* The opening is formed in this situation as it affords easy access to the pelvis and to the sigmoid flexure. In these cases the sigmoid flexure is almost always pinned down by adhesions. These are of the same nature and perform the same function of obliterating the loop as in obstruction due to constipation. A further reason is that in this situation a firm scar can be obtained in which the rectus muscle controls more or less completely the exit of material from the bowel. The patient being placed in the Trendelenburg position and the pelvic cavity being rendered *fully accessible* by the use of suitable retractors, the growth is carefully

A stronger preponderance of severe cases among the older patients is shown if we take the vaccinated cases; though the effect of vaccination in infancy and the gradual disappearance of the protection afforded by it render the table less suitable to the illustration of my thesis. To save space the numbers corresponding to equal severity at all ages and the differences between these and the actual figures have been entered in the same table.

A second instance is obtained from a paper, not yet published, by Dr. W. Lowson and myself on the temperature in scarlet fever. Here we have measured the severity of pyrexia in each case by measuring the area included on the temperature charts between the record of the patient's temperature and the normal line. For the precautions taken I shall have to refer my readers to the paper when it appears.

TABLE V.—*Temperature—i.e., Area on Temperature Chart.*

Years of age.	Area of fever shown on chart.								Total.
	0–5	5–10	10–15	15–20	20–30	30–50	50–100	Over 100	
0–1	1	—	—	—	1	—	1	—	3
1	15	2	3	1	—	3	4	1	29
2	27	5	1	1	4	—	1	2	41
3	25	1	4	2	2	4	4	1	43
4	25	12	3	1	5	1	4	1	52
5	13	4	3	1	2	5	1	2	31
6	18	1	4	3	2	5	1	—	34
7	11	1	2	1	4	1	—	—	20
8	4	1	—	—	1	2	1	1	10
9–10	3	2	—	—	—	1	2	—	8
10–15	8	8	7	5	5	4	1	1	39
15–20	3	2	1	—	2	—	1	—	9
Over 20	1	—	—	1	2	1	1	—	6
Total ...	154	39	26	16	30	27	22	9	325

Thus the top line shows that out of 325 cases of scarlet fever only three were under one year of age, and that of these one had very slight pyrexia, an area of less than five units—i.e., 0·5 of a square inch on the charts used. The other two had more severe attacks with areas of over two and over five square inches respectively.

In the first example we could not calculate the mean severity of eruption, since our six classes were not quantitative, and we had to fall back upon a less familiar way of attacking the problem. But in this example area is a measurable quantity, and we can accordingly find the mean area (i.e., the mean severity of fever) for each age-period. The results are as follows:—

Years of Age.	Mean area of temperature chart.
0–1	34·1
1	28·8
2	14·9
3	18·9
4	15·8
5	23·9
6	28·6
7	10·9
8	34·7
9–10...	26·5
10–15...	14·6
15–20...	12·7
Over 20	31·6
All ages	19·2

Though the numbers at different ages differ considerably, it will be noticed that those means, based on considerable numbers of cases, cluster fairly closely round the mean of the whole and that the most discrepant values are based upon a small number of cases; also that there is no tendency for high ages to be associated with low values of area. In other words, the differences found are probably due to chance. A more satisfactory calculation can be made by using formulæ which apply to the figure as a whole—viz., those introduced by Bravais and Pearson. By them I have obtained the value of the correlation coefficient of the table[1]—

$$r = +\,0{\cdot}0072 + 0{\cdot}038.$$

These figures may be interpreted thus: The correlation between age and severity of fever in the 325 cases investigated is positive, showing a greater severity at greater ages. In magnitude, however, it is extremely small, and if another 325 cases were examined the laws of probability would lead us to expect the discrepancy between the two series to be about five times as great. In other words the table shows, as clearly as can be shown with the number of cases investigated, complete independence of age and severity of fever.

We have now two instances, one in small-pox and another in scarlet fever, of independence, or at least almost complete independence, of severity of symptoms with age of the patient. In both cases, however, the mortality-rate shows a very great alteration with age, as shown below:—

TABLE VI.—*Mortality Per Cent. at Different Ages in Scarlet Fever and Small pox.*

—	Age-periods—Years.								
	0–5	5–10	10–15	15–20	20–30	30–40	40–50	Over 50	All ages
Small-pox, unvaccinated cases	48·3	18·0	23·1	25·1	35·5	48·1	75·0	55·5	33·2
Scarlet fever	6·09	1·68	1·44	0·63	1·90	0·71			3·26

If the quinquennium 0–5 be subdivided the variation with age becomes still more striking. The conclusion seems obvious that in these two diseases the great variation of mortality with age depends solely upon the vitality of the patient and is independent of the severity of the disease. Only one means of escape from this conclusion, which I confess was quite unexpected by myself when I started to collect the facts, seems possible; and I have no doubt that some critics will avail themselves of it.

We have taken in each disease one symptom only as criterion of severity. Is this justifiable? Does not the mortality test sum up all the phenomena of the disease in a perfect manner, so that the mere use of a single symptom is comparatively unreliable? To this objection the proper answer would be to take the various symptoms in order and see whether the high death-rate in early childhood could be ascribed to any of them. In small-pox this course was not possible for me; and in scarlet fever for a long time I considered that the facts could only be ascertained after a vast amount of labour, such as might take many years to carry out. For instance, the severity of scarlet fever rashes might be estimated by comparing the colour of the patient's skin with a set of standard shades of red and crimson. But it would take some time to get several observers used to working with these, and a further period for the collection and reduction of the observations. Only recently did it occur to me that for our present purpose such a high standard of accuracy is not required. The published statistics of fever hospitals show year by year that the mortality of scarlet fever in patients under two years of age exceeds about ten times that of the disease at the prime of life, say from 10 to 25 years of age. The tables given above show that this excess mortality in infants is not due to an excessive severity of fever. If it were due to excessive severity of rash or of throat lesion we must have severe throats and rashes preponderating amongst the younger children to an extent that would show itself in the notes taken by ordinarily careful clinical observers, and special observations *ad hoc* are not necessary. I accordingly took 100 consecutive reports of cases from the bed-cards of the South-Eastern Hospital and wrote a special slip for each case, noting (1) the age; (2) the severity of the rash; (3) the duration of rash, if noted; (4) the severity of throat lesion; (5) the presence of complications; (6) the duration of fever; (7) the maximum height of fever; and (8) the result—i.e., death or recovery. From these slips it was possible by sorting to examine into the connexion between age and any of the other factors, or between any pair of the latter. In short, it was possible to compile 56 different correlation tables, out of which I publish the following as sufficient to show (*a*) that there is little or no correlation between age and severity of rash or throat lesion; but (*b*) that there is moderate or high correlation between certain other pairs, such as throat lesion and maximum height of fever, and rash and maximum height. The notes as to rash varied a little in terminology with different observers, but seemed to fall most naturally into four classes—faint, ordinary, marked, and vivid.

---

[1] The table given is abridged from that in Dr. Lowson's and my paper. The value given above was calculated from the full table.

various expedients of cruel and brutal nature are adopted. For instance, they may jump on the body of the woman as she lies upon the floor. They may try to seize any presenting part and tear at it, perhaps even pulling off the scalp of the child. They may tear the vulva and vagina or use knives in a senseless endeavour to make a way for the child. The woman may be made to sit over hot ashes and burning twigs or charcoal. When she is very far gone they may at last send for the medical missionary, who may find the patient severely burned or lacerated, bruised and bleeding. The bladder may be ruptured, the abdomen greatly distended, the patient pulseless and insensible. She may die before anything can be done or may expire immediately after delivery. If the burned cases survive the first shock they will very likely die from gangrene, or the whole of the vagina and bladder may slough, and tetanus is very common. After labour the patient is kept lying on the floor for three days without food or drink. The baby is given cow's milk at once, which upsets it. It is against their religious ideas to wash the child till the tenth day. A large proportion of the newly-born children die from tetanus. The mothers are considered to be unclean until the eighth day and are often kept outside of the house in a little shed, which is a dark room like a cupboard. After their first bath they are taken back into the house but if fever set in the bath of purification is delayed until they are well, if they do get well. If these women are treated rightly in childbirth their labours are as easy and normal as are those of women in England, probably more so on the average. When labour is delayed, or they desire to produce abortion, a powerful and irritant poisonous drug is sometimes administered, the nature of which is not known to us. It causes severe pain and green vomit and seems always to be fatal.

A second similar illustration is taken from the *New York Medical Record* for January, 1906, where Dr. W. D. Bell describes observations made during a residence of 13 months on the island of Luzon in the Philippines. He says that the so-called safety supposed to exist amongst savage peoples in childbirth was not found in these islands, for barbarous practices and tortures with far-reaching consequences were what were really observed. No attention was paid to the sanitary surroundings of the patient. As soon as the first real pains manifested themselves the patient was held on the ground and a cloth was passed around the abdomen and the four ends were pulled by four persons seated on the ground with their feet against her body. As soon as a portion of the child presented it was immediately seized by a fifth assistant and vigorously dragged upon, regardless of consequences. If any delay occurred a plank was laid across the abdomen on which a native assistant stood, raising himself on his toes and coming forcibly down on his heels. This was usually successful except in breech presentations, when a rude attempt at version was made with hands innocent of any effort to cleanse them. Few cases escaped laceration and sometimes the uterus was ruptured. If the same means failed to expel the placenta forcible traction was made on the cord and very often parts of the placenta were left behind, with the usual consequences. Prolapse, inversion, and puerperal sepsis were frequent here, also chronic endometritis. Syphilis and gonorrhœa were also common.

II.

The development of obstetrics falls into three stages. First, there is the *primitive stage*. This is characterised by the absence of all literature and of all knowledge of anatomy and physiology, and by an overwhelming amount of superstition, by the crudeness and absurdity of its ideas and the barbarity of its methods. It is almost without exception in the hands of women. In the second or *intermediate stage* we find the beginnings of obstetric literature and some attempt to describe the various positions of the fœtus in the womb and to lay down rules for treatment. The practice of midwifery is almost wholly in the hands of women, but men are called in in very bad cases to help. The treatises are written by men for the guidance of midwives. Version and embryotomy begin to be described but not forceps. The third or *scientific stage* may be said to begin about the time of Ambroise Paré in the sixteenth century, and its history has often been written. The intermediate stage has its dawn in the ancient Hindu physicians, such as Susruta, and there may even yet be recovered some of the lost literature of Egypt which will show more obstetric knowledge than we at present credit to those times. An account of their obstetric knowledge will be found in Mackay's "Ancient Gynæcology." Literature practically begins for us with the writings of Hippocrates and his followers in the fourth century B.C. Ancient obstetrics reached its high-water mark in the works of Soranus and his translator Moschion in the second century A.D. From this time it made very little advance till the time of Paré—in fact, there was decided retrogression during the middle ages.

Midwifery was in the primitive stage from the earliest times till the days when Greek learning made a bright spot in the general darkness, and it remained primitive throughout the centuries except where Greek, Roman, and Arabian medicine spread, and even here obstetric art was but too little removed from the realm of superstition and ignorance. It remains primitive to-day wherever Western science has not spread and forms a most interesting field for the study of the obstetrician and ethnologist. The human race has shown wonderfully little precocity in the practice of obstetrics. Nations who have perfected the arts of agriculture and of the chase, who have forged offensive and defensive weapons, built temples and palaces, woven textile fabrics, produced pottery, sculpture, poetry, and philosophy, have remained woefully ignorant of an art which, if necessity begets invention, might, one would think, have been one of the oldest and most advanced known to mankind. To some extent this may be due to the fact that the management of childbirth has been so very largely in the hands of women. The history of the race seems to show that all the mechanical arts have been developed not by women but by men. Obstetrics never began to develop till men took it from the exclusive practice of women, studied the mechanism of childbirth, and supplied the necessary mechanical aids. But man has no place in primitive obstetrics; uncivilised man would certainly decline to concern himself with such woman's affairs. She is regarded as an inferior being. As one writer says: "She is worth so little, so easily replaced; she is good for the bearing of children, to look after them, and to give satisfaction to her master, and especially to do the work of the field. As soon as she is a nuisance she is left, sold, killed, possibly eaten." It is certain that if scientific treatment were available but its cost exceeded the market value of the woman it would be refused. The birth of scientific midwifery coincided with the revival of learning, the introduction of printing, the Reformation, the discovery of the new world, and the introduction of inductive methods of research. The exalted estimate of the value of woman's life which the spirit of chivalry engendered prepared the way.

In studying this subject I have made use of Herrgott's French edition of Siebold's "History of Obstetrics" and also of the valuable historical sketch prefixed to Winckel's colossal "Handbuch der Geburtshülfe," but more especially of Ploss's ethnological monograph "Das Weib in der Natur- und Völkerkunde" (eighth edition, by Dr. Bartels, 1905). Also of Engelmann's "Labour amongst Primitive Peoples," and Mackay's "History of Ancient Gynæcology." There are various other papers scattered through the journals of the Anthropological Institute and elsewhere. An almost exhaustive bibliography will be found in Ploss, Vol. II.

The subject has two aspects. One is concerned with various rites, superstitions, and customs which have little or no direct bearing on the progress and welfare of the parturient woman, such as the various deities that have to be propitiated. These I pass by here. Secondly, there are various modes of practice (or malpractice) which bear directly on the obstetric management of the case and on the issue as regards mother and child. This attempt to give a concise, though by no means exhaustive, review of these will, I hope, interest those who may not have paid much attention to the subject. Perhaps this article may lead some readers of THE LANCET who have the opportunity of first-hand study of the practices referred to to add to our knowledge by recording personal observations, such as those which have already been given in this paper.

The question has been raised as to how far any obstetric art is necessary amongst uncivilised people. Are there not many of the primitive races where the process of parturition is so easy that difficulties and fatalities are rare? The answer gathered from Engelmann and Ploss seems to be that so long as the woman lives in a perfectly natural state, leading an active outdoor life and taking her share in manual toil, labour is usually short and easy and the process remains purely physiological and is only a rather difficult physiological evacuation. So that we find amongst nomadic

Severe	14	10	24
Total	71	29	100

correlation is much lower than in the two preceding instances, and being irregular must be regarded as not very certain. A larger number of cases or a more careful system of note-taking might, however, show it to be real.

The foregoing examples suffice to show that high correlations exist between certain pairs of symptoms in scarlet fever but not between age and either of the three most obvious of the symptoms in this disease—viz., rash, throat lesion, and pyrexia.

II. *The inconvenience of the mortality rate as a test of severity.*—Those who have followed the first part of this paper will probably have already thought of most of what I propose to say under the second heading. Nothing is commoner in medical discussions than to hear it said that certain problems ought to be settled by statistics, and yet hardly anything is rarer than to see these vexed questions actually argued out and settled by an appeal to the facts—i.e., statistically. Various problems no doubt occur to all, but those I allude to may roughly be classed into the effects of treatment and the effects of other factors in the environment. To take examples from my own specialty, medical men who treat scarlet fever differ in some details of treatment, such as the routine time for keeping the patient in bed, the treatment of the throat, the amount of diet allowed both in the acute stage and in subsequent nephritis. Apart from treatment, many other questions have been raised, some of them of great theoretical or practical interest. Do fever wards get more unhealthy with continued use? Are such complications as post-scarlatinal otitis and nephritis infectious? Is there any evil result from overcrowding in fever wards? What effect has poverty on severity of disease? Are there differences due to difference of race, as between aliens and natives?

In the Metropolitan Asylums Board hospitals, with an experience of 20,000 scarlet fever cases a year, one would think that ample material was available for settling in the course of a few months, or at most in a couple of years, every one of the above questions. Yet very few of them have even been seriously attempted and the results of the attempts so far made have not always been as conclusive as could be desired. And one important cause contributing to this has been the very low death-rate in scarlet fever. In the last published volume of the Metropolitan Asylums Board reports the death-rate for all hospitals was 2·94 per cent. That is to say, that in 1000 cases one would expect about 29 deaths. Time and opportunity rarely allow any careful experiment to be made on any much greater number than this, so we require to know what would be the difference from 29 deaths per 1000 which would convince us that our treatment had been improved or that any other change had really happened in the conditions. A knowledge of the laws of probability would teach us that not unless the deaths fell to 15 or 19 per 1000 should we have good reason for supposing that we had anything beyond a chance variation. A knowledge of the mathematical formulæ appropriate to the case is not very widespread among medical men, but there is an equivalent deeply ingrained in the minds of those who are most familiar with statistics. Those who see scarlet fever cases by the thousand are well aware that any reduction in case-mortality that can be hoped for by improved methods of treatment will be too slight to be shown conclusively by working with death-rates. Theoretically the difficulty could be overcome by working out a sufficiently extensive series of cases; in practice this is improbable. The difficulty of insuring uniformity of treatment (or other conditions) over 10,000 cases is very great and the time occupied in the experiment would probably cause disturbance in the results from the slow alteration in type that goes on from year to year. On the other hand, if we use other criteria of severity, as in some of the instances given above, it is easy to find a line that divides the cases into two approximately equal divisions. Here with only 100 cases it might be possible in some problems to get a decisive result, and where 1000 cases are available a definite answer to any statistical problem would be almost assured.

The only important argument in favour of death-rates and complication rates, as against criteria obtained by measuring the severity of symptoms, is the risk of high personal equations in the latter. The risk is not so great as most people assume. It is quite possible to choose criteria of severity that are little affected by it—e.g., the duration of fever or the area of a temperature chart. And even in other non-measurable characters the adoption of standard degrees of severity for the purpose of collecting observations would not be very difficult, if only observers were convinced that it was worth while.

A concrete case or two will make my meaning clearer. A problem of considerable theoretical interest is this. "Are cases of scarlet fever contracted inside a fever hospital more severe than those contracted in the usual way?" Since the reopening of my own hospital 18 months ago 78 such cases have occurred with only one death. The death-rate has therefore been 1·28 per cent. The death-rate usually met with in my own and kindred institutions is about 3 per cent. The last published figure for my own hospital on 1001 cases was 2·52. Taking the latter figure, the death-rate amongst the cases caught in hospital is less than half that found amongst ordinary cases, yet the evidence in favour of a change in severity is very inconclusive. It is by no means uncommon to get a run of 78 cases with only one death and the difference in the two series might easily be due to chance. Mathematically calculated, the difference of the back, or made on her back while she lies on her face, while a pillow may be placed under the abdomen. Felkin depicts a woman on her knees leaning over a log whilst a bandage round the abdomen is twisted with a stick like a tourniquet, the pressure being applied intermittently. 5. Pressure is sometimes applied by weights. Heavy weights are used by the Tartars in Astrakhan, great stones in Serang, and warm bricks with great pressure (Malays). In the Philippine Islands a beam or plank may be laid across the abdomen and assistants may sit or stand on this. A carved wooden idol of great weight is used in Siberia. 6. The woman may stand and compress her body against a bamboo or may lean over a horizontal pole or cord. These violent methods often result in internal injuries, such as rupture of the uterus and bladder and other viscera. 7. Shaking the woman in labour was much esteemed in ancient Greece as a method of expediting delivery. A cloth was passed around her and she was shaken violently at least ten times. Then they laid her in bed so that the head lay downwards and the feet upwards, and the assisting women, who held the legs of the patient placed on their shoulders, shook her repeatedly to and fro. Soranus was wise enough to condemn this. As examples of the same barbarous method amongst savage races take the following: raising and shaking the woman with a jerk, as in shaking flour out of a sack (Mexico); rolling on the ground and then suspending by the feet and shaking (Southern India); and rolling violently in a blanket by four people and shaking in all directions. The woman may be slung to the branch of a tree by a cord running under the arms, whilst a woman hangs around her waist (Coyotero-Apachen Indians); or a man will take the woman on his back and run about shaking her (North-West Russia). 8. Another strange practice is to invert the woman with the idea of altering the position of the child into a more favourable one when delivery is delayed. This was done amongst the ancient Greeks. It has been observed in Algeria. Also amongst some Indian tribes this is done repeatedly, and if it prove of no avail the midwife inserts her hand and pulls at anything she can reach. Fatal results follow this treatment. An instance of extreme barbarity is reported by Stern and quoted by Ploss as occurring in Persia. In extreme cases the woman is held head downwards with the legs fully abducted, and the kabli, with rusty scissors or kitchen knife, cuts the perineum mercilessly. If the woman bleeds severely it matters but little, although the midwife would be blamed if the child's arm or leg were severed.

The serious nature of a transverse presentation is widely recognised. It is obvious that where no obstetric science is known a cross-birth will almost always be fatal. Various nations have made attempts to rectify the position of the fœtus during pregnancy and here and there some have learned how to do it by external manipulation. The prevalence of massage may depend partly on this idea. Metzger, quoted by Ploss, is of opinion that the women in Damaraland, South Africa, have a successful method of performing cephalic version by external manipulation. The art is handed down from mother to daughter. Lübbert says that the natives of German South-west Africa are well acquainted with cross-births and seek to rectify them by external manipulations, but if these fail they will put the parturient woman on a cart and drive her over a rough road to shake the fœtus into better position. Other crude attempts to rectify the malposition are recorded in various tribes.

That internal manipulations for the rectification of cross-births and other malpositions have been practised in the past to some extent is certain. The ancient Hindu understood how to turn for cross-presentation and how to deliver breech presentations by pulling down the legs. Probably the Talmudists refer to the same thing. The writings of Soranus give plain directions with figures for dealing with various presentations by cephalic and podalic version and the Japanese in this direction also show skill and knowledge. There does not seem to be much evidence of the practice of internal manipulations amongst savage peoples of to-day. Engelmann emphasises the rarity of such a method of manipulating within the vagina. As exceptions we may notice that the Calmucks have for a long time been able to perform version in difficult labour. The modern Greeks are said by Ploss to seek the help of shepherds in difficult cases, for these have experience in the delivery of sheep. Emin Pasha found in Unyoro in Africa men who were able in arm presentation to replace the arm and to turn the child in the womb. Version is said also to be performed in Massana in East Africa and also by midwives in Algeria.

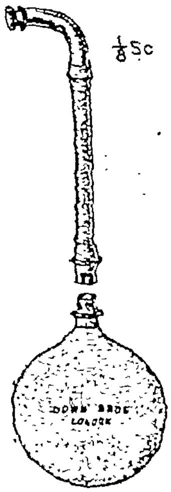
To pull violently on any presenting part is, on the other hand, the most obvious way of attempting delivery by those who do not understand anything about the anatomy of the parts. It is a sign of advanced knowledge to know when to refrain from doing it. Arms are often pulled off this way. I have been privately informed of a confinement in Africa where the head presented but would not advance, when a cord was tied round the neck of the child and then carried through a wall to be pulled by men outside the delivery chamber. The head, as might be expected, parted company with the trunk.

Embryotomy.—The idea that a child may be delivered in a difficult case by cutting it into pieces as far as it can be reached might occur to the savage mind and from this might come the discovery of the fact that perforating the head often is followed by speedy delivery after previous long delay. Susruta describes embryotomy and so do the ancient Greeks, who also employed hooks to assist in extracting the fœtus. Soranus describes the operation of embryotomy and speaks of its use in hydrocephalus, and from this time onwards it is well recognised. Amongst other nations we find mention of embryotomy performed with a knife by the medicine men of the Sungari (Manchuria). Schoolcraft describes a case amongst the Dacota Indians of an impacted arm presentation. The arm was cut off and the child extracted piecemeal by thoroughly ignorant women. Similar crude embryotomy is described by Baumstark as being performed amongst the Warangi in the Massai steppe in East Africa, and the necessity of delivery by destruction of the child is recognised amongst the natives of German South-west Africa. It is also performed in the same rough and dangerous fashion in extreme cases by women in Sumatra.

Cæsarean section.—Post-mortem Cæsarean section is of very ancient date and was even enjoined in the law of Numa Pompilius, and the Talmudist Rabbis discussed the legitimacy of the performance of post-mortem Cæsarean section on the Sabbath day. Niebuhr in the eighteenth century observed the practice amongst the Hindus; the child was buried if dead and the mother burned. In Malabar also, according to Speerschneider, the child was excised and buried separately. Emin Pasha relates that in Unyoro if the mother died in labour the child had to be removed with the knife, whether dead or alive. To neglect this was of evil presage for all concerned. From Bosnia comes an account of a horrible superstition which led thieves and burglars to kill a woman in the seventh month of pregnancy, extract the child, and cut it in pieces to make a charm which made the inmates of a house sleep like the dead while a burglary was being accomplished. A similar superstition is made the basis of one of the Ingoldsby *Legends* ("The Hand of Glory"). It is said by Ploss that even in 1889 this frightful superstition was in force. The removal of a living child from the living mother is said to have been first performed in 1500 by Nueffer. In a lecture published in THE LANCET of Jan. 9th, 1904, p. 76, I have given an account of this case. There are references to the operation in the Talmud and in the Norse Sagas and other legendary histories. But that which is of special interest in this place is the evidence that amongst savage nations in recent years Cæsarean section has been known to be successfully performed. The best example of this will be found in a paper by R. W. Felkin in the *Edinburgh Medical Journal* for April, 1884, a very accessible reference which everyone who may be interested in this subject should read. Felkin saw one case in which it was proposed to perform the operation, but obtaining permission to examine the patient he found it to be a simple case of uterine inertia, and he delivered with forceps. In a second case he was not allowed to examine and did actually see the operation performed by a man in Uganda, both mother and child surviving. The uterus was not sutured, the abdominal wound was closed with pins that are compared to acupressure needles, and with string made from bark which held the pins together. The woman made a rapid recovery. Schoolcraft speaks of a case amongst the Chippeway Indians in which a man successfully delivered his wife of a living child by Cæsarean section, but he did not witness the operation. And a slave woman in the West Indies is said to have delivered herself by abdominal section.

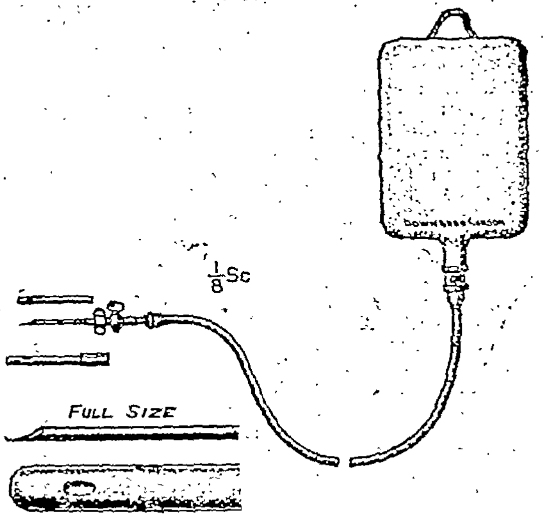
Support of perineum in labour.—In a certain number of instances it has been observed that native women give support to the perineum in labour. The practice is rare, but there are some well-established examples, as in certain tribes in defined, together with any infected glands or mesentery. The sigmoid flexure is rendered mobile by the careful separation from it and from the meso-sigmoid of the acquired adhesions already referred to. A sufficient length of bowel having been drawn out of the abdomen, it is divided with the cautery at such a point as to leave two or three inches of the proximal bowel protruding from the abdominal incision after the edges have been approximated by sutures. The mesentery of the distal bowel is separated from the sacrum as far down as possible and a ligature is tied firmly round the rectum at its lowest limit above the growth, any infected mesentery above the level of the ligature being thoroughly eradicated. The rectum is divided by the cautery immediately above the ligature. The ligatured stump is then inverted into the rectum and securely buried by purse-string and other sutures. Then the peritoneum of the pelvis lining its wall and the bladder in the male, and the uterus and broad ligament in the female, is picked up on a catgut suture so that that portion of the peritoneum of the pelvis which contains the rectal growth is completely separated by an artificial diaphragm from the general peritoneal cavity, and whatever disease still remains lies entirely below the protecting diaphragm which has thus been constructed. A curved tube fitted with a special rubber apparatus (Fig. 1), which I have employed for many years, is then tied into the portion of the sigmoid flexure left protruding from the abdominal incision, all fouling of the wound or discomfort to the patient during the whole period of convalescence being absolutely avoided by this means. The two or three inches of gut projecting from the wound is utilised to re-attach the glass tube as each section of bowel sloughs off with the constriction due to the ligature till the bowel is divided flush with the skin. This leaves a perfect aperture which is readily controlled by the rectus muscle and over which a cup and belt is worn without inconvenience.

FIG. 1.



After the operation the patient is put upon continual saline injections subcutaneously. Two pints are introduced into the axilla at once while the patient is still under the anæsthetic; during the three days following the operation about eight or ten pints are absorbed in this way by continued transfusion. To meet any risk of infection of the material introduced I devised an arrangement by means of which this can be effectually eliminated. It has also the advantage of occupying a very small bulk in the bag of the surgeon. It is made for me by Messrs. Down Bros. It consists of a bag made of the best rubber capable of containing two pints of water (see Fig. 2). It has a metal orifice sufficiently large to admit of the ordinary salt "tabloids." To this is joined a rubber tube by means of a bayonet catch, to which a suitable needle can be attached. This needle is fitted with a shield which serves the double purpose of keeping it covered after sterilisation and preventing any blunting of its point. A rectal nozzle is also supplied in the event of the surgeon wishing in certain cases to introduce the solution into the rectum. By using saline solution subcutaneously in this manner any sickness with the strain on the wound and the associated pain and distress is absolutely avoided, while the danger of shock to the patient from the operation is reduced to a minimum. I first employed this continual transfusion with the most marked success in cases in which I had removed the big bowel, with the result that the risks from the operation are very much reduced, while I believe the tendency to the formation of adhesions about the dilated small intestine, which is an occasional annoying sequence, is apparently obviated by it. The bag can be placed in any situation in or above the bed and its contents can be kept warm by placing it on a hot-water bottle, &c. If the solution does not run freely pressure can be exerted in it readily or it may be suspended at a greater height. To employ it the bag is filled with water after the salt has been introduced into it. The shield, tubing, and needle are then connected and the whole thing is put into any suitable vessel and boiled. The shield being taken off the needle, it is introduced between the cleansed skin and is fixed in position with a suitable dressing so as to assure asepsis at the seat of puncture.

FIG. 2.



After a fortnight has elapsed the remainder of the rectum is removed from below. This is done by a careful dissection of the rectum from the sacrum and from the bladder or vagina till the portion of the peritoneal cavity which has been shut off by the artificial diaphragm is encountered. From this peritoneal space into which the finger enters the remainder of the rectum is easily removed. The cavity left is drained in the usual manner and closes up rapidly.

One satisfactory result of this method of operating is that before the second step in the operation the patient gets about with comfort, and after the second step the sitting posture can be resumed after the lapse of a few days.

Cavendish-square, W.

THE METHODS OF PRIMITIVE MIDWIFERY.

BY JOHN BENJAMIN HELLIER, M.D. LOND.,
PROFESSOR OF OBSTETRICS IN THE UNIVERSITY OF LEEDS AND OBSTETRIC PHYSICIAN TO THE LEEDS GENERAL INFIRMARY.

I.

I WILL introduce my subject by quoting a description of present-day practice as observed by a member of our profession who was for many years in charge of a mission hospital in South India, who has kindly communicated it to me verbally. It gives an excellent illustration of the methods to which the reader's attention is invited.

When a Hindu woman is in labour all her relations crowd into the room. In an ordinary case they may let the woman go on as best she can, but in any case of difficulty they call in a so-called "barber woman." She is supposed to know something and claims to know a great deal, but as a matter of fact is completely ignorant and filthily dirty. Suppose the labour to be lingering or the case to be primiparous and that delivery does not follow as soon as expected, then skill. For those English and American ladies who having qualified themselves by a full curriculum at home have devoted their lives to helping *their suffering sisters* in regions remote from civilisation by skilful practice of scientific obstetric *art we feel a degree of respect and admiration which is beyond expression.*

Leeds.

OBSERVATIONS ON PHOSPHATURIA AND THE TREATMENT OF DISEASE BY CONVERSION.

BY REGINALD HARRISON, F.R.C.S. ENG.,
PAST VICE-PRESIDENT AND HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN interesting article on the conversion of diseases in a work by Dr. John Ferriar, physician to the Manchester Royal Infirmary, entitled "Medical Histories and Reflections," published in 1795, opens with the following passage: "A disease is said to be converted when new symptoms arise in its progress which require a different designation and which either put a period to the original disorder or combining with it alter the physician's views respecting the prognostics or the method of cure." In the course of this article, which is now as suggestive as it was when written over 100 years ago, numerous illustrations from practice in support of his views will be found. I am mainly interested in one of Dr. Ferriar's references which provides an additional reason for ventilating the application of conversion in the instance I am taking. The reference is as follows: "It must be added that general fever sometimes cures local inflammation; Mr. Hunter says he has seen a gonorrhœa extinguished by the accession of a fever." Such an experience must not be unknown to many others.

It has not infrequently been observed in the treatment of chronic urethritis and muco-purulent discharges following it, irrespectively of the internal administration of alkalies and often imperceptibly to the patient himself, that the urine became altered in character and assimilated with that known as phosphaturia. And, further, that when this change was observed the cessation of the discharge or gleet, as it is commonly called, for which the patient had originally come under treatment, usually soon followed, either spontaneously or by treatment appropriate to the phosphaturic state without apparent reference to the cause which preceded it. This casual observation raised the question whether it was possible that there was any relationship between this incident and what followed, whether, in fact, the phosphaturic state of the excretion was inimical to the existence of the infecting bacillus. The observation was made so frequently as to suggest this and led to the systematic examination of the urine and other discharges for gonococci in all persons coming under treatment for gleet more carefully and frequently than previously. From them the following conclusions appeared to be grounded.

1. That in a considerable number of instances thus designated and of undoubted specific origin there was no evidence at the time of my examination that there was anything wrong with the urine or with any urethral discharge complained of inconsistent with the phosphaturic *state alone.* This condition was either apparent to the eye on allowing the urine to stand for a short time in a *glass vessel* or was evidenced by boiling the excretion *when any cloudiness* which followed was *immediately removed by the addition* of nitric acid. Here any pus corpuscles which the microscope detected were physically *explainable by the crystalline* precipitates the urine contained and which were often present in sufficient quantities *to give this excretion* a semi-purulent or opaque appearance. How or when this phosphaturic transformation *took place in the history* of an ordinary case of chronic infecting urethritis was not always easy to determine. *In many instances* which were carefully tested and microscopically examined this change appeared to mark the concluding stage of gonococcal life and was also often coincident or nearly so with the adoption of such treatment as the phosphaturic state usually requires. Further, these examinations showed how easily and frequently phosphaturia may counterfeit and be treated for a specific urethritis and even be intensified by the remedies commonly used for the latter.

2. The second inference was that the artificial production and temporary continuance of a state of phosphaturia might be utilised in the treatment of specific gleety affections following upon gonococcal infections. To produce a urine having the prominent features of phosphaturia by the administration of alkalies—bicarbonate of potassium was generally selected for this purpose—is not a matter of much difficulty or of any detriment to the patient. The effect on the urine should be sufficient to render it responsive to the usual tests, microscopical and otherwise, by which phosphaturia is recognised, and not merely to produce an alkaline reaction to test paper. Further, it is necessary to maintain this condition for some little time, during which period all local applications should be suspended. It will usually be found after a period of ten days or so and as the phosphaturic condition gradually passes off under the influence of altered treatment and diet appropriate to this state that no signs will be found such as were previously complained of. In some instances the artificially induced phosphaturia was slow in passing off, whilst in others its presence appeared to have been too limited to effect the desired object and required repetition. On the whole, however, the results have proved satisfactory. There was a time when infecting urethritis—at all events in its earlier stages—was very generally treated by the administration of alkalies, though the reason for this was not such as I am offering. I am not at all sure in the matter of rapidity of cure that we have much improved upon this older practice by the more mechanical processes which are now often substituted.

If these observations are found in their wider application such as I have construed them a more convenient and less unpleasant method of treatment may be arrived at. They have extended over some years, and though they may not embrace the whole truth they may be read in the light of a contribution towards it.

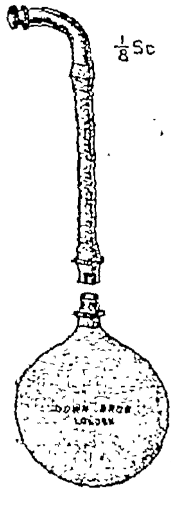
Lower Berkeley-street, W.

HÆMO-PERICARDIUM ASSOCIATED WITH SYPHILIS.

BY J. LOUGHEED BASKIN, L.R.C.P., L.R.C.S. EDIN.,
MEDICAL SUPERINTENDENT, FISHERTON ASYLUM; LATE DEPUTY MEDICAL SUPERINTENDENT, DEVON COUNTY ASYLUM.

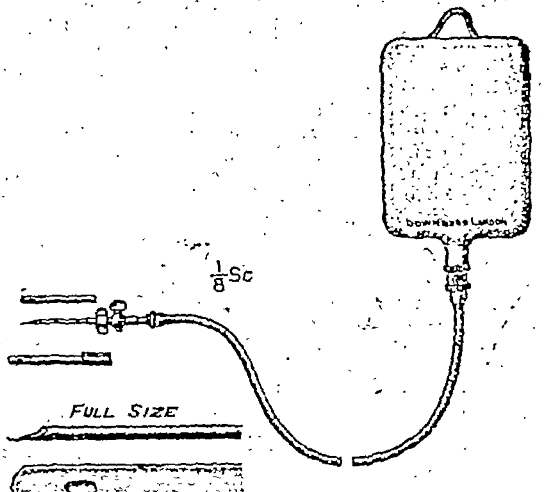
THE following case came under my *notice some time ago* and presents some interesting *features. The patient was* a married man, aged 65 years, of German nationality. When first examined *by me he was fairly well nourished* and well developed. His expression was gloomy and unintelligent; he was partly *demented*; *he retained* a delusion that he had been given 129 pints of medicine in one dose at a hospital. No *other symptom* of megalomania had been forthcoming and his general condition alternated chiefly between emotional *restlessness* and apathy. The *skin* of his entire body was very dry and slightly jaundiced. On the skin over the *sternum* and the interscapular region were several scars of either circular or crescentic shape, each of the size of a large pea. There was a painless swelling on the anterior border of the right tibia of the size of a florin and below this and immediately above the ankle were several small cicatrices irregular in shape; on the left leg were several ulcers with "punched-out edges" below the tuberosity of the tibia, and several similar ulcers on each forearm and extending on to the dorsum of the hand, and vaccination marks on the left upper arm. He walked slowly and with some stiffness of the hip-joints; the patellar reflexes were diminished and delayed; his grasp was feeble. Babinski's sign was absent and ankle clonus was not elicited. His right pupil was larger than the left; both reacted sluggishly to light and for the process of accommodation; the consensual reflex was present. The hearing was bad on each side; his tongue protruded in the middle line and was fleshy and grossly tremulous and *furred* posteriorly. He had only four teeth in his mouth (in the upper alveolus) and those were *carious.* His palate was unduly arched anteriorly. The cardiac sounds were irregular in rhythm; a slight bruit was audible at the first sound; his pulse was 70 and the radial and temporal arteries were tortuous and thickened. The respiratory system was healthy. His appetite was good; his intestinal movements were performed regularly. The liver was tender but no enlargement or alteration in shape or surface was discoverable. There was a brown discolouration on the glans penis one-eighth *of an inch in* defined, together with any infected glands or mesentery. The sigmoid flexure is rendered mobile by the careful separation from it and from the meso-sigmoid of the acquired adhesions already referred to. A sufficient length of bowel having been drawn out of the abdomen, it is divided with the cautery at such a point as to leave two or three inches of the proximal bowel protruding from the abdominal incision after the edges have been approximated by sutures. The mesentery of the distal bowel is separated from the sacrum as far down as possible and a ligature is tied firmly round the rectum at its lowest limit above the growth, any infected mesentery above the level of the ligature being thoroughly eradicated. The rectum is divided by the cautery immediately above the ligature. The ligatured stump is then inverted into the rectum and securely buried by purse-string and other sutures. Then the peritoneum of the pelvis lining its wall and the bladder in the male, and the uterus and broad ligament in the female, is picked up on a catgut suture so that that portion of the peritoneum of the pelvis which contains the rectal growth is completely separated by an *artificial diaphragm* from the general peritoneal cavity, and whatever disease still remains lies entirely below the protecting diaphragm which has thus been constructed. A curved tube fitted with a special rubber apparatus (Fig. 1), which I have employed for many years, is then tied into the portion of the sigmoid flexure left protruding from the abdominal incision, all fouling of the wound or discomfort to the patient during the whole period of convalescence being absolutely avoided by this means. The two or three inches of gut projecting from the wound is utilised to re-attach the glass tube as each section of bowel sloughs off with the constriction due to the ligature till the bowel is divided flush with the skin. This leaves a perfect aperture which is readily controlled by the rectus muscle and over which a cup and belt is worn without inconvenience.

FIG. 1.



After the operation the patient is put upon continual saline injections subcutaneously. Two pints are introduced into the axilla at once while the patient is still under the anæsthetic; during the three days following the operation about eight *or* ten pints are absorbed in this way by continued transfusion. To meet any risk of infection of the material introduced I devised an arrangement by means of which this can be *effectually* eliminated. It has also the advantage of occupying a very small bulk in the bag of the surgeon. It is made for me by Messrs. Down Bros. It consists of a bag made *of* the best rubber capable of containing two pints of water (see Fig. 2). It has a metal orifice sufficiently large to admit of the ordinary salt "tabloids." To this is joined a rubber tube by means of a bayonet catch, to which a suitable needle can be attached. This needle is fitted with a shield which serves the double purpose of keeping it covered after sterilisation and preventing any blunting of its point. A rectal nozzle is also supplied in the event of the surgeon wishing in certain cases to introduce the solution into the rectum. By using saline solution subcutaneously in this manner any sickness with the strain on the wound and the associated pain and distress is absolutely avoided, while the danger *of* shock to the patient from the operation is reduced to a minimum. I first employed this continual transfusion with the most marked success in cases in which I had removed the big bowel, with the result that the risks from the operation are very much reduced, while I believe the tendency to the formation of adhesions about the dilated small intestine, which is an occasional annoying sequence, is apparently obviated by it. The bag can be placed in any situation in or above the bed and its contents can be kept warm by *placing it on a hot*-water bottle, &c. If the solution does not run freely pressure can be exerted in it readily or it may be suspended at a greater height. To employ it the bag is filled with water after the salt has been introduced into it. The shield, tubing, and needle are *then connected* and the whole thing is put into any suitable vessel and boiled. The shield being taken off the needle, it is introduced between the cleansed skin and is fixed in position with a suitable dressing so as to assure asepsis at the seat of puncture.

FIG. 2.



After a fortnight has elapsed the remainder of the rectum is removed from below. This is done by a careful dissection of the rectum from the sacrum and *from* the bladder or vagina till the portion of the peritoneal cavity which has been shut off by the artificial diaphragm is encountered. From this peritoneal space into which the finger enters the remainder of the rectum is easily removed. The cavity left is drained in the usual manner and closes up rapidly.

One satisfactory result of this method of operating is that before the second step in the operation the patient gets about with comfort, and after the second step the sitting posture can be resumed after the lapse of a few days.

Cavendish-square, W.

THE METHODS OF PRIMITIVE MIDWIFERY.

BY JOHN BENJAMIN HELLIER, M.D. LOND.,
PROFESSOR OF OBSTETRICS IN THE UNIVERSITY OF LEEDS AND OBSTETRIC PHYSICIAN TO THE LEEDS GENERAL INFIRMARY.

I.

I WILL introduce my subject by quoting a description of present-day practice as *observed* by a member of our pro*fession who was* for many years in charge of a mission hospital in South India, who has kindly communicated it to me verbally. *It gives an excellent* illustration of the methods to which the reader's attention is invited.

When a Hindu woman is in labour all her relations crowd into the room. In an *ordinary* case they may let the woman go on as best she can, but in any case of difficulty they call in a so-called "barber woman." She is supposed to know something and claims to know a great deal, but as a matter of fact is completely ignorant and filthily dirty. Suppose the labour to be lingering or the case to be primiparous and that delivery does not follow as soon as expected, then

A CASE OF ENUCLEATION, DURING THE SEVENTH MONTH OF PREGNANCY, OF A UTERINE FIBRO-MYOMA WEIGHING 17½ POUNDS; PREMATURE LABOUR TWO DAYS LATER.[1]

BY HERBERT WILLIAMSON, M.A., M.B. CANTAB., M.R.C.P. LOND.,

ASSISTANT PHYSICIAN ACCOUCHEUR TO ST. BARTHOLOMEW'S HOSPITAL; PHYSICIAN TO OUT-PATIENTS, QUEEN CHARLOTTE'S LYING-IN HOSPITAL.

ON Dec. 15th, 1906, I was asked by Dr. T. H. Fowler of Epping to see a woman in whom pregnancy was complicated by the presence of an abdominal tumour. The patient was 32 years of age and had been married for 15 months. Menstruation commenced at 14 years of age. The periods had always been regular every 28 days, had lasted six days, and the amount lost had never been excessive. The date of the last period was June 15th to 21st, 1906. Shortly after this the patient became pregnant and from that time no vaginal hæmorrhage occurred. Previous to conception she was in her usual health, had not noticed any enlargement of the abdomen, and had not found it necessary to loosen her clothes. Towards the end of September, 1906, in the fourth month of her pregnancy, whilst engaged in her household duties, she was seized with acute abdominal pain. The pain did not cause vomiting but was so severe that she was unable to stand upright. She went to bed and remained there for two days, the pain gradually subsiding. A few days later in the early part of October the pain was so much less that she undertook a short railway journey and whilst in the train was seized with another attack similar to the last, though more severe. She was unable to sit or lie down but had to finish the journey standing up clinging to the carriage door. On reaching her destination she was put to bed and remained there for six days but gradually recovered and at the end of another week was able to return home. To use her own words, "the journey home seemed to bring back the pain." For a fortnight she was confined to her bed and from that time until I saw her some five weeks later was unable to leave her room. There was rapid loss of flesh and the abdomen became distended to such a degree that it was impossible for her to lie down. Fœtal movements were felt in November and from that time onwards. On Dec. 15th I made the following note: "The patient looks ill and is anæmic; she is very thin, almost emaciated. The tongue is furred. Temperature 99·5°. Pulse 100, of poor volume. When lying down there is grave difficulty in respiration. The breasts are active and contain secretion. The abdomen is enormously distended, the skin over it tense and shining, a number of large dilated veins are seen on the surface. On palpation the abdomen is tender all over. Two tumours can be detected. The larger lies to the right; it is hard, feels solid, and nodular on the surface; it extends upwards for a considerable distance beneath the costal margin and has displaced the diaphragm causing respiratory embarrassment. It reaches well beyond the middle line and descends into the pelvis. The second tumour lies to the left and below; its limits cannot be accurately determined, for it is overlapped by the one just described; it lies over the left iliac fossa and bulges the abdominal wall outwards in the left flank. Its consistence is soft and elastic, like that of the pregnant uterus; fœtal parts cannot be distinguished nor can the fœtal heart be heard. The uterine souffle is clearly audible. Per vaginam the cervix is soft and lies high up to the left; the finger can be introduced through the os internum, the bag of membranes can be felt, and in this a child's foot which moved on touch. Bimanually, the tumour to the right rests upon the pelvic brim, whilst the lower pole projects into and occupies the right half of the pelvic cavity. The tumour to the left is identified as the pregnant uterus."

As to the nature of the mass to the right I was in grave doubt but thought it was probably a rapidly growing malignant tumour of the ovary. The reasons which led me to form this opinion were briefly these: (1) the rapidity of growth was in favour of a tumour of the ovary rather than of the uterus, yet the tumour felt too hard and inelastic for an ovarian cyst; (2) I could not satisfy myself that the tumour was definitely connected with the uterus; and (3) the cachectic appearance of the patient, the rapid loss of flesh, and the evidences of a toxæmia were in favour of a malignant growth. In spite of this view I urged strongly that an exploratory operation should be undertaken because it was clear that the patient would soon die from respiratory trouble if nothing were done and also that delivery of the child *per vias naturales* was an impossibility. The patient and her friends consented to my proposals and she was brought up to town on an ambulance.

On Dec. 19th I opened the abdomen by an incision in the middle line. The incision was subsequently enlarged so that it extended from two inches above the pubes nearly to the ensiform cartilage. When the abdomen was opened two tumours presented; the pregnant uterus deep red in colour lying below and to the left and a large nodular growth lying to the right extending upwards beneath the costal margin and downwards into the brim of the pelvis. The tumour was adherent to the parietal peritoneum, to the bowel and omentum, but the adhesions were easily separated. I found that the growth was a fibro-myoma attached to the right side of the anterior aspect of the uterus by a pedicle rather thicker than a man's wrist. After separating the adherent viscera it was brought out of the abdomen without difficulty and enucleated from the uterine wall. I do not think I opened the uterine cavity during this procedure but the mucosa was exposed. Free hæmorrhage occurred from the cavity left in the wall of the uterus after enucleation. So free was the bleeding that I feared it would be necessary to complete the operation by performing Cæsarean section and possibly hysterectomy. Eventually, however, by underpinning the whole of the raw surface and closing it in by means of cat-gut sutures the hæmorrhage was arrested. The abdominal wound was closed by through-and-through sutures with a separate layer for the fascia. For 48 hours the progress was entirely satisfactory, but on the morning of Dec. 21st labour pains commenced and after a short and easy labour the patient was delivered of a six months child which lived only 18 hours. There was no post-partum hæmorrhage but with the expression of the placenta two masses of dark blood-clot, each of the size of a hen's egg, were expelled. These clots were evidently two or three days old, and I have very little doubt that during the manipulation of the uterus I partially detached the placenta. To this accident is to be attributed the onset of labour. From this point convalescence was uninterrupted and the patient returned home a month after the operation. I noticed a number of fibroids in the wall of the uterus, one of the size of a Tangerine orange and two or three others nearly as large as this. When the patient came to see me six months later the uterus had involuted well and the whole mass, uterus and fibroids, was no larger than a man's fist. There can be no doubt that in this case the individual fibroids were much smaller six months after delivery than at the time of labour.

I show to-night a portion of the tumour removed. Its weight was 17½ pounds, its length 12½ inches, its breadth 9 inches, and its circumference 25 inches. On section it is seen that the tumour is degenerate, more especially towards its centre. Areas of mucinoid degeneration, cyst-like cavities, and patches of necrobiotic tissue are scattered through it. Microscopical sections show the histological appearances commonly seen in a degenerating fibro-myoma. These call for no special description.

I have related this case because of its clinical interest and because it is important to record instances in which premature expulsion of the ovum follows operations upon the uterus during pregnancy. So many cases have been published of pregnancy continuing in spite of the enucleation of uterine fibroids that a false idea of the safety of the ovum may become prevalent unless our failures are recorded also. I do not mean to imply that abortion is the rule, but it occurs with sufficient frequency to make me hold that a fibroid should not be enucleated during pregnancy unless it causes, or clearly threatens to cause, urgent symptoms.

The rate of growth in this case is remarkable. I have no doubt that the tumour existed before the commencement of pregnancy, but it had been noticed neither by the patient nor her friends. Its increase in size must be attributed to two factors: (1) the richer blood-supply of the uterus associated with gestation; and (2) the degenerative changes in the tumour partly mucinoid and partly necrobiotic. It is tribes that a childbirth may be only an incident in a day's march, the woman after an hour or two resuming her walk carrying her newly born child, or mounting her horse and galloping on after her company, and many native races know almost nothing at all of a "lying-in" period. But on the other hand, as soon as the more natural conditions are interfered with difficulties and dangers arise. Even amongst the former class such conditions as the falling of the womb and of the vaginal walls have a notable frequency. Intermarriage of different races, especially of lower with higher, produces dystocia, and women with half-breed children often die in labour. But the evidence available suffices to make it abundantly clear that amongst untaught nations there is a very serious amount of ignorance, maltreatment, and brutality which entail a vast amount of suffering and death which might be avoided by the introduction of Western methods. Let no one adopt the comfortable notion that it is superfluous to seek to diffuse scientific obstetric teaching in the world. One object of this paper is to prove the contrary.

---

[1] A paper read at a meeting of the Obstetrical and Gynæcological Section of the Royal Society of Medicine on Jan. 9th, 1908.

Let us take an example. China is known to be a land well advanced in certain arts. How is it with midwifery? In the *China Medical Missionary Journal* for 1890 Dr. J. C. Thomson tells us that Chinese women naturally suffer less and have easier deliveries than Western women, but owing to the violent massage and other manipulations to which they are subjected the severest ruptures and lacerations are seen, with all the inevitable consequences of sloughing, necrosis, sepsis, and death. The mortality in childbed is excessively high, and he says: "In the practice of obstetrics in China we see century after century of the blindest empiricism, with no ray of medical science to shine into the habitations of cruelty."

As examples of the atmosphere of ignorance and superstition in which such races dwell I may remind the reader that many races recognise no death from natural causes, ascribing all fatalities to witchcraft or "the evil eye," or to the malevolence of some supernatural being. We find such absurdities as the custom of putting the husband to bed when the child is born, whilst the wife waits upon him.[1] Amongst one tribe of Finns the pregnant woman changes her shoes every month to throw off her tracks the devil who is waiting to devour the newly born child. The Chinese hold that pregnancy may last for three years if the child does not wish to leave the womb. The Indian women will whisper to the unborn child that a rattlesnake is near so as to induce the child to leave the womb. Chinese women will wear stockings which have been blessed by the lama, so as to expedite delivery, and will swallow pilules of paper on which magic words are written, while for cross-births a remedy is found in the ashes of the husband's hair. Examples of such puerile and ludicrous practices could be multiplied indefinitely.

III.

We will now consider some of the actual methods employed in primitive midwifery with some allusion to traces of the same amongst more civilised peoples. The different *postures* occupied by women in labour have been studied by Engelmann and Ploss and will be found described and illustrated in the works already referred to. The most common and natural position in ordinary cases seems to be a squatting posture, like that of defæcation, but almost every conceivable position has been noted.

Administration of internal remedies.—Of world-wide prevalence is the use of medicines to strengthen the patient, to ease her sufferings, or to excite uterine action. Probably every kind of aromatic drug has been employed for this purpose. The Hippocratic school esteemed silphion which the Latin calls laserpitium and which was perhaps asafœtida. The Romans used pomegranate and fenugreek, and the Arab physicians use an enormous number of drugs, and amongst European nations honey, myrrh, henbane, adderswort, castor, savin, mint, rue, pepper, cinnamon, figs, various balsams and oils, and so on, infused in water, wine, or beer. Amongst other nations than European we may select from many examples, turnip juice (Caribs), decoction of tobacco in cow or ewe milk (Hottentots), decoction of opium (Chinese), the powdered vertebræ of the electric eel (Venezuelans), slippery elm (North American Indians), and so *ad infinitum*. Nauseous and repulsive substances also may be employed such as cold water in which a woman has just washed her feet or even urine (a tribe in the Dutch East Indies), and sometimes irritant or poisonous substances. Emetics have been widely used. Engelmann depicts a midwife amongst the Kiowa Indians blowing an emetic into the mouth of a parturient woman. It is obvious that the straining caused might act on the uterus mechanically. The Chinese often excite vomiting and uterine action by thrusting the woman's own pigtail down her throat till she is sick. Sternutatories played a considerable part in ancient midwifery. They were condemned by Soranus but are advocated by Roesslin. Ergot does not seem to have been used until the sixteenth century. To deprive a woman of food or drink or both from the beginning to the end of labour is a not uncommon custom. This was the practice in Germany in the seventeenth century: while the woman was on the "birth-chair" absolutely nothing to take was allowed her. In some parts of India it is thought to be very dangerous for a woman in labour to drink water.

External remedies.—The use of unguents to facilitate delivery is one of the oldest practices in obstetrics. Susruta, whose date is anything up to 1000 B.C., recommends anointing of the external and internal genitals. Similar advice is given by Moschion, Aëtius, Paulus Aegineta, and Avicenna, and the practice has continued to the present day, and it is only modern aseptic ideas that exclude these miscellaneous lubricants. The abdomen also is rubbed with various medicaments. For example, I may mention the use of oil in Guatemala, of an infusion of an astringent plant in Mexico, of Kalapa milk in the Babber Islands, and of a mixture of fat and brandy in Galicia. The Greeks and Romans used medicated bougies or pessaries placed in the vagina or os uteri.

Baths and affusions.—These are also employed. For example, hot water is applied to the abdomen in Peru. Some Australian tribes pour cold water over the abdomen. In Doreh, in New Guinea, the parturient is held by two other women while a third pours cold water over her till the child is born.

Vapour baths and fumigations have a very wide distribution. Felkin gives a sketch from a tribe on the White Nile of a woman who is in labour and is squatting over a hole dug in the ground in which is a fire and over it a pot containing a decoction of herbs. The rising steam is said to make labour easier. Steam baths with medicated vapour are similarly used in Russia, in China, and in many other places. In Central California in difficult labour a plaster consisting of hot ashes and wet earth is placed on the abdomen. The Arabians used many such methods and in the oldest German works for midwives many substances are recommended for fumigation, such as galbanum, castor, cow's hair, sulphur, opopanax, and the dung of pigeons or hawks. In German South-West Africa in lingering labour the woman is placed in a bath or has applied to her body the abdominal viscera of a recently killed ox, while the still moist skin serves for a wrap. These are sufficient examples of very widespread practices.

Mechanical assistance to women in labour by employment of external force.—The idea that labour may be assisted by pressing or squeezing the abdomen is obvious, and very primitive, and has given rise to almost universal practice. It has a basis of sound principle in it, and applied within due limits and according to right methods it has a well-recognised place in obstetric art, but nothing that we shall discuss in this paper shows more forcibly how a right idea may be exaggerated and abused till it gives rise to the most brutal and dangerous malpraxis. Gentle finger pressure and massage, rhythmic and well designed, may really be of service in exciting pains and even in rectifying cross-births; and massage has been very widely practised in various times and amongst various races. The Japanese may be especially mentioned for their skill in this respect. As varieties and examples of the more violent methods of applying external force I may mention: 1. Violently kneading the abdomen of the parturient or giving blows with fists, knees, or feet, or by butting with the head. 2. Forcible compression with the arms. For this purpose the helping woman may sit behind the patient and compress the womb with hands clasped around the abdomen. Sometimes the husband or a strong man may be employed for this purpose. The woman may kneel or stand meanwhile or may even be hanging to a bar or partially suspended to a tree-trunk or branch. 3. The pressure may be made with a bandage surrounding the abdomen, the ends being pulled by one or more women or by a man. 4. Or pressure may be made by kneeling or standing on the patient's abdomen while she lies on her constipation relieved by enemata was due to sluggish action of the lower part of the colon. But enemata were not often employed without the simultaneous administration of purgatives, so that it had not been possible to separate clinical groups of cases in which enemata and not aperients were indicated. He had attempted by the aid of the x rays to discover what part of the intestines was to blame in different cases of constipation and thus to obtain a rational basis for treatment. It was only in the severer forms of chronic constipation such as those in which the question of operative interference might arise that the somewhat prolonged investigations required could be profitably carried out in practice. But he hoped that the examination of a large number of cases of constipation of every variety and degree might lead to the discovery of some simple clinical signs which would show what part of the intestines was at fault. It might also be possible to discover by similar means the exact effect of the various drugs and other measures employed in the treatment of constipation so that each case might be provided with a suitable treatment. The method employed consisted in the administration at breakfast of one and a half ounces to two ounces of bismuth carbonate mixed with bread-and-milk and then subsequently periodically examining the patients with the aid of the x rays. This large dose of bismuth had never produced any unpleasant symptom and on no single occasion in healthy individuals was constipation or any other disturbance of the normal activity of the alimentary canal produced. The time relations obtained by means of the x rays could therefore be looked upon as normal. The average normal time for the food to reach the cæcum was four and a half hours. Two hours more were required for it to reach the hepatic flexure and another two and a half hours for it to reach the splenic flexure. The rate of passage through the descending colon was somewhat slower and the activity of all parts was lessened during sleep. In a severe case of constipation described by Dr. Hertz the method showed that the passage of the intestinal contents through the colon as well as through the small intestine was unduly rapid rather than unduly slow. By means of the investigation with bismuth he found that the seat of the constipation in this case was the sigmoid flexure and the rectum. The rectum was considerably distended and fæces were present in the anal canal but the patient experienced no definite desire to defæcate. That meant that the rectum and anal canal must have become so far anæsthetic that the normal defæcative reflex no longer occurred. That together with the atonic condition of the sigmoid flexure and rectum caused the constipation. In this case by the use of daily enemata the constipation was "done away with" and the toxic symptoms and the pain were relieved. After this treatment an investigation made with bismuth carbonate showed that the sigmoid was no longer distended and that the bismuth passed at the normal rate through the intestines. Dr. Hertz then proceeded to relate the circumstances of a second case of severe constipation of 33 years' duration in a woman, aged 44 years. In this case as in the former one, bismuth carbonate passed through the small intestine at the normal rate and the distance reached in the first 28 hours also was not abnormal, but from the last part of the transverse colon onwards there was considerable delay. The constipation was probably due to anæsthesia of the rectum and anal canal and atony of the muscular wall of the pelvic colon and rectum. Dr. Hertz did not consider that the case would have been suitable for the operation of colectomy. In this case by the use of daily enemata the pelvic colon and rectum were prevented from becoming distended. The abdominal pain due to the fæcal mass disappeared with the enema treatment and the patient felt in every way better. It this case it was found that the patient did much better when the enema was given at night just before going to bed. In a case of tabes dorsalis and one of lead poisoning Dr. Hertz described the effect of drug treatment and observed in regard to a case of constipation in chlorosis that the cause was due to the sluggish action of the part of the large bowel beyond the middle of the transverse colon and if the case proved to be typical of the constipation of chlorosis it explained why ordinary aperients were able to relieve the constipation as the sluggish action occurred in a part of the intestines which was readily influenced by drugs. In the case of a patient suffering from constipation with neurasthenia the bismuth carbonate method showed that the constipation was due to sluggish action of the colon beyond the hepatic flexure, the last part of the transverse colon being most at fault. By treatment with liquor strychninæ and magnesium sulphate the condition was relieved and the bowels became regular.—Dr. H. Morley Fletcher asked what was the position of the patient when the x ray photograph was taken.—Dr. C. E Beevor said Dr. Hertz had given interesting details concerning constipation in cases where there were definite causes for the condition. What was the explanation of constipation coming on in a man between 50 and 60 years of age who found himself compelled to use purgatives or enemata?—Dr. F. de Havilland Hall laid stress on the importance of giving enemata at night time.—Dr. Hertz, in replying, said that the position of the patient when x ray photographed was lying down, but there was now at Guy's Hospital an apparatus by means of which the x ray investigation could be carried out with the patient in the upright posture. In regard to the question asked by Dr. Beevor, Dr. Hertz said that he had not examined such a patient, but he considered the constipation was similar to that seen in cases of the neurasthenic type.

---

[1] See Lubbock: Origin of Civilisation and Primitive History of Man, chap. I.

DERMATOLOGICAL SECTION.

Exhibition of Cases.

A meeting of this section was held on Jan. 16th, Dr. H. Radcliffe Crocker, the President, being in the chair.

Dr. E. G. Graham Little showed a young girl with Granulomatous Swellings on the hand, wrists, ankle, and neck, which seemed to be of the same type as the cases of disease grouped under the title of "granuloma annulare." A specimen of a section of the skin was shown and its appearance was like that described in some cases of the disease to which this name had been applied. Several members suggested that the skin lesions were like those of acnitis, and it was decided to try the effect of a Calmette ophthalmo-tuberculin reaction.

Dr. J. M. H. MacLeod showed a case of Annular Lichen Planus in a man in whom the lesions were confined to the penis and the forearm. The annular lesions could be traced as being formed by the peripheral extension and central involution of papules.

Dr. J. A. Ormerod showed a case of very extensively distributed Pityriasis Rubra Pilaris in a man, aged 30 years. In spite of the wide area of surface covered the scalp was little affected.

The President and Mr. George Pernet showed a Case for Diagnosis—a man with a number of Circumscribed Patches of Redness and Scaliness, the skin being free both from infiltration and atrophy. This case had been seen by a dermatologist in Chicago and had been published as an example of parakeratosis variegata. Diagnoses of mycosis fungoides and of leprosy had also been offered. The exhibitors thought the case corresponded more nearly with the type of xantho-erythrodermia perstans.

The President and Mr. Pernet also showed a case of Lichen Planus Verrucosus treated with the violet rays of a mercurial vapour vacuum tube. The patient had benefited greatly by this treatment.

Dr. J. H Sequeira showed a case of Tuberculides in a girl, aged 19 years, in whom the lesions had been noted for several years. These were of the type of acnitis. The opsonic index had been found to be 1·1. Calmette's ophthalmo-tuberculin reaction had been demonstrated in this case, but there was no other evidence of tuberculosis in the patient and there was no family history of the disease.

Dr. J. H Stowers showed a case of a small Rodent Ulcer on the Bald Scalp of a man, aged 53 years. This was of the size of a threepenny-piece and had lasted for 12 months.

OPHTHALMOLOGICAL SOCIETY.

Microphthalmia resembling Glioma.—Optic Neuritis in Cerebral Tumours.—Carcinoma of Orbit.—Coloboma of Iris in Each Eye.—Exhibition of Specimens.

A meeting of this society was held on Jan. 30th, Mr. R. Marcus Gunn, the President, being in the chair.

Mr. M. S. Mayou described a case of Microphthalmia resembling Glioma, with lenticonus and hypertrophy of the ciliary body. He said that the case belonged to the class of phthisis bulbi. Some of those cases had been of inflammatory origin, but this, and possibly some of the other cases, were attributable to the imperfect development of the mesoblast

Palestine, Russia, and India, and also in Japan and Persia. In the East Indies rags are sometimes stuffed into the anus and in Southern India a bag of ashes has been used to support the perineum. In our survey of primitive midwifery it is possible to find many grains of common sense amongst an overwhelming quantity of rubbish.

IV.

Treatment of the umbilical cord.—The widest differences are observed in this respect. The severance may be made by the father or by an assisting woman, or by the mother herself. It may be bitten through with the teeth, the mother even doing this for her own infant. It may be cut with sharp shells or sharp stones or pieces of wood, or with a kind of knife or saw fashioned from bamboo, &c. Sometimes the cord is ligatured with vegetable fibre or string, or may be tied in a knot. Many tribes never ligature. The cord is then often divided with a blunt instrument and being torn and crushed natural hæmostasis may be thus secured. Often some rough kind of styptic is applied to the fœtal end, such as ashes or charcoal or chalk. Sometimes it is cauterised with a glowing piece of wood or iron. In some parts of China the end of the cord is wrapped in oiled paper and then ignited. Fatal hæmorrhage is common when these primitive methods are in vogue. The cord may be cut close to the body, or, on the other hand, be left very long, sometimes even looped around the neck of the child. Umbilical hernia is a common result of such modes of treatment. The cord may be divided as soon as the child is born, or not till the placenta is delivered, and the placenta may undergo various anointings and washings first. Sometimes the child's body is twisted round directly after birth, so as to produce torsion of the cord.

Delivery of the placenta.—In very many cases where labour is easy the woman is delivered without assistance and remains squatting on the ground and straining till the placenta comes, as with patience it usually will. Sometimes, although the placenta is retained, no further efforts are made to extract it and this, of course, may lead to septic symptoms. To assist the delivery of a retained placenta all kinds of drinks are in use, also emetics, disgusting nauseants, and sternutatories. Sometimes the finger is thrust into the patient's mouth till she vomits or a lock of her hair is used for the same purpose; in China I am told by my friend Dr. O. Wenyon that the woman's own pigtail is thus employed. Barbarous methods are also common. The woman may be made to stand up and jump or be jolted by others. Amongst the Khirgis we read of her taking a wild ride on horseback over hill and dale to dislodge the retained placenta, often returning more dead than alive. The steam or vapour bath is used for this purpose also. To pull on the cord when the placenta is not delivered as soon as is deemed proper is a universal error. Fatal hæmorrhage, inversion, and prolapse follow this practice. Some tribes tie a stone to the cord and let the woman walk about. Others tie the cord to the thigh to prevent the imaginary danger of the placenta being drawn up into the abdomen. There are some tribes amongst the North American Indians who have learned that only gentle traction is permissible; it is obvious that when the placenta is lying in the vagina traction on the cord will appear to be a brilliantly successful method. Abdominal manipulations for the same end are common all the world over. They vary from gentle massage with perhaps inunction of oil to firm or severe hand compression of the uterus, violent kneading of the abdomen with fists, or pressure with hot stones placed on the abdomen. Worse still, a woman may stand on the patient's abdomen kneading violently with her feet; or, while the patient stands erect she may be clasped forcibly around the body. The abdomen may be compressed by a cloth passed around it and dragged or twisted with a stick after the manner of a tourniquet. Also water may be poured from a height on to the abdomen. That very serious injuries often result from the more violent measures it is unnecessary to say. Internal manipulations for placental extraction are not very common, but examples are recorded in various parts. Some of the North American Indian women have been known to introduce the hand, and so in India and some of the Pacific Islands. In German South-West Africa Lübbert has seen this done with very great care and very reasonable precautions. Here, also, the Japanese are distinguished by careful treatment of the third stage of labour.

Treatment of post-partum hæmorrhage.—All sorts of drugs and decoctions are in use. Kneading of the abdomen is a more rational remedy and doubtless is often effective. It is often done with great violence and we read of a woman being made to stand against a wall while another woman strikes the abdomen with her head or her knee (Indian tribe). Binding the abdomen is a common expedient. Various charms are in vogue and one cure is to make the woman swallow a spoonful of her own blood. In Annam post-partum hæmorrhage has been treated by laying the patient on her back while another woman treads on the abdomen, thus giving violent massage with her feet. Or she may be violently dragged by the hair. Cold affusion is sometimes used, or heat may be applied to the genitals till the pubic hair is singed. As the result of such treatment, of which the above are but a few examples, falling of the womb is very common.

The puerperal period.—With the idea that something must be done after delivery to restore the womb to its place we find amongst certain tribes such measures as massage and compression, various vaginal injections, the application of hot stones to the abdomen, or even violent tamponade of the vagina (tribe in Palestine). Especially noteworthy is the very widespread practice of applying heat, smoke, or steam to the woman in the puerperal period. This may be done by digging a hole in the ground, putting in hot stones, and pouring vinegar over them while the patient sits above. Or she may be exposed near a fire or may stand or lie above it. This is often carried out so severely that the mother is badly scorched or fatally burned. She may be kept in a small hut and the heating process continued for many days, and even a whole month. Flagrant examples of this are seen in Cochin China and amongst the Siamese, in New Guinea, in some Indian tribes, and in many other places. The child may share the treatment. Milder forms of vapour baths and fumigations have been common in various parts of Europe.

Most various are the customs in regard to bathing and ablution after childbirth. Religious belief governs this to some extent. Near Cape Horn a woman was seen to take four sea baths on the day on which she was confined. In another tribe we read of a woman being confined on the bank of a river and taking a plunge in the water immediately after. Others are washed two or three times daily, whilst on the other hand we find that all washing may be postponed for 14 days or more. Various medicated solutions may be used for the ablutions of the puerperal period. In Turkestan the woman after delivery has been known to be treated by wrapping the loins and abdomen in the skin of a black sheep just flayed alive, while the skin of a hare recently killed enwrapped her feet. To feed the woman after delivery on fluid or exclusively vegetarian diet or on some form of broth is very common. The most brutal practice we read of in this connexion is the refusing of drinks to the woman after delivery. In Malacca they may not drink cold water for 14 days. Among the Hindus, for instance, the custom is found of allowing the woman to hunger and thirst for five days, giving only some dry rice, and this in spite of the heat. This withholding of water even accompanies the barbarous treatment by scorching fire of which I have spoken. Sometimes women are made to drink urine. The idea that water is harmful and must be given in very small quantity is a barbarous notion, of which we have scarcely shaken ourselves free in the treatment of fever and post-operative thirst. Childbirth usually takes place in more or less seclusion, and it is a practice somewhat widely diffused to erect a special hut either near the house or at a considerable distance, say in the shelter of a wood, where the woman may pass the days of her lying-in, her husband being more or less attentive to her requirements or more or less completely neglectful of her according to local custom. On the other hand, the confinement may take place *coram populo*, with a crowd of interested spectators, who may contribute invocations or encouraging cries (Loyalty Islands).[2] Space forbids extending this article further, but fuller details will be found by the student in the authorities indicated. In India the education and provision of native midwives are promoted by such excellent institutions as those founded by Lady Dufferin and others. Many mission hospitals are doing similar work in various parts of the world. I know that it has been found in some parts of China that native Chinese women when properly trained are very apt to learn and make excellent midwives who can even use forceps with

(5) Colloid Carcinoma of the Colon from a case of Colectomy; and (6) Calculi from the Female Bladder.—Dr. Gilbert T. Beatton read notes on a case of Neurasthenia.—Dr. J. Metcalfe read notes on a case of Ureteric Calculus, with skiagram.—Mr. W. H. Horrocks read a paper on the Classification of Appendix Abscesses. He said that so much had been written about appendicitis that it seemed almost futile to attempt to say anything fresh about this condition. The anatomy and pathology had been fully discussed, and after the numberless cases which had come under observation the time seemed to have arrived when some classification of the different forms of appendix abscess might with advantage be attempted. In carrying out this idea the subject would be approached from its clinical rather than its pathological aspect. The first point to which he would call attention was the significance of the tender point lying in the line between the anterior superior spine and the umbilicus known as McBurney's point. This tenderness was generally present in appendicitis, but it was obvious that it did not indicate the position of the part of the appendix most affected. The appendix varied greatly in position. It might lie transversely across the iliac fossa, point downwards, towards the internal abdominal ring, or lie behind or outside the cæcum. Yet in all these cases there was tenderness over McBurney's point. This point really marked the attachment of the appendix to the cæcum, where the mesentery contained the lymphatic glands which became inflamed and tender. Hence this point gave no indication as to the position of the acute disease. Some years ago Sir F. Treves pointed out that a ridge might be felt crossing the appendix line in chronic appendicitis. This in some cases was mistaken for a thickened appendix as it was tender on palpation. Sir F. Treves pointed out that this ridge was probably the ileo-cæcal valve, and certainly not the appendix. On examining the blood-supply of the appendix two arteries were usually found, one of which ran along the free margin of the mesentery and the other near the attachment of the appendix to the cæcum. Generally from one-fourth to one-third of an inch of the termination of the appendix was without mesentery. This part was most subject to perforation. In other cases a kink occurred from adhesions or stricture about midway in the appendix and perforation might occur less commonly in this position. For purposes of classification appendix abscess might be grouped into three divisions. In all three cases the appendix lay in a plane behind the intestines, attached to the posterior wall of the peritoneum or in some rare cases to the under surface of the intestinal mesentery. Group I.—In which the appendix lay transversely across the iliac fossa so that its tip approached the brim of the pelvis. This was, perhaps, the commonest form. The small intestines matted together by plastic lymph formed a large tumour. There were marked local peritonitis and swelling of the abdomen. The bladder was frequently affected, there being pain and frequency of micturition. The abscess formed in the iliac fossa near the brim of the pelvis and might remain there, or it might gravitate into the pelvis occupying a position between the bladder and the rectum. Such abscesses might point by coming forwards between the coils of intestine to the anterior abdominal wall, usually near the outer margin of the rectus muscle, about a hand's breadth above the pubes. This form of appendicitis was the most dangerous from its liability to cause general peritonitis or to burrow among the organs of the pelvis. In this form examination per rectum was most valuable. Group II.—Where the appendix lay in the iliac fossa as a direct continuation of the cæcum. The affected part of the appendix lay usually near the internal abdominal ring. This form was not generally characterised by a large abdominal tumour. The abscess was frequently of small size and could be quite readily felt above, and parallel to, Poupart's ligament. The tendency of this abscess was to follow the cord along the inguinal canal. It was the least dangerous form of appendix abscess. Very often this form of abscess discharged into the cæcum and so cured itself. Group III.—Where the appendix lay between the layers of the cæcal mesentery or on the outer side of the colon. This was the most obscure form of appendicitis. It was attended by no definite tumour. The pain and tenderness seemed to travel upwards. The risk of general peritonitis was very slight, but on the other hand there was a tendency for the formation of subdiaphragmatic abscess with secondary empyema of the right side. There was often œdema of the skin of the right loin. In dealing with such abscesses there was considerable difficulty and a deep dissection might be required.—A discussion followed the paper and Mr. Horrocks then replied.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 17th, Dr. J. Walker Downie, the President, being in the chair.—Dr. G. Burnside Buchanan reported a case of Extensive Injury to the Brain. The patient sustained a compound fracture of the skull from a block of wood falling on his head. There was a large irregular wound about the right parietal eminence. Some of the fragments were depressed under the edge of the fracture. A splinter of wood about one inch by a quarter of an inch thick was imbedded in the brain. There were much effusion around and considerable hæmorrhage from the wound. He was not entirely unconscious. The left side of the body and face was paralysed. Loose fragments of bone and the piece of wood were removed. Detached brain tissue and gritty particles were removed and the wound was packed with iodoform gauze. Anti-tetanic serum was given. The wound healed slowly without suppuration but a large quantity of necrotic brain matter escaped. He regained slight power over the leg. Sleeplessness and restlessness were very troublesome and could only be controlled by morphine. The leg and facial paralysis made marked improvement but the mental condition deteriorated.—Dr. A. N. McGregor described a Method of Recording the Efficiency of the Discharge of Urine per Urethram. He considered the estimation of the size of the urethra from casts, as done by Reybard, and the use of the urethrameter of Otis, Luis, &c., did not give the rate of discharge in a given case, which was the chief point of importance. His method was to get the patient to measure the urine passed during five seconds without voluntary exertion and in similar circumstances from day to day. These results recorded on a chart gave a permanent record of variations in the efficiency of urination. A number of charts were shown and demonstrated the more lasting effects after moderate dilatation as compared with extreme dilatation. Charts from normal cases were also shown.—Dr. W. S. Syme showed: 1. A boy, aged six years, operated on for Septic Sinus Thrombosis consequent on Middle-ear Disease. There was a small carious opening into the mastoid antrum on admission. The whole mastoid process was carious. At the operation this was cleared out and *the lateral sinus was exposed.* Its wall was covered with unhealthy granulations. Three days later symptoms of septic infection developed. The sinus was opened and a thrombus was found adherent to the inner surface. The internal jugular was tied. Progress was slow but progressive. 2. Patients operated on for Diseases of the Accessory Sinuses. Intranasal treatment should be given a good trial first. Extensive operations should be performed externally and the extent of operation depended on each individual case. The sphenoidal sinus could be opened externally (the Killian operation), by way of the maxillary antrum, by the naso-pharynx, or by the anterior nares. The last method was generally preferable. 3. A case where part of the Root of the first Upper Right Molar was removed from the Maxillary Antrum into which it had been driven six years before as the result of an unsuccessful attempt at extraction.

THE KING AND THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.—Excellent photogravures of the portrait of the King, which was painted by Sir Luke Fildes, R.A., by His Majesty's command, for the Royal College of Physicians of London, of which corporation His Majesty is an Honorary Fellow, can now be obtained from the Berlin Photographic Company, 133, New Bond-street, London, W. The portrait represents His Majesty, to use the words of the publishers of the photogravure, "not in the uniform of a soldier, nor as the head of the State, but in that garb to which his fine presence lends fresh dignity—namely, as the First Gentleman of the Realm." An advanced proof of the engraving was submitted to the King, when the publishers were fortunate in finding that they had secured His Majesty's approval. Artist's proofs on Japanese paper, signed by the artist, and limited to 300 impressions, are now to be purchased priced at 5 guineas. India prints will be published at a later date at the price of 1 guinea each, and members of the medical profession will receive special consideration from the publishers diameter; the inguinal glands were hard but easily moveable on each side. There was no urethral stricture. He was treated with antisyphilitic and cardiac remedies, chiefly sodium iodide and tincture of strophanthus, and considerable improvement occurred. The ulcers, which were dressed aseptically, healed rapidly, the swelling in the leg diminished, and the hepatic tenderness disappeared. The right inguinal glands still remained hard but his tongue showed more tremor on protrusion a few weeks after the ulcers had healed. On going into the water-closet one evening he became giddy and fainted, and though he rallied for a little time he died half an hour afterwards.

I am indebted to Dr. W. Lind Walker for his assistance in the post-mortem examination which revealed the following conditions. The basal arteries of the brain were markedly atheromatous, thickening of the arterial wall being noticeable in the anterior cerebral; no sign of cerebral or other hæmorrhage was present. The cerebral substance was so soft as to break down on touching slightly with the finger and was consequently not examined microscopically. The brain weighed 49 ounces. The right lung presented a calcified mass at the apex of about the size of a pigeon's egg. The heart weighed 11 ounces. The pericardium was distended with post-mortem clot. The coronary arteries were calcareous in character; the left one was ruptured 1½ inches from the aorta; at the seat of rupture was a small node of pale yellowish coloured material which extended about 1¼ inches into the myocardial substance, which was hypertrophied and around it the tissue was of fibrous consistency and tough under the knife. On the pericardial aspect the necrotic changes appeared to have involved the artery which lay on the gumma; the arterial wall where ruptured presented a star-shaped fissure. The aortic valve was thickened at the base of each cusp; the columnæ carneæ showed signs of fatty degeneration. The liver was congested. Nothing worth recording was found in the examination of the other organs.

Remarks.—Signs of marked distension of the pericardial sac were found on the occasion of the patient's collapse, and gentle percussion revealed dulness extending up into the second left intercostal space; the cardiac sounds were muffled and the respirations were stertorous in character; the pulse was imperceptible at the wrist. When found in the heart gummata are usually multiple and often of cartilaginous-like consistency; only the one described was found in this case. Virchow has described a case in which at the same time was found syphilitic disease of the testis; in the above case the testicles were not involved, though there were pigmentation on the glans penis and a caseating node in the tibia and inguinal glands. Aitken recorded in his "Science and Practice of Medicine" (seventh edition) how there used to be in the Army Medical Department at Netley two preparations showing gummata of the heart—one from a soldier, 24 years of age, who had been under treatment for nine months for venereal ulcers; in the above case some of the ulcers had healed only three weeks before the patient's death. Gummata are usually found in the septum between the ventricles.

Salisbury.

A CASE OF ACUTE ASCENDING PARALYSIS WITH RECOVERY.

BY C. WILFRED VINING, M.B., B.S. LOND.,
HOUSE PHYSICIAN, ST. MARY'S HOSPITAL, PADDINGTON, W.

THE patient in the following case was a well-nourished muscular man, aged 24 years, who was admitted into St. Mary's Hospital on Dec. 2nd, 1907, under the care of Dr. Sidney P. Phillips. He felt quite well up to Nov. 28th when he experienced a feeling of weakness in the calves of his legs. He started out to work the next day, but while on the way he had to return home owing to the increasing weakness. On the 30th he noticed blurring of vision on reading the newspaper. On Dec 1st the weakness of his legs was still more pronounced and he could not articulate distinctly. On the following day he could not stand without assistance and his arms were also weak. He had fallen off a ladder on to his feet a week previously to the onset of the symptoms but experienced no inconvenience at the time.

On admission he was unable to walk but could just stand with assistance. There was also considerable weakness in the muscles of his arms, especially in the extensors. The muscles were flaccid but not wasted and there was an absence of all reflexes, including the palatal reflex. The respiratory, abdominal, and intercostal movements were normal. There was slight right-sided facial weakness. The external muscles of the eye were normal. The right pupil reacted sluggishly to light and to accommodation and was somewhat larger than the left. The fundi were normal. Speech was a little indistinct, apparently due to difficulty in the movements of the tongue, and there was slight difficulty in swallowing. There was no alteration in the sensory functions except that he appeared to have lost sensation of the palate. His mouth was dirty with sordes on the lips. Cultures were obtained from the mouth and throat, but nothing resembling a diphtheritic organism was found. A lumbar puncture was performed soon after admission and 15 cubic centimetres of clear fluid with a few whitish floating particles were obtained. In this an organism having the appearance of a streptococcus was found but no growth could be obtained on culture media. The patient was given five minims of liquor strychninæ hydrochloratis every four hours and at a later period hot-air baths were administered. The muscular weakness quickly increased and on Dec. 7th there was evidence that the diaphragm was commencing to be paralysed and chest expansion was reduced to a minimum. Rhonchi appeared in both lungs with marked cyanosis and difficulty in swallowing. There was now complete paralysis of the legs, he could barely move his arms, and there was incontinence of urine and fæces. The outlook now seemed hopeless. The pulse-rate increased, reaching 100, and the cardiac apex passed from a point half an inch internal to the nipple to a quarter of an inch external to it. The strychnine had been stopped on Dec. 4th but it resulted in the condition becoming so much worse that on the 8th it was resumed in doses of seven minims, quickly increased to 10 minims, every four hours, and oxygen was also administered. On the 8th there were signs of improvement, the chest movements increasing and the difficulty in swallowing lessening. From the 8th to the 15th his condition remained stationary, except that some muscular wasting became evident. There were now also some slight, rather indefinite alterations in sensation over his legs, especially the right one, and he complained at times of severe pain in his knees. Sensation for heat and cold was normal. These only lasted a few days and were apparently the only sensory disturbances present during the course of the illness, except the anæsthesia of the palate mentioned above. On the 15th the diaphragm descended during quiet respiration, and from this time onwards he steadily improved. There was never any pyrexia. On Jan. 24th he could walk without assistance, had perfect control over the sphincters, and felt very well. There was no residual paralysis, but muscular wasting of the limbs was still marked and knee-jerks were still absent. The electrical reactions taken during the course of the illness showed no reaction of degeneration, but there were reduced response to faradism and no response to galvanism. Later there was reaction to both, but less than in a normal person. During his recovery galvanism and later faradism were applied daily.

The interest of this case consisted in the recovery from what appeared to be a severe example of Landry's paralysis and which when the diaphragm showed signs of paralysis threatened to be speedily fatal. The diagnosis lay between (1) diphtheritic paralysis, (2) Landry's paralysis, and (3) a toxic paralysis affecting the anterior cornua or nerves. There was, however, no evidence or history either of diphtheria or of any exposure to such toxic influences as syphilis, gonorrhœa, lead, or alcohol, and on the whole the case seemed to correspond better with Landry's acute ascending paralysis than with any other disease. Against this diagnosis there may be urged (1) the anæsthesia of the palate and the slight sensory disturbance of the legs, and (2) the fact that the parts affected were not altogether anatomically in succession from below upwards, but in Landry's own description of the condition diminution in cutaneous sensibility over the distal parts of the limbs is mentioned and the arms and face were affected before the legs were completely paralysed. In the present case strychnine appeared to have a very beneficial effect. I am indebted to Dr. Phillips for permission to publish these notes.

ROYAL INSTITUTION.—At a general monthly meeting of the members of the Royal Institution held on Monday afternoon last it was announced that the managers had appointed Dr. Kenneth Robert Hay as medical officer to the Royal Institution in succession to the late Mr. Woodhouse Braine who had held the appointment for 36 years.

overloaded with descriptions of detail which can only be properly appreciated when they are seen actually performed. But a young nurse who has mastered the contents of such a book as this will be in a position to appreciate her practical instruction more intelligently and so to derive an added advantage from it. That the practical side of the nurse's training has been in the author's mind is apparent from the fact that she prefaces the book with an excellent scheme of demonstrations for adoption by those who are responsible for the practical instruction of probationers, which we commend to the notice of those matrons of the smaller hospitals who are engaged personally in lecturing to their junior staff. We need not discuss the matter of the book, as we have already indicated its range, and the teaching is laid down on the lines of accepted authority. There are one or two words which are strange to English ears. How many of our readers know what is meant by "gastric gavage" (*sic*) or an "alcohol sweat"? But we can forgive much in the case of an American writer who spells "technique" as it ought to be spelt.

The Spectroscope: An Intermediate Text-book for Practical Chemists. By T. THORNE BAKER, F.C.S., F.R.P.S. London: Baillière, Tindall, and Cox. 1907. Pp. viii.-130, with three coloured and 63 plain illustrations. Price 5*s.*—The practical applications of the spectroscope are extremely numerous and it is indispensable in such medico-legal inquiries as involve the identification of blood stains. Our issue of Jan. 4th also contained a reference to its use in determining the nature of the light emitted by photogenic bacteria. The hæmoglobin of blood produces dark absorption bands in the spectrum and the test is usually accomplished by means of a direct-vision spectroscope adapted to a low power of the microscope. In the present volume there is no actual mention of blood but all the apparatus necessary for exhibiting the various spectra of hæmoglobin are so fully described that it deserves the attention of medical readers interested in this subject. The book is divided into nine chapters, of which the first deals mainly with optical principles and the second with the constructional details of various instruments in which equiangular prisms, diffraction gratings, combinations of prisms and gratings, and compound direct-vision prisms are respectively employed. Chapters III., IV., and V. describe the adjustments and practical use of the apparatus and the interpretation of continuous and bright-line spectra obtained from various sources, including phosphorescent bacteria. Chapters VI. and VII. give a satisfactory account of spectrum photography as applied to the determination of the wave-length of unknown lines, to simple methods of analysis in inorganic chemistry, and to the colour-sensitising of photographic plates. Chapters VIII. and IX. are devoted chiefly to the relations which the bands and lines of the spectrum bear to questions of chemistry, chemical physics, and chemical constitution. Students working with the spectroscope in chemical and physiological laboratories will find this a very serviceable book.

The Science Year Book, 1908. London: King, Sell, and Olding, Limited. Price 5*s.* net.—This work of reference and diary will be found useful by workers in all departments of science. In the diary a separate page is devoted to each day of the year and at the top of each page various astronomical facts are given and space is provided for recording the barometer, wind direction and pressure, rainfall, and so forth. The reference portion of the book contains a great deal of information dealing with astronomy, physics, chemistry, meteorology, and other departments of science, and gives facts and formulæ of every-day utility. Among the features of the work is a summary of the progress of science during the year 1907, a glossary of recently introduced scientific terms, names of periodicals, and a list of scientific societies. Brief biographical notes of prominent scientific men are also included. Some new tables have been added to the present issue, among them being a useful table of four place logarithms.

JOURNALS AND MAGAZINES.

The St. Mary's Hospital Gazette for January contains a very interesting paper by Dr. W. H. Willcox on the Medico-legal Importance of Wounds produced by Firearms in which he deals with certain points connected with the laws relating to such wounds, the causes of death resulting from them, and the types of wounds produced by revolver or pistol, rifle, and shot-gun wounds respectively. Illustrative cases are quoted, including the Whiteley, Moat Farm, and Chorley Wood murders. The paper is a useful contribution to medico-legal literature. Much of the remainder of the *Gazette* is devoted to an account of the Christmas doings at St. Mary's, which were wound up by two performances of *The Private Secretary* in the out-patient hall by the residents for the benefit of patients and nurses. The production seems to have been very successful. This number also includes a photographic supplement illustrating the Students' Cot, supported by St. Mary's students.

The Illuminating Engineer.—The first number of this new monthly journal contains an interesting article on Vacuum Tube Electric Lighting by Professor J. A. Fleming, F.R.S., of University College. One of the disadvantages of lighting by the ordinary incandescent filament is the extreme harshness of the shadows, the sharp contrasts being very trying to the eyes. If the shadows are softened by frosting the globes there is naturally great loss of efficiency. Another disadvantage is the great richness of the light in ultra-violet rays which are useless for illumination and are responsible for most of the damage done to the eyes by electric light. There is good reason to believe that both of these drawbacks may be to a very large extent removed by the new form of illumination. The method has been used for some time in America but has received little attention here. It may, however, be seen at work in the courtyard of the Savoy Hotel. It has long been known that light could be obtained by passing a high tension current through rarefied gas. The gas undergoes absorption with diminution of pressure. This practical difficulty has been overcome by the invention of an ingenious valve by Mr. Macfarlane Moore. By Moore's method a tube one and three-quarter inches in diameter and of any length up to 200 feet can be made incandescent. For ordinary purposes nitrogen is the best gas and it can be obtained easily from the air. The light has a rich golden hue, or with carbon dioxide whitish blue. From the hygienic point of view it is desirable that experiments should be made to determine the quality of the rays emitted in different circumstances. Professor Fleming, from experiments carried out at the Savoy Hotel, has shown that the illuminating power is 9·6 candle-power per foot. The intensity of light from such a linear source varies approximately inversely as the distance, not as the square of the distance as with ordinary methods. Hence the illumination three feet above the ground is equivalent to that of about 100 16 candle-power lamps equally distributed over the ceiling at the same height above the ground as the tube. The light intensity is directly proportional to the voltage and is therefore much more constant than with glow lamps. Both initial cost of installation and working expenses are less. With carbon dioxide in the tube tinted surfaces appear as in daylight, so that artistic work can be carried on as by day. The new journal contains articles on illumination and eyesight, with special reference to the eyesight of school children and the effectual lighting of schoolrooms, on the protection of the eyes from ultra-violet rays, and so on. They clearly established that fibroids are particularly liable to undergo degenerative changes during pregnancy; why this is so we do not know. Necrobiosis is generally regarded as the result of vascular lesions, but as to what is the nature of these lesions, or what are the factors which determine their onset we possess no certain knowledge. The process is, as far as we know, neither infective nor thrombotic, and it is difficult to explain why it should occur at a time when the vascular supply of the uterus is richest.

The onset of the symptoms was strikingly sudden. At the time of operation I looked carefully for torsion of either the tumour or the uterus, but I could find none. There was extensive local peritonitis and this may account for the severity of the pain in this case, but a necrobiotic fibroid is often *per se* a painful tumour, and in some instances where the pain has been great no adhesions or other evidences of peritonitis have been found. The constitutional symptoms, the raised temperature, the frequent pulse, the furred tongue, and the loss of flesh are evidences of the profound toxæmia associated with the change. Finally, I would draw attention to the fact that during the involution of the uterus the fibroids in its walls became smaller.

Wimpole-street, W.

ERRATUM.—In the last sentence of an article by Dr. A. Eddowes and Dr. J. G. Hare published in THE LANCET last week (p. 232) an error has occurred. It was Dr. M. K. Hargreaves who was speaking and not Dr. Eddowes or Dr. Hare, and the sentence should run: "In a second case Dr. Hargreaves is indebted to Dr. Alan B. Slater for carrying out the treatment at the patient's own home."

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF ACUTE PULMONARY ŒDEMA.

BY J. M. PEARSON, M.D.

IT is somewhat curious that the English-speaking medical profession should have had to wait until the early years of the twentieth century for a clear recognition of such a well-defined dramatic affection as acute pulmonary œdema. A very typical case occurred in my practice in the years 1901–02 and, like Dr. Leonard L. B. Williams, I searched, but searched in vain, through a somewhat limited field, it is true, for any adequate mention of such a condition.

The patient was a woman about 50 years of age, stout, ruddy, and energetic. The most diligent search between attacks, for she had several, failed to reveal anything grossly wrong with either heart or kidneys. The subject of arterial tension had not then risen on my medical horizon. The attacks took place invariably at night—two in a month at one time and then four or five months' freedom. She would retire to bed early in apparently the best of health, to be awakened soon after midnight with shortness of breath. By the time I arrived on the scene she would be sitting up in bed quite unable to speak, with her face livid, beads of perspiration on her forehead, her chest heaving for breath, and a pint or more of frothy, slightly blood-tinged sputum in the basin held in front of her. The family got into the way of applying hot things to her chest and back, and on general principles I used to give strychnine hypodermically. The pulse was small and rapid. In an hour or less the severity of the attack would be over and she would be put back to bed, well propped up with pillows. Next day all would be well and two or three days would see her at her usual occupation, minding a small shop. From first to last the condition went on for 12 months, and I have records of five attacks during that time. Finally the end came, the old lividity was there but the weakened or tired respiratory muscles failed to respond with their accustomed vigour, and after a few sighing breaths she died two or three minutes after I reached her bedside. There was no necropsy and I left the case as mystified at the end as at the beginning. I noted that the serous fluid appeared to be poured into the lungs practically all at once, and that when it was cleared away there was no continued secretion. I also learned that the patient ought to be kept in an upright posture, which is the attitude the patients naturally tend to assume.

Blood-letting might suggest itself but reflection shows that all the mischief is done before the medical man arrives. The bleeding has already been accomplished and certainly the pulse has none of the attributes usually associated with the necessity for the operation.

Vancouver, British Columbia.

THE FREE USE OF AMYL NITRITE IN PULMONARY HÆMORRHAGE.

BY ALEXANDER LUNDIE, M.B., CH.B. EDIN.

IT fell to me three years ago to treat an extremely profuse pulmonary hæmorrhage, and after very much misgiving about taking it in hand at all I determined to use amyl nitrite. The results were such as I never regretted, but I was personally rather sceptical about the rôle of amyl nitrite in their production until I saw articles on the subject in THE LANCET in 1906. My reason for using this agent may therefore be of interest to others. I knew at that time of the lung reflex of Abrams but thought it had no bearing on the subject. I thought, like an ancient Greek historian, that it was entirely a matter of hydrostatics that had to be dealt with. Recollecting the story of a Greek, probably one of the "ten thousand," wounded in battle and bleeding profusely till he fainted and remained long unconscious, his wound becoming staunched meanwhile, so that he eventually recovered, I determined to imitate this condition, seeing my case was just as desperate. I hoped to lower the blood pressure and bring about a condition temporarily like surgical shock, trusting to clotting taking place meanwhile in the wound. I accordingly administered amyl nitrite on a towel like chloroform without regard to official dosage, guiding myself entirely by the pulse and the general condition. It quickly produced slight transient anæsthesia, with an insignificant preliminary stage of excitement. The pressure in the radial artery was very much lowered, the pulse being almost imperceptible, and I stopped at this stage as the respirations became very shallow. The results were good and a satisfactory recovery followed.

Dalmuir, Dumbartonshire.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

MEDICAL SECTION.

The Kinematograph in Medicine.—Pathology and Treatment of Chronic Constipation.

A MEETING of this section was held on Jan. 28th, Dr. S. J. GEE, the President, being in the chair.

Dr. H. CAMPBELL THOMSON gave a demonstration of the Use of the Kinematograph in Medicine. He showed films demonstrating certain gaits in nervous complaints. These will be found described and illustrated in the first number of THE LANCET of this year.[1]

Dr. A. F. HERTZ read a paper on the Pathology and Treatment of Chronic Constipation. He said that the treatment of chronic constipation was experimental. One method was tried and then another until by chance the method suitable to the individual case was discerned. That unsatisfactory state of affairs was due mainly to the fact that it had hitherto been impossible to determine the actual part of the intestines in which the delay causing the constipation occurred. In the case of medicinal treatment the difficulty was made greater by the lack of trustworthy information as to the relative effects exerted by any given purgative on different parts of the alimentary canal. Hence there were no rational guides to indicate what drug, if any, should be employed in a case. It seemed probable that enemata would prove of value in those cases in which the delay occurred somewhere between the splenic flexure and the anus. For that reason it might perhaps be assumed that sherry; they were as follows: alcohol, by volume, 20·24 per cent.; extractives, 5·30 per cent.; mineral matter, 0·49 per cent.; volatile acidity, reckoned as acetic acid, 0·084 per cent.; fixed acidity, reckoned as tartaric acid, 0·33 per cent.; and sugar, 4·06 per cent. The ethers amounted to as much as 0·68 gramme per litre. We have before referred to the fact that the amount of ethers in sherry exceeds that found in other wines. As a stimulant, therefore, sherry must be placed in the front rank. The wine belongs to the description of a Palo Cortado sherry which, although of the Oloroso type, is delicate in flavour. From the point of view of the connoisseur this sherry will be regarded as a really elegant wine, while its satisfactory characters in general commend it for medicinal use when a stimulant is ordered by the medical man.

---

[1] THE LANCET, Jan. 4th, 1908, p. 12.

ALKURIS TABLE WATER.

(ALKURIS, LIMITED, 37, SHEEN-ROAD, RICHMOND, S.W.)

We can well believe that this excellent table water is manufactured with care having regard to its purity as shown by our analysis. The water is clear and bright and pleasantly sparkling, while its taste is satisfactory, being very "clean" on the palate. The water is further slightly mineralised and contains the citrates of potassium and lithium and the bicarbonates of sodium and potassium, together with a small quantity of sodium chloride. According to our analysis the total salts present amounted to 1·39 grammes per litre. We found amongst these 0·28 gramme of lithium citrate, 0·40 gramme of alkaline carbonate, and 0·42 gramme of common salt per litre. The water shows an excellent condition of organic purity, as might be expected since it is carefully distilled. The water is obviously useful when a course of alkaline treatment is indicated. Its free administration is calculated to preserve an alkaline state of the blood, and alkaline table waters in general are often valuable in gastric catarrh and favour the excretion of waste toxic products.

V.V. (VIS VITÆ) BREAD.

(V.V. BREAD COMPANY, LIMITED, 16 TO 32, BREWERY-ROAD, LONDON, N.)

We are always glad to recognise any attempts to make bread a palatable and nutritious article. Nowadays palatability and nutritive value are too often sacrificed in favour of appearance; the loaf must be spotlessly white without regard at all to its dietetic properties. The V.V. loaf is both palatable and nutritious. It has not that tastelessness which characterises so much of the bread of the present day, while doubtless owing to the use of good flour and of a specially pure barm it keeps fresh for a much longer time than ordinary bread. The flour used is clearly of high quality, since our analysis of the bread shows a maximum proportion of proteins for wheat flour; the mineral matter, too, is present in equally satisfactory proportions. The flavour of bread is an important factor in dietetics and it is much to be deplored that the bulk of the bread offered to the public is practically tasteless. The flavour to which we refer is difficult to describe, as are all flavours, but everyone knows the peculiar attractive nutty flavour of the unsophisticated bread made in the country home. Such bread as a rule is neither colourless nor flavourless, nor should it be. We have examined several varieties of V.V. bread and have found them to be most satisfactory; they are palatable, and largely because they are palatable they are readily digestible, for a good appetising flavour invariably invokes good digestive power.

PETOL PREPARATIONS.

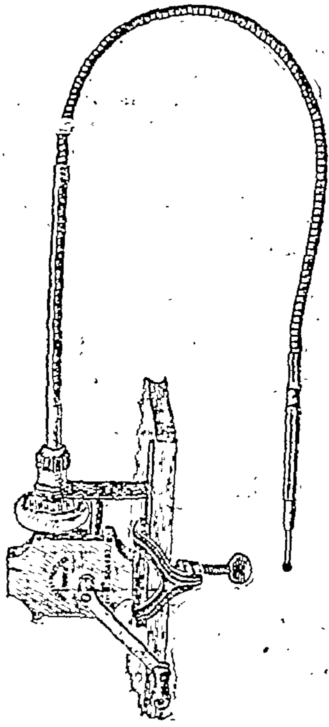
(P. S. SYNDICATE, ST. ANDREW'S WORKS, ST. ANDREW'S-STREET, BETHNAL GREEN, LONDON, E.)

Petol is an interesting oily substance obtained from peat. It does not appear to contain bodies of the phenol type but certain hydrocarbon oils which have a germicidal value. "Petol fluid" is a brown turbid mixture with a characteristic smell. It is alkaline to test paper and on adding hydrochloric acid to the fluid there is a separation of brown oils. Petol appears in a number of preparations intended for the purposes of antiseptic treatment. There are, for instance, petol soap, salve, disinfectant powder and fluid, and suppositories. While there is evidence of petol having marked germicidal power it is non-corrosive and non-poisonous. It has been used, it is said, internally in typhoid fever. It appears also, in the form of ointment, to be an excellent antiseptic and healing application for wounds.

New Inventions.

A PORTABLE SURGICAL ENGINE.

THE accompanying illustration represents a manual and portable surgical engine designed to perform the work of the ordinary surgical motor in a private house. The most attractive feature of this little machine is its portability—the handle, flexible spindle, and fixation clamp are all detachable and can, together with the body of the engine, be most easily accommodated in a hand-bag of the size of the ordinary midwifery bag. The construction is such that it can be clamped to any table or projecting ledge conveniently near the surgeon and the most unskilled person can supply the motive power. Practitioners are mostly agreed as to the value of the burr in the performance of mastoid operations; the difficulty hitherto has been to obtain a mechanism which would be serviceable anywhere and at the same time capable of being carried easily. This instrument, made at my suggestion by Messrs. Mayer & Meltzer, of London, I think supplies the want.



NEIL MACLAY, M.B., C.M. Glasg.,
Honorary Assistant Surgeon, Throat and Ear
Hospital, Newcastle-on-Tyne.
Wallsend-on-Tyne.

THE FIRST AID SNAKE-BITE OUTFIT.

A GREAT many deaths are caused every year in tropical countries by the bites of venomous snakes and more than 30 years ago the late Sir Joseph Fayrer recommended the local application of permanganate of potassium as an antidote. On account of the rapidity with which death follows a bite the treatment to be of any avail must be employed immediately. Sir Lauder Brunton a few years ago accordingly devised a form of lancet set in a wooden handle, one end of at its entrance to the ocular cleft to form the vitreous. The child was six months old and was admitted to hospital under Mr. W. I. Hancock. The mother had noticed that the left eye was very small from birth but the child had no other deformities. There were no signs or history pointing to congenital syphilis. The right eye was normal in size and there was nothing abnormal in the fundus. In the other eye there was a well-marked pupillary membrane. Behind the lens, which was clear, was a yellowish-white reflex with vessels on it similar to that seen in glioma and pseudo-glioma. As diagnosis was doubtful enucleation was performed and the child made a good recovery. The eye was hardened in formol and sections were cut antero-posteriorly. The optic nerve was removed and cut in transverse section. The globe measured 15 millimetres antero-posteriorly, 10 vertically, and 10 horizontally. The sclera showed no change. The angles of the anterior chamber were imperfectly formed owing to incomplete separation of the iris from the back of the cornea. The ciliary body was free from signs of inflammation. Behind, and lying on the pars plana, was a large mass of pigmented and unpigmented cells derived from the ciliary body. Towards the outer part was an attempt at alveolar formation. The retina was detached but did not stop at the ora serrata but passed close behind the ciliary process, where it was continuous with the anterior layers of the epithelial cells and the mass mentioned. The lens was thickened and thrown into folds and consisted principally of neuroglial tissue but possessed no regular structure. The retinal detachment was of earlier date than the hæmorrhage separating it from the choroid. The choroid presented a coloboma below but the blood-vessels were not thickened. The lens showed a condition of posterior lenticonus. The central artery was well developed and showed no changes in its walls. Generally in such cases the distortion of the posterior part of the lens was associated with a persistent hyaloid artery or a gap in the posterior part of the lens capsule, but neither of those conditions was present in this case. There was hypertrophy of pigmented and non-pigmented epithelial cells, the reason of which it was difficult to understand, unless it was due to nutritional disturbance in the line of separation of the two layers in the primary optic vesicle.

Mr. L. J. PATON read a paper on Optic Neuritis in Cerebral Tumours. The paper was based on the records of 252 consecutive cases seen at the National Hospital, Queen-square. In 202 of those the localisation of the intracranial tumour was definite, and 148 were confirmed by operation or post mortem. Of the 202 cases, 38 (or 18·8 per cent.) had no neuritis; 12 had only very slight neuritis, the edges being at no period completely blurred; 27 were in a condition of post-neuritic atrophy when first seen; and the remaining 125 had marked neuritis. Mr. Paton pointed out that the great majority of cases without neuritis occurred in subcortical and pontine tumours. The percentage of cases with no neuritis in tumours of those two areas was respectively 38 and 43·5. He pointed out, further, that when subcortical tumours developed optic neuritis it almost invariably indicated that the growth had involved either the grey matter of the cortex or the grey matter of the base, and that when pontine tumours developed optic neuritis it practically, without exception, indicated very definite involvement of the cerebellum. He showed that in tumours of the cerebral cortex the intensity of the neuritis seemed to vary inversely with the distance of the tumour from the anterior pole of the middle fossa. He adduced evidence to show that the nature of the growth had little, if any, influence on the development of optic neuritis, except in so far as the nature of the growth might influence its position. He stated that the figures showed that very little reliance could be placed on differences in the intensity of the neuritis as indicating on which side the tumour developed and that in the cases of frontal and of cerebellar tumour neuritis was just as frequently most marked in the optic disc of the opposite eye as it was in the eye on the side of the tumour. The neuritis commenced more frequently in the eye on the side of the tumour than in the opposite eye, but even here the preponderance—23 to 13—was not sufficiently marked to make the sign one of much value for localising purposes He described in detail the development of the macular changes seen in intense cases of tumour neuritis, and showed that these changes were most probably produced by an overflow of œdematous fluid from the much swollen disc into the nerve-fibre layer, and that the presence of very well-marked macular fans was compatible with the retention of perfectly good vision. The causation of temporary attacks of blindness, lasting from a few seconds to half an hour, was discussed and it was shown that these were probably not associated with optic neuritis, as they had been observed three times in cases where no optic neuritis developed, and in other cases these fleeting amblyopias had occurred before ophthalmoscopic evidences of disc change were present. It was suggested that these attacks were due to sudden rises in intraventricular tension, causing a bulging of the thin floor of the third ventricle, and to direct pressure on the chiasma. The attacks were invariably accompanied by increased headache and giddiness. He pointed out that there was no evidence in favour of optic neuritis in these cases being due to an inflammation descending from the basal meninges, nor was there evidence in favour of it being due to pressure of fluid in the vaginal space. The clinical evidence against it being a descending inflammation in the nerve trunks was even stronger, nor was there any more evidence in favour of the neuritis being produced locally by the action of toxin or of its being a vaso-motor phenomenon. He regarded their knowledge to be, as yet, insufficient to justify any definite theory as to the causation of optic neuritis, but a general review of the subject in its clinical aspects inclined him to the view that in so-called optic neuritis there was simply a manifestation locally of a general œdema of the cerebral tissues due to the irritation set up by the tumour as an actively growing foreign body.

The following two papers by Mr. SIMEON SNELL were, in his absence, taken as read: 1. Carcinoma of the Orbit originating in a Meibomian Gland. The case occurred in a woman, aged 63 years. In 1904 another surgeon had removed a lump from the right upper eyelid. In July, 1905, there had been a recurrence at the site of that scar reaching back to the orbit, of about the size of a walnut. This was removed with the portion of eyelid, but in June, 1906, there was another recurrence and then the eyeball was removed and the whole orbit cleared out and chloride of zinc paste was applied. Still further recurrence had occurred and the orbit was filled with a large ulcerated growth and the pre-auricular and cervical glands were enlarged. Dr. A. E. Barnes reported that it was a spheroidal-celled carcinoma and was of opinion that it had probably originated in a Meibomian gland. Mr. E. Treacher Collins corroborated this. 2 The second paper was on Coloboma of the Iris in each Eye, occurring in five generations. Mr. —— was the first person seen and he had a large coloboma in each eye, down and out. The defect was known to have existed in his grandmother, in her sister, and in his mother. Mr. —— had six children, three of whom were affected, and of these two had children—one had three children, of whom two were affected, and the other had one child who was affected. Mr. —— was the only child of his father, but his mother had, by a second husband, five children, of whom three were affected. One of these had three children, two of whom were affected. The other had one child who was not affected. In all, of 41 persons 12 were affected—five males and seven females. In the great-great grandchildren the defect was complete aniridia.

The following card specimens were shown:—

Mr. E. E. HENDERSON: Sections from case of Sarcoma developing under Calcareous Plate.

Mr. P. C. BARDSLEY: A New Form of Scotometer.

Mr. S. STEPHENSON: A case of Buphthalmia apparently Cured by the performance of Iridectomy.

Dr. L. G. GUTHRIE and Mr. MAYOU: Right Hemiplegia with Obstruction (? Thrombosis) of the Left Common Carotid and Central Artery of the Retina, with Perception of Light in the Eye.

Mr. G. H. GOLDSMITH: Optic Neuritis.

Mr. J. S. HORSFORD: Essential Shrinking of the Conjunctiva.

Mr. C. WRAY: Sympathetic Iridocyclitis.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 21st, Mr. H. Shackleton, the *President*, being in the chair.—Mr. J. Basil Hall showed: (1) A Fibroid, weighing 15 pounds, from a patient, aged 70 years; (2) two specimens of Intussusception removed by Enterectomy; (3) an Ectopic Gestation producing Torsion of the Fallopian Tube; (4) an Excised Gastric Ulcer which had produced hour-glass contraction;

sherry; they were as follows: alcohol, by volume, 20·24 per cent.; extractives, 5·30 per cent.; mineral matter, 0·49 per cent.; volatile acidity, reckoned as acetic acid, 0·084 per cent.; fixed acidity, reckoned as tartaric acid, 0·33 per cent.; and sugar, 4·06 per cent. The ethers amounted to as much as 0·68 gramme per litre. We have before referred to the fact that the amount of ethers in sherry exceeds that found in other wines. As a stimulant, therefore, sherry must be placed in the front rank. The wine belongs to the description of a *Palo Cortado* sherry which, although of the Oloroso type, is delicate in flavour. From the point of view of the connoisseur this sherry will be regarded as a really elegant wine, while its satisfactory characters in general commend it for medicinal use when a stimulant is ordered by the medical man.

ALKURIS TABLE WATER.

(ALKURIS, LIMITED, 37, SHEEN-ROAD, RICHMOND, S.W.)

We can well believe that this excellent table water is manufactured with care having regard to its purity as shown by our analysis. The water is clear and bright and pleasantly sparkling, while its taste is satisfactory, being very "clean" on the palate. The water is further slightly mineralised and contains the citrates of potassium and lithium and the bicarbonates of sodium and potassium, together with a small quantity of sodium chloride. According to our analysis the total salts present amounted to 1·39 grammes per litre. We found amongst these 0·28 gramme of lithium citrate, 0·40 gramme of alkaline carbonate, and 0·42 gramme of common salt per litre. The water shows an excellent condition of organic purity, as might be expected since it is carefully distilled. The water is obviously useful when a course of alkaline treatment is indicated. Its free administration is calculated to preserve an alkaline state of the blood, and alkaline table waters in general are often valuable in gastric catarrh and favour the excretion of waste toxic products.

V.V. (VIS VITÆ) BREAD.

(V.V. BREAD COMPANY, LIMITED, 16 TO 32, BREWERY-ROAD, LONDON, N.)

We are always glad to recognise any attempts to make bread a palatable and nutritious article. Nowadays palatability and nutritive value are too often sacrificed in favour of appearance; the loaf must be spotlessly white without regard at all to its dietetic properties. The V.V. loaf is both palatable and nutritious. It has not that tastelessness which characterises so much of the bread of the present day, while doubtless owing to the use of good flour and of a specially pure barm it keeps fresh for a much longer time than ordinary bread. The flour used is clearly of high quality, since our analysis of the bread shows a maximum proportion of proteins for wheat flour; the mineral matter, too, is present in equally satisfactory proportions. The flavour of bread is an important factor in dietetics and it is much to be deplored that the bulk of the bread offered to the public is practically tasteless. The flavour to which we refer is difficult to describe, as are all flavours, but everyone knows the peculiar attractive nutty flavour of the unsophisticated bread made in the country home. Such bread as a rule is neither colourless nor flavourless, nor should it be. We have examined several varieties of V.V. bread and have found them to be most satisfactory; they are palatable, and largely because they are palatable they are readily digestible, for a good appetising flavour invariably invokes good digestive power.

PETOL PREPARATIONS.

(P. S. SYNDICATE, ST. ANDREW'S WORKS, ST. ANDREW'S-STREET, BETHNAL GREEN, LONDON, E.)

Petol is an interesting oily substance obtained from peat. It does not appear to contain bodies of the phenol type but certain hydrocarbon oils which have a germicidal value. "Petol fluid" is a brown turbid mixture with a characteristic smell. It is alkaline to test paper and on adding hydrochloric acid to the fluid there is a separation of brown oils. Petol appears in a number of preparations intended for the purposes of antiseptic treatment. There are, for instance, petol soap, salve, disinfectant powder and fluid, and suppositories. While there is evidence of petol having marked germicidal power, it is non-corrosive and non-poisonous. It has been used, it is said, internally in typhoid fever. It appears also, in the form of ointment, to be an excellent antiseptic and healing application for wounds.

Reviews and Notices of Books.

Arterial Hypertonus, Sclerosis, and Blood Pressure. By WILLIAM RUSSELL, M.D., F.R.C.P. Edin., Physician to, and Lecturer on Clinical Medicine in, the Royal Infirmary, Edinburgh, &c. With 36 illustrations and plates. Edinburgh and London: William Green and Sons. 1907. Pp. 194. Price 7*s.* 6*d.* net.

MUCH attention has been paid in recent years to the subject of disease of the blood-vessels but in spite of this, or perhaps because of the very number of writers setting forth divergent views and using technical terms with different shades of meaning, there is considerable confusion of ideas in this field. Dr. Russell in the book before us makes a praiseworthy attempt to straighten out the tangle. As the outcome of much careful clinical observation he has formed clear ideas of the conditions met with and he appreciates the need not only of clear thinking but of defining the terms in which they are set out.

The author first draws a distinction between two affections which are often confused—atheroma and arteriosclerosis. The former, he holds, is a localised affection produced by irritation combined with degeneration; the latter is a generalised change consisting in permanent thickening of the walls of the vessels which may involve the middle coat alone or the inner and outer coats along with it. Not every vessel, however, which feels thick and rigid to the examining finger is the seat of sclerosis. The arteries are muscular tubes and as such are capable of contraction and relaxation. A contracted artery may feel thick and rigid, just as a degenerate one does. This condition of spasmodic contraction is called by the author "hypertonus," an exaggeration of the normal tone of living vessels. It may be brought about by toxic substances circulating in the blood such as are present in renal disease and if it persist owing to continuance of the cause permanent sclerosis (hypermyotrophy) ensues. Constriction of any part of the arterial system is necessarily followed by increase of blood pressure and this sequence is recognised to occur in renal troubles. Some confusion of thought seems, however, to prevail as to the point at which the raised pressure exists. The author has devised (with the assistance of Dr. Cargill Knott) a model which reproduces some of the features of the circulation and shows that the rise in pressure occurs behind the obstruction, while a fall is met with beyond it. This might, indeed, have been anticipated. The apparatus does not show, and it is the point which most needs proof, whether there is a rise of pressure *within* an artery which is constricted throughout some considerable portion of its length.

Another point on which new light is shed in this volume is the value of hæmomanometer readings in disease as measures of actual blood pressure. It seems satisfactorily demonstrated, as might indeed have been anticipated, that the wall of a thickened artery offers considerable resistance to compression and that this factor has to be taken into consideration as well as the actual pressure of the blood in drawing conclusions from the readings of an instrument which works by obliterating the lumen of an artery. It is a question, however, how far this criticism applies to such an instrument as the Hill-Barnard sphygmometer, in which the principle is the equalisation of the pressures inside and outside the vessel as shown by the degree of oscillation of the column of fluid in the instrument.

In the stage of hypertonic contraction much may be done for the patient by the administration of drugs which relax arterial spasm; the author speaks highly of erythrol tetranitrate. Even sclerotic and degenerated arteries are capable of a considerable degree of spasm and relaxation and must not be looked upon as beyond treatment. Spasm is often brought on by exaggeration of the physiological reflex by which the peripheral vessels contract after a meal coincidently with a relaxation of the splanchnic system. Proteid decomposition products, alcohol, and tobacco are also causes of arterial constriction. In the light of the views just set forth the author discusses various cerebral conditions associated with spasm of arteries and also the condition known as angina pectoris. Incidentally he makes the suggestion that the secretion of the pituitary gland may have the special function of acting on the cerebral arteries. Into these discussions we cannot here follow him.

The views enunciated in this book offer a clear and a consistent account of the phenomena of vascular disease which should give pathologists and clinicians food for thought and discussion. The book may be commended to the attention of all who are interested in one of the most important problems in the theory and practice of medicine. We congratulate Dr. Russell on a valuable piece of work.

Manual of Surgery. By H. ALEXIS THOMSON, F.R.C.S. Edin., Assistant Surgeon, Edinburgh Royal Infirmary; Surgeon to the Deaconess Hospital, Edinburgh; and ALEXANDER MILES, F.R.C.S. Edin., Assistant Surgeon to the Edinburgh Royal Infirmary; Surgeon to the Leith Hospital. Second edition, revised and enlarged, with many illustrations, mostly wood engravings. Vol. I., General Surgery. Pp. 808. Vol. II., Regional Surgery. Pp 816. London and Edinburgh: Young J. Pentland. 1906 and 1907. Price 21*s.* net.

THE student must have a good deal of difficulty in distinguishing between the many manuals of surgery which compete for his notice, but he cannot go far wrong in choosing this excellent text-book. It is always difficult to know how much to put into a book intended for students; on the one hand, the author has to avoid overburdening the student's mind with an excess of facts and particulars, and on the other it is essential that everything should be included that may be reasonably required at the examination. We do not know a more trustworthy work than this. We are inclined to think that it would be better to issue the work in one volume, the page being made larger, for there is certainly on the part of students a preference for a work in one volume. We hope the authors will resist strenuously any inclination to increase unduly the amount of material in the work; we notice that the present issue has 100 pages more than the first, and all books have a natural tendency to grow. We are glad to see that the book has reached a second edition in which it has been brought up to date. We notice a misprint "praritis" for "praritus": we mention it because in some works, especially in America, it appears to be regarded as the correct spelling.

LIBRARY TABLE.

Primary Nursing Technique for First-year Pupil Nurses. By ISABEL MCISAAC, formerly superintendent of the Illinois Training School for Nurses, Associate Director of the *American Journal of Nursing*, &c. New York: The Macmillan Company. 1907. Pp. 197. Price 3*s.* net.—It is a truism that the only way to learn the art of healing is by observation of the patient at the bedside and it is no less certain that the art of nursing can only be acquired in a practical manner. But text-books, intelligently used, may be of as much help to the nurse as to the student of medicine, and the book before us is one that the first-year probationer will find of very valuable assistance in her training. It is written clearly and concisely and is not

THE LANCET.

LONDON: SATURDAY, FEBRUARY 8, 1908.

The Assassinations in Portugal.

For the third time within ten years the ruling house of a European country has had one of its most prominent members struck dead by the weapon of an assassin. On Sept. 10th, 1898, the Empress of Austria was done to death by Luccheni. On July 29th, 1900, King Humbert of Italy, whose life had been twice previously attempted, was shot at Monza by Bresci. And on Feb. 1st, 1908, King Carlos of Portugal and his son the Crown Prince were shot dead in their carriage by sundry assassins armed with repeating carbines. Queen Amélie and the Infante Manuel, now the King, escaped as by a miracle, for the assassination had been most carefully planned, for there are said to have been some 30 men told off to carry out the plot, which apparently included the killing of the whole Royal Family. In the presence of such a tragedy our modern civilisation stands dumb; we can but offer our sympathy to the widowed Queen deprived at one blow of her husband and her son.

All modern political assassinations have one marked feature in common and that is their absolute uselessness from the point of view of the fanatics who plan them. From the murder of President Lincoln in 1865 down to that of King Humbert not one assassination has brought about any change of constitution, and in some instances, instead of obtaining more liberty, the killing of the ruler has very naturally been the means of increasing repressive measures. No common reason has ever governed these crimes. In many instances the slain ruler was the head of a republic, for instance, Lincoln, Garfield, Carnot, and McKinley, while the Empress of Austria was not a ruling monarch. Alexander II., the last Emperor of Russia who met his death by assassination, had already freed the serfs and was on the eve of granting a constitution when he was killed. Humbert of Italy was unsparing in his care for his people and his devotion during the appalling calamities which afflicted his country, such as the earthquakes in Ischia in 1881 and in 1883 and the cholera at Naples in 1884, was as humble and self-sacrificing as any man's action could be. Carlos of Portugal was a popular and (in the words of our Prime Minister) "a manly, friendly, kindly king." His desire to promote the well-being of his subjects was genuine. Our readers, for example, will remember his eloquent speech at the opening of the International Congress of Medicine at Lisbon in 1906, in which he referred to the necessity for organised work against the ravages of tuberculosis, while testifying to the personal efforts in this direction made by Queen Amélie.[1] The Crown Prince was a popular and blameless youth. The brutal murder of father and son leaves the dynasty at least as firmly seated on the throne as it was before, though the principle of the dictatorship has been abolished. The latest crime proves once again that nothing is sacred to the modern political assassin. He has but one ideal—namely, a blind hatred of any authority. It is enough that a man should be the titular head of a State and at once he is a mark for the knife, the bullet, or the bomb. The political assassin—that is to say, the actual murderer—is, as a rule, a man of no education, or of worse than no education, some one who has imbibed washy theories about liberty, which word he translates into license. Behind the actual murderer we find usually a group of badly educated unemployed professional men who disdain a life of honest work and who knowingly or unknowingly are always ready to hound on the worse educated lower classes to deeds of blood which they themselves are too cowardly to perform.

As to the political events which have led up to the present crime it is not our province to discuss them. Given a Latin population, a widespread ignorance, a people quick to feel and quick to resent, and one conscious, or partially so, of the time when Portugal was paramount throughout nearly the whole known world, political unrest is to be looked for; the appointment of a dictator seems to have been the spark which set fire to the powder. To the young king who with his widowed mother will, it seems, have to share between them for some years at least a burden the weight of which might well overcome an experienced ruler the sympathies of all in this country will go out. Portugal has been leagued in friendly relations with the inhabitants of these islands since 1145, and there was a formal alliance between the two Crowns in the reign of Henry V. In many ways our peoples are alike. Both Portugal and these islands have bred hardy warriors, explorers, and navigators. From both lands great geographical discoveries have resulted, while the sovereigns of either country have only recently been received in the other's land with every mark of affection and respect. In no foreign country more than in the United Kingdom will sorrow for the living, regret for the dead, and horror at the crime be more widely spread.

Quack Medicines in Japan.

"Dans l'adversité de nos meilleurs amis," wrote La Rochefoucauld, "nous trouvons toujours quelque chose qui ne nous déplait pas," and we are indebted to the number for last August of the *Journal of the Asiatic Society of Japan* for the information that our very good friends in the island empire of the East are sufferers to almost as great an extent as ourselves from the plague of quack medicines and quack advertisers. There is at least this much which may not be displeasing to us in the intelligence that, assuming, as we may surely do, the supply of quack medicines to be a response to some demand deeply seated in human nature, we are very likely to receive from Japan before long some practical suggestions concerning the way in which this demand may be satisfied with the smallest amount of injury to the community. Our allies are usually both scientific and thorough-going in any reforms which they undertake; and if it were ever shown that quacks and quack medicines were to them the public injury and nuisance which they are to ourselves, we have little doubt that remedial measures from which we might take a lesson would be adopted with regard to them.

---

[1] In our issue of April 28th, 1906, we published an interesting picture of the King and Queen of Portugal presiding at the opening ceremony of the International Congress.

afford important evidence that these hygienic matters are receiving greater and more intelligent attention from practical engineers.

Man.—In the January number of *Man* Dr. W. L. H. Duckworth describes a human cranium obtained from a stone cist in the Isle of Man. Its measurements in millimetres were as follows: Maximum length, 180; maximum breadth, 146; and horizontal circumference, 527. The cephalic index was 81·1. It was therefore brachycephalic and probably belonged to a young adult. A noteworthy feature was the persistance of a suture (comparable to a prolonged sagittal suture) between the two halves of the frontal bone.

The Phonographic Record.—With the January number our small contemporary begins its fourteenth annual volume. In his account of the Medical School of Montpellier in the thirteenth century Dr. O. C. Gruner presents many curious facts. At its prime the number of students was not less than 1000. They had the power of regulating the manner of teaching and even the subjects to be taught, and they could suspend altogether an unsatisfactory teacher. Perhaps an explanation of this is to be found in the fact that any unqualified person, as we should say, was at first able to be a teacher; not until 1272 was the possession of a diploma necessary. In an account of the Murmurs of Mitral Constriction Sir William Gowers mentions two phases or stages rarely observed. The first is at the beginning of the diastolic murmur, when a distinct interval intervenes between the end of this and the beginning of the presystolic murmur, because the narrowing of the orifice is only enough to cause the sound at the commencement of the diastolic flow. It is more often noted in an irregular heart, when the diastole is occasionally prolonged. The other stage is terminal; the presystolic murmur ceases and only the diastolic persists. He observed a case in which the cause of this was found to be the formation of a layer of clot over the whole inner surface of the auricle, making its contraction impossible. Dr. R. Hingston Fox contributes a sketch of "Hæmatogenous" Albuminuria, often called "functional," a subject on which it will be long before the last word is said.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

ALEXINE.

(J. CHATELAIN, 15, RUE DE PARIS, PUTEAUX. AGENTS: T. CHRISTY AND CO., OLD SWAN-LANE, LONDON, E.C.)

WE have submitted this preparation to analysis and the results confirm the statement that it contains free phosphoric acid with iron and manganese. The preparation occurs in granular form but is distinctly hygroscopic. It is by no means unpleasant to take and for the most part is soluble in water. The acid phosphates of manganese and iron are regarded as presenting both these metals in an assimilable form. The preparation appears to supply an effective tonic and has been used in nervous diseases, in dyspepsia, in anæmia, and in pulmonary tuberculosis.

IRISH WHISKY.

(DUNVILLE AND CO., LIMITED, BELFAST.)

Two specimens of Irish whisky were submitted to us, one distinguished by the letters V.R. and the other by the title of "Special Liqueur." Analysis readily discriminated the two, the former being a blend of pot-still and patent-still spirit and the latter a pure pot-still spirit. The V.R. whisky, for example, showed a relatively small proportion of secondary products, the ethers amounting to 26, the higher alcohols to 107, and the furfural to 0·3 parts per 100,000 parts of absolute alcohol present. On the other hand, the specimen marked "Special Liqueur" yielded on analysis 1 part of furfural, 65 parts of ethers, and 400 parts of higher alcohols in 100,000 parts of absolute alcohol present. It will be noticed that the amount of furfural is relatively low having regard to the fact that the spirit is distilled in a pot still. Doubtless this is due to careful selection of a particular "running" from the still. Since furfural is held to be a poisonous constituent of whisky this fact may be regarded as satisfactory from a dietetic point of view. Both spirits evidently belong to the class of whisky described as "thoroughly matured." Those who know the peculiar characteristics of genuine Irish whisky will appreciate the flavour in particular of the "Special Liqueur." The specimens were entirely free from acrid flavour and were peculiarly smooth to the palate. They were, moreover, free from excess of extractive matters and exhibited practically no acidity.

FORMAMINT.

(A. WULFING AND CO., 83, UPPER THAMES-STREET, LONDON, E.C.)

Formamint is described as a chemical combination of formaldehyde and milk sugar. Apparently it is a true compound of the two substances, the milk sugar neutralising the irritating effect of the formaldehyde. The result is that the compound may be formed into a lozenge for the treatment of infective throat conditions. When the tablet is dissolved in the mouth the taste of formaldehyde is distinctly observed, though it is not unpleasant. The act of dissolving in the saliva sets free the aldehyde. Under these conditions the bactericidal action of the aldehyde is powerful and immediate. Several clinical notes have been published recording the value of the Formamint lozenge in tonsillitis, diphtheria, thrush, and so forth. We had no difficulty in recognising the presence of formaldehyde, lactose, and some starch.

TABLOID QUININE COMPOUND.

(MESSRS. BURROUGHS, WELLCOME, AND CO., SNOW-HILL BUILDINGS, LONDON, E.C.)

The formula of this compound will explain the purpose for which it has been designed. Each tabloid contains cinchona alkaloids, 1 grain; acetanilide, $\frac{1}{12}$th grain; camphor monobromate, $\frac{1}{3}$th grain; powdered ipecacuanha, $\frac{1}{8}$th grain; and extract of cascara sagrada, $1\frac{1}{4}$ grains. It is suggested that one tabloid may be taken every hour in the early stages of catarrh of the kind to which many persons are prone during a cold and changeable season.

VARIOUS FOOD PREPARATIONS.

(EUSTACE MILES, 40, 41, AND 42, CHANDOS-STREET, CHARING CROSS, LONDON, W.C.)

These foods in general show, according to analysis, a high nutritive value in regard to all classes of material which minister to the needs of the body. The "Proteid Food," for example, contained as much as 32 per cent. of proteins which are more or less in a soluble state, and the mineral salts amounted to 7·10 per cent. Its addition to other foods is, of course, calculated to raise their nutritive value. The food for infants contains a well-balanced proportion of proteins, fats, carbohydrates, and mineral matter. It is a particularly satisfactory fact that this food showed no deficiency in regard to fat, the amount being 21 per cent. The proteins amounted to 22·75 per cent. and the mineral matter to 4 50 per cent. We have also examined cocoa, biscuits, and soup tablets, which all evidenced a rich proportion of nourishing constituents.

"DRY SACK."

(WILLIAMS AND HUMBERT, 28, MINCING-LANE, LONDON, E.C.)

This is a very fine wine, representing the best that can be produced in the Jerez district. It is said to have been fully matured in wood, which we can well believe from the excellent flavour of the wine. The results of analysis accord with those commonly obtained with a fine old matured colonies supplied with immigrants—is practically in a subordinate position, with a result that considerations as regards health are relegated to a second place in the councils of the nation. So much is clear, but the immediate creation of a Ministry of Public Health does not follow. To detach a small portion of the administrative routine of the Local Government Board and to accord to it the title of a "Ministry of Health" would be to create an additional Government department with no status, no direct voice in the Cabinet, and no power with the Treasury. Such a step would seem to us to put back the public health progress of this country by a quarter of a century, much as we sympathise with many of the arguments of those who desire such an innovation.

The remedy for the present admittedly unsatisfactory state of affairs is, we think, not the division but the aggrandisement of the Local Government Board, the expansion taking the form of creating a Secretary of State for Public Health, upon which would follow the development of that medical department the classical researches and reports of which have carried its fame far beyond these isles but which has not received from the State the encouragement which it unquestionably deserves. A Government department occupying but a very secondary rank in the Cabinet always runs the risk, as events have over and over again shown, of losing by promotion the services of a valuable Minister. We have recently heard rumours of changes which would transfer Mr. BURNS to a higher office and which would fill the Local Government Board with an untried hand who might occupy the next few years in learning the work, only to be removed at the end of that time by promotion. In the name of public health we protest against a condition of things which makes this waste of force possible at a time when the President of the Local Government Board is about to introduce into the legislature measures of the greatest importance as regards health. The subject will be shortly discussed in Parliament by Mr. CHAPLIN, who is to move an amendment to Sir WILLIAM HOLLAND'S amendment to the address, and this, if carried, will express the opinion of the House of Commons that the Local Government Board shall be placed on a par with the office of a Secretary of State. We sincerely hope that this movement will be supported by all municipal and public bodies throughout the country and that powerful deputations will wait upon the PRIME MINISTER urging the emancipation of public health from the disqualification and anachronism of being associated with a secondary position in the State.

HARVEIAN SOCIETY.—At the annual general meeting held at the society's rooms the following officers were elected for the ensuing year. President: Mr. D'Arcy Power. Vice-Presidents: Dr. G. A. Sutherland, Dr. C. Buttar, Dr. H. J. Macevoy, and Dr. W. H. Blenkinsop. Treasurer: Mr. Francis Jaffrey. Honorary secretaries: Mr. T. Crisp English and Dr. W. H. Willcox. A good programme of work has been arranged. The Harveian lecture will be delivered by Sir Almroth Wright upon Some Points in Connexion with Therapeutic Immunisation, and among other papers promised may be mentioned one by Dr. Samuel West on the Treatment of Pneumonia, to be followed by a discussion.

Annotations.

"Ne quid nimis."

TUCKER v. WAKLEY AND ANOTHER: THE SYMPATHY OF THE MEDICAL PROFESSION.

WE are truly grateful to the many members of the medical profession who have written to us in terms of sympathy in regard to the issue of the recent libel action. It is plain to us that the medical profession has perceived fully that the course which we took was dictated to us by every reason there is for our existence and by every tradition of our career. At a meeting of the Council of the British Medical Association held on Jan. 29th, on reference being made to the case, the Chairman of Council, Mr. Edmund Owen, was requested to convey to us the following gratifying resolution which we learn from Mr. Owen was passed by the Council unanimously:—

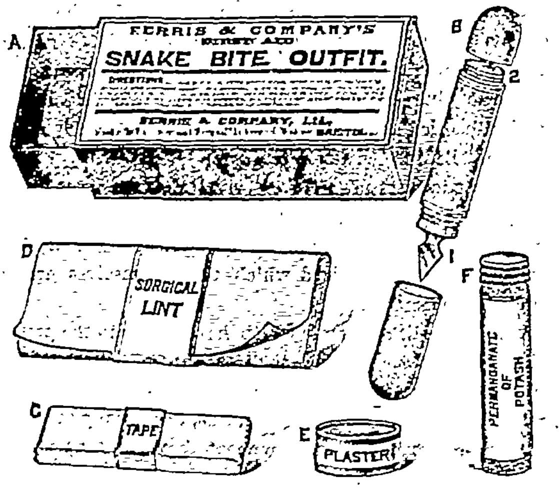
RESOLUTION.

That the Council, recognising the injury done to the public by the uncontrolled sale of secret remedies, desires to place on record its entire sympathy with the proprietors of THE LANCET on the result of the recent action, Tucker v. Wakley and Another.

We desire to thank the Council of the British Medical Association, and the great constituency which they rule, for their valuable support.

DANGER IN GAMES FOR BOYS.

AN action was tried recently in the High Court in which a schoolmaster was the defendant and the plaintiff a schoolboy whose leg had been broken while playing a game under the supervision of the master. It was contended that the defendant was negligent in permitting a dangerous game, consisting in races between boys, each of whom carried another boy on his back, across an asphalted playground. The plaintiff was said to have carried a boy heavier than himself and to have slipped at a gully and fallen, fracturing his thigh. Medical evidence to the effect that the game was dangerous and also that it was not calculated to lead to any desirable physical improvement in the player and so fulfilled no useful object was given by Dr. J. N. McTurk of the Hospital for Sick Children, Great Ormond-street, but Mr. Justice Lawrance appears to have taken the view that to give effect to such an opinion would unduly restrict boys' games, and comparisons were made by him between the accident which occurred and the possible injuries which may be inflicted at cricket by the ball striking a boy's head. The jury eventually found a verdict for the defendant with which none need find fault if allowance is made for the position of a master in an elementary school, who no doubt did his best to organise the amusements of those entrusted to his care in circumstances which render healthy and recreative exercise in which all can join a difficult thing to provide. At the same time, the opinion that the game played is not a desirable one is surely a correct one. It has attractions for boys because it requires no apparatus beyond what they themselves can supply and it lends itself to friendly competitions in strength and endurance. It is, however, very easy for the carrying boy to fall while overweighted by his fellow borne on his back, and when he falls he does so not only with the other on top of him but with no power to save or to protect himself, as his hands are occupied in keeping his rider in his place and he has no time to disengage them. If the plaintiff had come down on the asphalt on his face he would probably have suffered considerable disfigurement, and though he or any of his fellows might have fallen without actually which is hollowed out so as to contain a supply of the permanganate. On the infliction of a bite free incisions are made in the part with the lancet and crystals of the permanganate are rubbed into them. The accompanying illustration shows at B an instrument of this kind, manufactured by Messrs. Ferris & Company, Limited, of Bristol, who have added some useful adjuncts, the whole of which are contained in a cardboard box of a size convenient for the pocket. B is a double-ended case of polished hardwood, having at one end a short spear-pointed lancet protected by a cover and at the other end a receptacle for the crystals. When closed it is three and a half inches long and half an inch in diameter; it may be carried alone if desired but the outfit as shown includes a small stock of dressing materials and an extra supply of crystals in a glass tube marked F. The price is 3*s.* 6*d.* The permanganate treatment of snake-bite has received official approval in Burma and in THE LANCET of Jan. 25th one of our India correspondents gave an abstract of recent regulations on the subject.



ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A COMITIA was held on Jan. 30th, Sir R. DOUGLAS POWELL, Bart., K.C.V.O., the President, being in the chair.

The PRESIDENT announced the following appointments: Dr. L. G. Guthrie to be the FitzPatrick lecturer for 1908, Dr. J. A. Ormerod to be the Harveian orator for 1908, Dr. W. Pasteur to be the Bradshaw lecturer for 1908, and Dr. R. T. Hewlett to be the Milroy lecturer for 1909.

The following gentlemen having passed the required examinations were admitted as Members of the College: Jehangir Cawasjee Balsara, L.R.C.P.; Hector Charles Cameron, M.A., M.B. Cantab., L.R.C.P.; Carey Franklin Coombs, M.D. Lond.; John Gallie Fraser, M.B. Edin.; Charles Edward Iredell, M.D. Lond., L.R.C.P.; John Owen, M.D. Lond.; Herbert Chavasse Squire, M.A., M.B. Oxon., L.R.C.P.; Henry Letheby Tidy, M.B. Oxon.; Godfrey de Bec Turtle, M.D. Durh., L.R.C.P.; Rupert Waterhouse, M.D. Lond., L.R.C.P.; and John William Watson, L.R.C.P.

Licences were granted to 63 gentlemen who had passed the required examinations.

Diplomas in Public Health were granted jointly with the Royal College of Surgeons of England to the following gentlemen: Robert Cecil Turle Evans, L.S.A.; Ernest Edward Scott Joseph Galbraith, L.R.C.P. & S. Edin., L.F.P. & S. Glasg.; William Henry Hillyer, L.R.C.P. Lond., M.R.C.S. Eng., M.D. Durh.; Wharton Henry Lamplough, L.R.C.P. Lond., M.R.C.S. Eng., M.D., B.S. Durh.; Arthur Riencsett Litteljohn, L.R.C.P. Lond., M.R.C.S. Eng.; James Mair, M.B., C.M. Glasg.; Fairlee Russell Ozzard (Major I.M.S.), L.R.C.P. Lond., M.R.C.S. Eng.; George Elliott Frank Stammers (Captain R.A.M.C.), L.R.C.P. Lond., M.R.C.S. Eng.; James Batson Stephens, L.R.C.P. Lond., M.R.C.S. Eng., M.B., B.S. Lond.; and John Tate, L.R.C.P. Lond., M.R.C.S. Eng.

The following communications were received:—1. From Mr. Charles Coates of Bath (to the President) presenting the College with the sum of £1000 to be used, invested, or disposed of as the President might deem most desirable. The thanks of the College were ordered to be given to Mr. Coates for his generous gift. 2. From the Secretary of the Royal College of Surgeons reporting proceedings of the Council on Jan. 16th, 1908. 3. From the council of the Geological Society conveying the thanks of the society to the College for its assistance in the recent celebration of the centenary of the society. 4. From the General Medical Council requesting recommendations from the College in reference to the new edition of the British Pharmacopœia. A committee was appointed to consider any alterations or additions which might be deemed advisable. The committee consisted of Dr. F. Taylor, Dr. J. Mitchell Bruce, Dr. N. I. C. Tirard, Dr. W. Hale White, Dr. H. A. Caley, and Dr. J. Calvert. 5. From Dr. Norman Moore, presenting a report on the November meeting of the General Medical Council. The report was received and adopted.

Dr. G. E. Herman, Dr. D. A. Finlay, Dr. N. I. C. Tirard, and Dr. W. P. Herringham were elected councillors.

Dr. T. D. Acland was elected an examiner in medicine in place of Dr. H. M. Murray, deceased.

Dr. F. H. Champneys was re-elected a representative of the College on the Central Midwives Board.

Sir W. S. CHURCH proposed, and Dr. G. A. HERON seconded, that a small standing committee should be elected the business of which would be to keep the College informed of the arrangements and methods of teaching elementary hygiene in training colleges and schools, of the working of Section 13 of the Education Act (medical inspection of the public elementary schools), of the position of the medical officers employed under it, and of any alterations which might be proposed by the Government or others in the education or inspection of children or in the administration of the Act. The motion was adopted. The nomination of the committee was postponed.

The quarterly report of the College finance committee was received and adopted.

After some further formal business the PRESIDENT dissolved the Comitia.

Looking Back.

FROM

THE LANCET, *SATURDAY*, Feb. 6th, 1830.

MONSIEUR CHABERT.[1]

THIS person having advertised that he would REPEAT the WHOLE of his "extraordinary performances" on Thursday, the Editor thought it his duty to attend, in order to administer a dose of prussic acid to him. When challenged, however, Monsieur Chabert, in the most peremptory manner, refused to take the poison. Considerable uproar ensued, and Monsieur Chabert, after much prevarication, promised that the money should be returned, and he left the room to give the check-tickets, as he said, to the cashier. He was immediately followed by a large portion of the company—pressed upon rather severely by several gentlemen down the staircase, and at length was fairly got out upon the pavement in Regent Street, where, finding one of the gates of the area open, he bolted from his pursuers down the steps, ran up the entire length of the area towards Oxford Street, and *ultimately concealed himself in a coal-cellar. Attention was* then directed to the proprietor of the rooms, Mr. Welch, who, after much clamour on the part of the assembly, directed that the money should be returned, or tickets be given to the claimants, securing payment on another day. The exhibition-room was crowded to excess, and it was stated, at the doors, that upwards of five hundred persons left who were unable to obtain admission.

As we are just going to press with this part of our Journal, we have neither time nor space to say more on the subject of this disgraceful humbug; but in our next Number we will endeavour to publish a full and accurate report of the proceedings. It is, however, more than probable, that public curiosity will be gratified by an account of them in the daily journals.

---

[1] Vide "Looking Back" in THE LANCET of Jan. 18th, p. 178, and Feb. 1st, 1908, 323.

or concert-house within reasonable distance? Moreover, to alter still further the trend of public opinion the universities should themselves encourage research into the many problems involved in the question of alcohol and publish the results with their weight of authority. By the establishment of a sensible and firm public opinion on the matter nearly all the difficulties of politicians and social reformers would disappear. While we are in agreement with Mr. Eccles as to the damage wrought by over-indulgence in alcoholic drinks and with many of his suggestions for dealing with the matter, yet we are not by any means certain that legislation will be of any avail. Education, the provision of places other than public-houses for amusement and light refreshments, combined with honest light beer or some similar drink, will do more to solve the problem than any amount of repression. Within the last 20 years the consumption of alcoholic drinks has diminished enormously and that not owing to legislation but to the development of common sense and the provision of rational amusement for those whose lives are cast among grey and dismal surroundings.

THE CHARRED CEILING.

A SIMPLE test which everyone can try for the presence of free sulphuric acid in a liquid consists in streaking the liquid upon a piece of white paper as with a quill pen and drying the paper before the fire. The track of the sulphuric acid, if any is present, is marked out by a black line appearing as soon as the paper is dry and warm. In short, the acid in this procedure is concentrated until it becomes strong enough to char the paper. The test is quite delicate and is practically demonstrated in the rooms of a house lighted by means of coal gas. Sooner or later the ceiling of a room in which gas-lights are burning is blackened, and if chimneys over the burners are used the blackening is more or less localised in a ring immediately over the burner. The common acceptance of this is that soot is deposited, whereas the discolouration may not be due to soot at all. We had occasion recently to examine the circular patches of discolouration which appeared in just those places on a papered ceiling which were immediately above a gas burner. The apparently charred pieces of paper were very acid and sour to the taste and on soaking them in distilled water a weak solution of sulphuric acid was obtained. Further examination showed that the amount of sulphuric acid in the paper was equivalent to as much as 16 grains of pure acid to the square foot. The charred ceiling, therefore, is the result of the action of sulphuric acid derived from the combustion of the sulphur compounds contained in the gas upon the organic substances in the ceiling or in the paper (if it happens to be papered). It is fairly reasonable to suppose that the action of this sulphuric acid is not limited to one part of the ceiling but in course of time becomes general. The use of a chimney on the gas burner concentrates the mischief on the ceiling and hence the more or less rapid appearance of black circular patches immediately over the burners. In the case of a papered ceiling the paper is sooner or later destroyed, chars, crumbles, and peels off. When there is no chimney the products of combustion are to an extent distributed and then the charring is spread over a greater surface, the ceiling getting seared uniformly throughout, but not so intensely, of course, as when the effects of the gases are localised. This is why the inverted incandescent gas burner appears to blacken the ceilings to a less degree than the upright burner provided with a chimney. The products of combustion in the former case are distributed, while in the latter they are concentrated and directed to a comparatively small part of the ceiling. The worst feature from a health point of view of gas lighting is undoubtedly this production of sulphurous and sulphuric acids, for in comparison with these the other products of combustion—namely, the moisture and carbonic acid gas which are both normal products of human exhalation—may for all practical purposes be neglected unless, of course, no precautions are taken in regard to their removal by ventilation. It is to be regretted, therefore, that the hitherto strict requirements concerning the permissible amount of sulphur components in coal gas are in many cases relaxed. We are quite aware that the complete removal of sulphur from coal gas is a very costly business in its manufacture, but if an economical method of freeing coal gas entirely from sulphur could be devised and put into practice the chief argument which hygienic considerations raise against the use of coal gas for lighting and even heating purposes in some cases would have to be dismissed. As it is, the obvious drawback to coal gas containing sulphur compounds is that the products of its combustion are calculated to do damage to the appurtenances of the dwelling room and add to the atmosphere a constituent or constituents which in the interests of health should not be there.

THE HISTORY OF KEFIR AND ITS MODE OF PREPARATION.

KEFIR has been esteemed as a beverage from time immemorial by the inhabitants of the northern part of the Caucasian mountains. Its history and mode of preparation are well described by Dr. J. V. S. Stanislaus in the January number of the *American Journal of Pharmacy*. Kefir is not an imitation of koumis which is made by the Tartars from mare's milk. It is prepared from cow's milk, by the action of a ferment called "kefir grains." The origin of kefir grains is not definitely known but the tribes of the Caucasus consider them to have a sacred origin. There is an Oriental legend that the first Mohamed conferred this blessing upon his chosen people. Hence the grains are known as the "millet seeds of the Prophet." In Europe they are variously known as "kefir champignons" and "kefir mushrooms." Professor Podwysocki of Riga has explained their origin in the following way. Certain tribes, migrating into the mountains, were obliged to raise more cattle than horses, with the result that there was a shortage of mare's milk. They therefore added the koumis ferment to a mixture of cow's and mare's milk and in the course of time the ferment acquired a different form and composition, constituting what are known as kefir grains. Until recently the tribes dared not offer the grains for sale or even as a gift, because there existed a strong belief that by parting with some of them the remainder would lose their fetichistic power to ferment. At the present time they may be purchased without much difficulty. When kefir grains are added to cow's milk alcoholic and lactic fermentations occur and the albuminous bodies are peptonised. Kefir, when 24 hours old, contains 4·15 per cent. of albuminous substances, as compared with 4·08 per cent. in cow's milk. It contains, in addition, 0·49 per cent. of alcohol, 0·52 per cent. of lactic acid, and 2·05 per cent. of lactose, as compared with 4·92 per cent. in cow's milk. It contains no fat, is whitish in colour, and pleasant to taste. In preparing kefir healthy grains may be recognised by their irregular form and size, their hardness, and yellow to brick-red colour. The first step consists in making the "starter." This is done by macerating the grains in warm water for 24 hours, changing the water at least four times. Two tablespoonfuls of the soaked grains are then strained from the water and added to about 350 cubic centimetres of fresh milk. The vessel is covered with muslin and kept at a temperature of 15° to 18° C. until the grains begin to float upon the surface of the liquid, care being taken to stir the mixture occasionally during the first few hours. The grains can be used again several times. The strained liquid constitutes

In the meanwhile, it is interesting to hear that the public places of Japan are being systematically invaded by the unsightly advertisements which were first introduced in the United States and have spread with lamentable rapidity amongst ourselves; because an outrage to the public sense of beauty and fitness is perhaps more likely to bring about reforms than any probable recognition of the mischiefs done by quacks and their nostrums to the public health. There is, at least, one point in which the Japanese administration contrasts favourably with our own, and it is that although the makers and sellers of quack medicines are taxed, as prostitution and other noxious trades are taxed in many countries, they are not, as with us, taxed in a manner which appears to imply governmental sanction or approval. There is no such a thing as a "government stamp" without which the preparation is not "genuine," and which is accepted by the ignorant as implying that if not Sir HENRY CAMPBELL-BANNERMAN or Mr. BALFOUR at least the Home Secretary is responsible for the "genuineness" in question, and is an accessory to the statements put forth by bold advertisement. Whenever Japanese statesmen realise that the national expenditure on quack medicines is, to say the very least, an entirely wasteful one, that reliance upon these preparations constantly serves to postpone the proper treatment of originally curable maladies until the period of curability has passed away, and that a very large proportion of the so-called remedies are merely combinations of "nips" of alcohol with soothing doses of narcotics, calculated to bring these things into homes to which they would not otherwise have obtained access, we shall no doubt see the prompt adoption of remedial measures against the insidious sale of very dangerous poisons. If that time should come we may at least hope that some among our own politicians will be able to discover a chance of popularity in following the Japanese example.

It appears from the articles by Mr. ROYDS and Mr. CLEMENT in the journal to which we have referred, that while the sale of quack medicines in Japan is effected by an organisation of pedlars rather than in shops, the representations put forth by the makers do not differ in any material degree from those with which we are only too familiar. Among the things sold are "brain-healing pills," "poison-expelling pills," "spirit-cheering pills," "heal-everything powders," "one-dose-healing powders," "life-supporting powders," and "touch-the-spot pastiles." Our "pills worth a guinea a box" are fairly surpassed by the "thousand dollar pills" of Japan, pills the selling price of which is, we believe, expressed in fractions of a penny. In other respects, too, there are many points of resemblance; and the chief differences between the English *quack* and his Japanese brother appear to depend on the fact that the popular superstitions to which both appeal are somewhat different in the two countries. But for this the methods and the pretensions are the same in both, and scarcely depart from those which prevailed among ourselves 150 years ago and were described by GOLDSMITH in his "Letters from a Citizen of the World." Then, as now, our quacks received their knowledge of medicine by immediate inspiration from heaven and often spent a great part of their lives in unconsciousness of any latent excellence until a bankruptcy or a residence in jail called their miraculous powers into exertion. Then, as now, notwithstanding the existence of infallible remedies for every disease which it is possible to mention, there were many who thought it proper to be sick and even sometimes to die. "Yes, by the head of CONFUCIUS, they die, though they might have purchased the health-restoring specific for half-a-crown at every corner."

◆

A Ministry of Public Health: Is it Practicable?

THE people of this country are at last awakening to the fact that if the nation is to hold its own in the constant struggle for survival which is part and parcel of nature's method of improving the world's stock, the physical fitness of the individual must receive more attention than heretofore. It is true that the death-rate is steadily declining and that the toll levied by that disease which has been erroneously termed the "white man's plague" is slowly but surely becoming less, but it is equally true that the birth-rate has reached a dangerously low figure, that our infantile mortality is still appalling, and that the aggregation of the bulk of our population into towns may be, and not improbably is, interfering steadily with the stamina and physique of the people. The appeal to a declining death-rate is liable to delude us, seeing that it is possible by shielding weakly persons against all those conditions which are likely to determine life by accidents or to cause a fatal issue through disease to rear a race which under untoward conditions, such as war or famine, would melt away into death or incapacity with amazing celerity. We fully admit that much of this may be mere speculation; but the fear that the speculation may be true and that we may ere many years be past have, like France, a birth-rate only equal to our death-rate is bringing home to all seriously minded persons the need for every effort to be made to improve the public health. Discontent with existing conditions of affairs is finding expression in a demand that the central health department, the Local Government Board, shall be given a better position amongst Government departments and in the Cabinet than it at present possesses, and everyone who speaks upon the subject is expected either in his prologue or his peroration to call for the creation of a "Ministry of Health."

We are afraid that most of those who make this demand have but little knowledge of what they really mean in a creative sense; but it is assumed that they are expressing dissatisfaction at the circumstance that while foreign, colonial, Indian, and military affairs are presided over by a Secretary of State, the health of the nation is consigned to a Minister who has multifarious and heterogeneous duties and who, although in the Cabinet, occupies an altogether inferior position, and who receives as an emolument a sum less than half that accorded to a Secretary of State. In other words, Mr. BURNS—who is, or should be, responsible for the physique of those who man our ships and form our territorial forces, and who should be doing *something* to insure that there may still be a margin of population which may help to keep out

Brussels, 30·5°, being exceptionally low. Both at home and abroad the period was dry. On the French Riviera, as represented by Nice, there was no measurable quantity of rain, while at almost all the other foreign resorts, as well as those on our own south coast, the number of days with rain was very small. As a rule, the month was very sunny in Italy, the Riviera, and the Mediterranean region generally, and there was also much more sunshine than usual on the south and south-west coasts of this country. The figures from the foreign resorts were not available and those for the home resorts are not given in the above table, but the number of hours registered at many places in the south and south-west of England was between 80 and about 100. At some spots the figure was about twice as high as usual. Over the more inland parts of the country the sun was frequently obscured by fog and mist. In London (Westminster) there were only 22 hours of sunshine, while at Manchester there were no more than about ten hours. It would not be fair to compare the duration of sunshine in London with that at places on the south coast, but as the sun shone brightly for 64 hours at Bath, an inland spot practically in the same latitude as the metropolis, it may be assumed that the smoke and dust robbed the more central parts of London of at least 40 hours of health-giving sunshine. At Manchester there were 25 sunless days, at Westminster 14, and at Nottingham, where the aggregate number of hours of sunshine was 38, there were also 14 sunless days.

ALCOHOL IN THE TREATMENT OF PNEUMONIA AND ENTERIC FEVER.

THE International Union of Medical Abstainers, founded at Stockholm in 1907, has resolved as part of its operations to attempt the solution of the question as to the value of alcohol in the treatment of lobar pneumonia and enteric fever. A statistical inquiry is to be instituted and "all hospital and infirmary physicians, medical superintendents, or registrars are earnestly requested to assist in this work, both in the interests of medical science and of the sick." Whilst agreeing that trustworthy information on this point is desirable we cannot give unqualified approval to the methods which it is proposed to adopt. The proposed lines of the inquiry are as follows. There are two distinct plans which may be adopted by those wishing to help in the accumulation of statistics: "Plan A. 1. Every participator declares himself prepared to treat all cases of lobar pneumonia and enteric fever over 15 years of age which he may have to treat in hospital or otherwise between January 1st and December 31st, 1908, alternately—i.e., the first with, the second without, alcohol, and so on. 2. The administration of alcohol is to be as usually given by the reporter both as to form, quantity, and duration. It is desirable that a mixture of alcohol and water should be used of definite strength as the commercial wines and spirits vary considerably. 3. The other treatment will be on the usual lines according to circumstances. 4. Departure from the treatment in turn is especially deprecated, but if for some reason (such as intolerance of alcohol) it occurs it should be noted on the form with the reason for such occurrence. Plan B. 5. If the alternate treatment of cases with and without alcohol is objected to it is hoped that the alternative proposal will be adopted—viz., a simple return of the treatment as regards alcohol and the result on the same form. 6. Every case is to be reported on a form which will be supplied on request. These forms should be returned to Dr. J. J. Ridge, Carlton House, Enfield, not later than January, 1909." We imagine that few physicians, who have been accustomed to give alcohol in cases of lobar pneumonia and enteric fever, would consent to have their treatment dictated in this manner, so that their patients should be treated alternately, with or without alcohol, although they might be perfectly willing to give the statistics of the results of cases that have come under their care. Plan B commends itself to us more favourably than Plan A, but whether any trustworthy conclusions will be arrived at from this inquiry remains to be seen. The personal equation in such an investigation is difficult to eliminate but nevertheless we have no wish to discourage any attempt to arrive at the value of alcohol as a drug and we shall watch the result of this endeavour with interest.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE lectures of the Royal College of Physicians of London for the present year will be delivered at the College, Pall-mall East, on the following Tuesdays and Thursdays at 5 o'clock: The Milroy lectures on Melitensis Septicæmia (Malta or Mediterranean Fever) will be delivered by Dr. J. W. H. Eyre on March 5th, 10th, and 12th; the Goulstonian lectures on the Influence of Pregnancy on certain Medical Diseases, and the Influence of Certain Medical Diseases on Pregnancy, will be delivered by Dr. Herbert French on March 17th, 19th, and 24th; the Lumleian lectures on Points of Practice in Maladies of the Heart will be delivered by Sir James Sawyer on March 26th and 31st and April 2nd; and the Oliver-Sharpey lectures on the Present Position of our Knowledge regarding the Suprarenal Capsules will be delivered by Professor A. E. Schäfer, F.R.S., on April 7th and 9th.

WATERSHEDS AND RAINFALL.

AT the annual meeting of the Royal Meteorological Society, which was held at the Institution of Civil Engineers on Jan. 15th, Dr. H. R. Mill, the President, delivered a most interesting address upon "Map Studies of Rainfall." Dr. Mill is the director of the British Rainfall Organisation, so that he dealt with a subject of which he possesses special knowledge. After describing the method of preparing annual, monthly, and daily maps of rainfall, he went on to draw attention to the extreme importance of accurate knowledge of the rainfall of a county, for the problem of the rivers is becoming acute. He added that the increasing strenuousness of the struggle for the possession of large water-supplies is producing in England, and especially in Wales, a great amount of local jealousy and strife, for the boundaries of parishes and counties coincide but rarely with water partings and the argument has been brought forward again and again that the rainfall of one county should not be diverted for the use of the inhabitants of another. But, continued Dr. Mill, "I think that the study of rainfall can do something to suggest the lines on which such disputes should be settled. ...... Most of the rain is borne to our islands from the Atlantic; ...... it is of the air, and no boundary checks it; the largest annual falls come down on and near the watersheds because there the land produces its maximum influence as a rain compeller." Therefore, concluded Dr. Mill, care for the water-supply of the country is by no means a parochial but in the fullest sense a national matter and should be dealt with in the interests of the nation as a whole, the units of subdivision when such are required being the natural units of river basins. We congratulate Dr. Mill upon his address which deals with a matter of the first importance. He shows that physical geography may be taken to afford as good an argument for the precipitation of the West being used to supply the great towns of the East of these islands as political geography may be taken to afford an opposite argument. London and the busy Welsh towns of Cardiff and Swansea are already arming for the fight for the possession of the Welsh watersheds. Liverpool has annexed the Vyrnwy district and Manchester the waters from Thirlmere. Unless that *congeries* of cities called London becomes injuring himself it was not likely that a fall would prove painless. The question how to provide exercise and amusement for a large number of pupils in the small space available in metropolitan and urban schools is not an easy one to answer. Games as understood in "public schools" are out of the question, and the suggestion made by Dr. McTurk in reply to a question of Mr. Justice Lawrance, who asked if he would recommend diabolo as a safe form of recreation, was to the effect that dumb-bell and bar-bell exercises would be suitable. The difficulty, however, of introducing exercises tending directly to physical development lies in the danger of their becoming merely an irksome and so an unpopular and a useless form of drill. Much, however, might be learned from the methods of training and of exciting emulation in such matters practised in Switzerland and elsewhere on the continent, and it may be suggested that competitions between the various schools in the London County Council's district held in the public parks might arouse sufficient spirit of rivalry to make physical training generally popular and so generally beneficial. In order to produce this result the competitions probably would have to be not between picked teams but between large bodies of the pupils consisting of all who had attained to a given degree of proficiency. The performance of such exercises is as least as manly a form of amusement as races "pick-a-back," and it may be pointed out that such combined displays of this nature as are seen annually at the Military Tournament are always a popular item in the programme.

CALMETTE'S OPHTHALMO-TUBERCULIN REACTION.

IN our issue of Feb. 1st we published a short note from our Paris correspondent dealing with the ophthalmo-tuberculin reaction described by M. Calmette and we now lay before our readers a fuller *résumé* of the paper read by M. Calmette, referred to by our Paris correspondent. M. Calmette said that in the short time which has elapsed since he communicated his discovery to the Academie des Sciences (June 17th, 1907), the almost absolute accuracy with which the reaction reveals the existence of tuberculous lesions *in evolution*, although manifested by no clinical signs, has been confirmed by numerous observers. Many observations have shown that the newly born children of tuberculous mothers do not give the reaction. On the other hand, infants at the age of from 1 to 2 years react in the proportion of 3·42 per cent. and the percentage increases rapidly with age. It is 5·26 at the ages of from 2 to 5 years, 13·5 at the ages of from 6 to 10 years, and 14·9 at the ages of from 11 to 15 years. These results are in accordance with the observations of Bang and Nocard that in cattle tuberculosis is scarcely ever congenital. By repeating the test sufficiently often M. Calmette suggests that the exact time at which tuberculosis attacks a child may be ascertained. By studying at the same time the conditions of the family and the food supply he thinks that the part played by family contagion (*contagion familiale*) and by the milk of tuberculous cows may be ascertained. By applying the test periodically to a family, or at least to those members in whom tuberculosis is feared, the infection may be detected at an early period, before even any clinical sign is perceptible. The patient may thus be isolated from his family and sent to a sanatorium and treated at the most favourable time. At the anti-tuberculosis dispensary of Emile Roux at Lille the test was applied to the children of families the members of which were under treatment. Thus children apparently healthy were ascertained to be tuberculous and were sent to the country and placed in the best hygienic conditions. At the same time they continued their school studies until the instillation of tuberculin into the eye, repeated every two or three months, no longer gave a reaction. They were then sent back to their families. M. Calmette thinks, with Marfan, that experiments on animals and the observations on patients discharged several years from sanatoriums show that the complete cure of chronic tuberculous glands confers immunity against tuberculosis. He therefore hopes that a great number of these children will remain immune. The reaction would be equally useful in the examination of pupils who seek admission to schools and are suspected to be tuberculous. Tuberculous pupils could thus be arrested "on the threshold"; in the army and navy the test could be put to a similar use. Professor Simonin of the military hospital of Val-de-Grâce has recently stated that the reaction reveals latent or insidious tuberculosis not evident clinically which provokes distant functional troubles of unknown causation. It thus enables patients suffering from dyspepsia, palpitation, neurasthenia, "atonic rheumatism," and so on, to be discharged from the military hospitals which they encumber. M. Calmette finally claimed that thanks to its fidelity and harmlessness, attested by more than 10,000 observations published in all countries, his reaction merited the confidence of clinicians and could play a great part in the social struggle against tuberculosis. By its use in families, in schools, in the army, in hospitals, and in all collections of persons those who were bearers of active tuberculous lesions could be detected.

THE LEES AND RAPER MEMORIAL LECTURE.

THE eighth Lees and Raper Memorial Lecture was delivered in the town-hall, Oxford, on Feb. 4th, by Mr. W. *McAdam Eccles*, under the presidency of the Regius Professor of Medicine, Dr. William Osler. The subject of the lecture was the Relation of Alcohol to Physical Deterioration and National Inefficiency. Mr. Eccles began by alluding to the action of alcohol upon living tissues, and then went on to quote figures from life assurance societies showing that total abstainers and their children were far better "lives" than those who took alcohol. Mr. Eccles went on to point out that alcoholic stimulants led to physical degeneracy and this in turn to inefficiency. Inefficiency of individuals led to inefficiency of the nation, and this in turn to loss of supremacy. He put forward the following suggestions to stem alcoholic indulgence: education of mothers and fathers, prohibition of the entrance of children into public-houses, feeding and teaching of the children of the land, limitation of the opportunities for adults to obtain liquor, the provision of sound recreation, and the promotion of research with the publication of its results. The numerous borough and parochial health societies springing into existence could do much to increase the knowledge of mothers. Municipal posters concerning the effects of the abuse of alcohol placarded on the hoardings were very valuable. The recent disclosures as to the results on child life of the entrance of children into public-houses called for immediate and adequate legislation. But it was folly if, when the child was kept free from alcohol, he or she were allowed to become stunted in growth from a want of sufficient and proper food. Some means must be devised whereby hungry school children should be fed. The instruction of the child in the elementary school was of the utmost importance. The elements of hygiene and temperance were vital, and they could be made very attractive to even the very young, if inculcated by a teacher of experience and ability. When a child had been taught these principles and had reached an age of discretion he or she should not be unduly tempted to fall from right paths by the continuance of a public-house at every street corner. If the public-house went something should take its place. What could be better than a happy home with a cheerful hearth, and a decent "winter garden" enabled to understand why adenoids are so frequently found in association with these deformities; for it is well known that individuals with leptoprosopic heads are more liable to give evidence of the effects of nasal obstruction on account of the narrowness of the nasal and naso-pharyngeal cavities than persons with chamæprosopic heads. Moreover, adenoids and other forms of nasal obstruction are, for some reason, far more common in leptoprosopes than in chamæprosopes. These facts therefore will help to explain how it is that the salient symptom of nasal obstruction (mouth-breathing) is noticed so frequently in conjunction with contracted alveolar arches. It is not, of course, that individuals with chamæprosopic heads enjoy an immunity from adenoids, but the symptoms do not develop in these subjects unless the collection of adenoid tissue in the naso-pharynx (which is indeed present in practically all children) has hypertrophied to a considerable extent."

THE METROPOLITAN STREET AMBULANCE SERVICE.

AMONGST the Parliamentary business connected with the public health and carried forward from last year the consideration of the street ambulance provision for London by a Departmental Committee holds a prominent place. As that body will shortly make public the result of its deliberations we will again remind our readers of the importance of providing easy and speedy means of transporting persons injured in the streets to the nearest general hospital and of the admirable model which the City police-force has given the metropolis by the institution of its motor ambulance service. In our issue of Nov. 23rd, 1907, p. 1474, we summarised in a leading article the history of the ambulance service for London, and on that occasion as on many others we pointed out the great measure in which the Metropolitan Street Ambulance Association has helped its development. The financial aspect, of course, must not be lost sight of in these days of municipal retrenchment, but a correspondent points out that the amount expended on ambulance work by the metropolitan police is very small in proportion to the sum paid to that body by the ratepayers. The official accounts show that in the financial year 1906–07 the metropolitan police received for all purposes £1,097,495 from the rates and expended on "medical attendance, medicines, &c., for prisoners and poor persons injured in public thoroughfares" £8098 13*s.* 5*d.* We are not in a position to state to what extent this connotes expenditure on street ambulance work, but in any case the sum can only be a small fraction of the total police expenses, and if the urgent need of a more efficient and better organised ambulance service than at present prevails were more widely understood we think that few ratepayers would object to the appropriation of a larger share of their police-rate to so humane a purpose. It is to be hoped that before the end of the year the motor ambulance van will be a familiar object outside the boundaries of the City of London.

HERPES FACIALIS IN DIPHTHERIA.

Dr. J. D. Rolleston has contributed to the *British Journal of Dermatology* for November an important paper on a complication of diphtheria which though not very rare has not received much attention—herpes facialis. Of 1370 cases of diphtheria, in all of which the diagnosis was verified bacteriologically, herpes labialis was present in 55 (4 per cent.). In the great majority (42) the lips alone were affected. Much less frequently the cheeks (six cases), the chin (four cases), and the nostrils (three cases) were attacked. Orsi, the only writer who has produced a monograph on the subject of herpes facialis in diphtheria, pointed out that the herpes frequently developed on the side on which the angina was predominant. This Dr. Rolleston has observed in some, but by no means in all, of his cases. The herpes was almost invariably an early symptom; it usually appeared on the third or fourth day; in only two cases did it appear after the first week. In non-diphtheritic angina Dr. Rolleston finds that herpes facialis is still more common. Out of 145 patients admitted into hospital and certified as suffering from diphtheria, who were ascertained subsequently to have only tonsillitis, herpes facialis occurred in 19 (13 per cent.). Among the acute infectious diseases for which figures are available as to the frequency of herpes facialis diphtheria ranks sixth. Pneumonia, malaria, and cerebro-spinal meningitis lead with a frequency for each of about 40 per cent.; influenza follows at a long distance with a frequency of 6 per cent.; and typhus fever with one of 5 per cent. Diphtheria follows and then typhoid fever with a frequency estimated from 1·3 to 3·5 per cent., relapsing fever (2½ per cent.), and finally small-pox (2 in 3000 cases). Herpes zoster is very rare in diphtheria; it occurs in only 0·1 per cent. of the cases. Dr. Rolleston found that herpes facialis was most frequent in severe cases of diphtheria (5·4 per cent. of the cases); least frequent in the moderate ones (4·7 per cent.); and less frequent in the mild (2·5 per cent.). The herpetic lesions healed rapidly, leaving no scar. They were not followed, as sometimes happens in herpes zoster, by paralysis of neighbouring structures. Paralysis of the lips occurred in 37 (2·7 per cent.) of the 1370 cases but it was present in none of the cases of herpes. As to the pathology of the herpes, Orsi regards it as a cutaneous manifestation of a reflex originating in the mucous membrane of the throat or nose from a toxic stimulus to the nerves. The greater frequency of herpes in severe cases of diphtheria lends support to this view. But it is difficult to understand why in non-specific angina in which the degree of toxæmia is less herpes is more frequent.

Sir Dyce Duckworth, M.D. Edin., F.R.C.P. Lond., will deliver an address before the Paris Faculty of Medicine on Feb. 18th, the title being "Les Diathèses le Facteur Personnel dans les Maladies." The address is to be given in French in the amphitheatre of the Faculty at 9.30 P.M., and Professor Landouzy, Dean of the Faculty, will be in the chair.

THE annual Hunterian oration will be delivered before the Fellows of the Hunterian Society by Mr. W. J. M. Ettles, at 8.30 P.M., on Wednesday, Feb. 12th, in the theatre of the London Institution, Finsbury-circus, E.C. The title is "The Renaissance of Ophthalmology during the Hunterian Period." All members of the medical profession are invited.

THE dinner of the West London Medico-Chirurgical Society will be held at the Hotel Great Central, London, on Thursday, Feb. 13th, at 7.30 P.M. The President, Mr. Richard Lake, will occupy the chair. Communications relating to the dinner should be addressed to Dr. F. G. Crookshank, 27, The Terrace, Barnes, S.W.

THE first of the three Lettsomian lectures was delivered by Mr. C. J. Symonds on Feb. 3rd at a meeting of the Medical Society of London. Mr. Symonds took as his subject Tuberculosis of the Kidney and we hope in a later issue to publish a full report of his interesting lecture.

WE regret to announce the death on Tuesday morning, Feb. 4th, of Mr. William Allingham, F.R.C.S. Eng. Mr. Allingham, who was formerly surgeon to the Great Northern Central Hospital and St. Mark's Hospital, had a great the "starter," and the grains can be covered with milk and set in a cool place until the next day. The "starter" is then mixed with 188 cubic centimetres of boiled milk in a bottle which should not be completely filled. The bottle is corked immediately and kept at a temperature of 20° to 23° C. until the liquid begins to thicken. This process requires from 18 to 25 hours in winter and from 14 to 20 hours in summer. The thickened liquid is then agitated vigorously and kept in a cellar at 9° to 12·5° C., the agitation being repeated every two hours. Kefir is known as "day old," "two day old," and "three day old," according to the time allowed for fermentation. The longer the grains are used the better is the quality of the product. Kefir so prepared possesses a pleasant, refreshing, and slightly acid taste. By prolonging the period of fermentation the alcohol and carbon dioxide are increased and a more thorough peptonisation is secured. Kefir may be combined with ferric lactate or pepsin for administration in anæmia and dyspepsia.

MEDICAL FEES AT CORONERS' INQUESTS.

THE Lancashire county council has come to the decision to pay in the future only 1 guinea per inquest to medical practitioners attending to give evidence, even if several days are required for the completion of the inquiry. In support of this decision the clerk of the council refers to Section 22 of the Coroners Act, 1887, which governs the question of fees to medical witnesses, making reference, we presume, only to the giving of evidence and not to the making of post-mortem examinations. This is a momentous decision of the council and we are not surprised to find our esteemed contemporary the *Liverpool Courier* asking "if the county financiers are right in their reading of the Coroners Act, how is it the discovery has been so long delayed?" and adding: "perhaps the committee has reached an interpretation which the legislature never contemplated?" Looking carefully at the wording of the Act we are compelled to agree that the interpretation of the finance committee of the Lancashire county council may be literally correct, for we cannot find anything definite in the Act as to additional medical fees for protracted work. Doubtless the legislature had in mind that an inquest seldom occupies more than one day and that the coroner could easily make arrangements for additional medical assistance. At the same time the attitude of the Lancashire county council may eventually lead to a result which they hoped to avoid—viz., the undue swelling of expenses. Supposing, for instance, that a medical practitioner has obeyed the coroner's summons—if he does not he renders himself liable to a fine of £5, attends on the first day and gives evidence, and then is re-summoned by the coroner on a subsequent day we are inclined to think that he would be entitled to demand an extra guinea. Of course, the coroner, the servant of the county council, might have to pay the fee out of his own pocket or fight a pretty point on behalf of the medical profession, and we are not so unreasonable as to expect that he should be invited to do anything of the sort. But it is certainly ridiculous that should a prisoner be tried at the assizes on a coroner's inquisition alone the medical witness would be entitled to the ordinary fees allowed for attendances in criminal courts, while according to the recent decree of the Lancashire county council he would only receive 1 guinea for employing an equal or a greater amount of valuable time while attending the preliminary proceedings before the coroner. It is pleasant to read the forcible opinion of Mr. Coroner Brighouse, who is a solicitor, and his condemnation of the slight on the medical profession. The subject is worthy of the attention of all our readers, for the precedent may be followed by other county councils to the detriment of a profession already burdened with many inadequately paid duties. We are grateful to the *Liverpool Courier* for its evidently sympathetic attitude towards the medical profession, for we have to remember that a certain section of the press owes an appreciable portion of its revenue to the misrepresentation of our calling.

* A day with at least 0·04 in.

The rather prolonged spells of frosty weather which prevailed over the United Kingdom during last month paid only transitory visits to Southern Europe, while Palmero, Malta, Algiers, and Lisbon escaped the frost altogether. The Scilly Islands experienced a like exemption, but over this country generally, and throughout Central Europe, the Low Countries, and the north and east of France the cold was often very severe. Although over the northern half of Italy the wintry rigour was reduced by the proximity of the Mediterranean, the sheltered thermometer descended to the freezing point or below it on nine different nights at Rome and on 16 at Florence. In comparing the temperature at places in the south of these islands with that in Southern Europe it will be observed that the figures at Scilly were almost identical with those at Genoa, while the nights at Scilly (as shown by the mean minimum temperature) were no less than five degrees warmer than those at Nice and Rome, nine degrees warmer than those at Florence, one degree warmer than those at Biarritz, and only just one degree cooler than those at Naples and Palermo. The warmth of the days was, however, far greater at nearly all the resorts on the shores of the Mediterranean, especially at Palermo, Malta, and Algiers. At this last-mentioned place the nights were as mild as the afternoons were at Bournemouth, Bath, and in London, and the days were as warm as the average day in the south of England towards the end of May. Paris, Berlin, and Brussels were all much colder than London and the English Midlands, the mean temperature of the month at enabled to understand why adenoids are so frequently found in association with these deformities; for it is well known that individuals with leptoprosopic heads are more liable to give evidence of the effects of nasal obstruction on account of the narrowness of the nasal and naso-pharyngeal cavities than persons with chamæprosopic heads. Moreover, adenoids and other forms of nasal obstruction are, for some reason, far more common in leptoprosopes than in chamæprosopes. These facts therefore will help to explain how it is that the salient symptom of nasal obstruction (mouth-breathing) is noticed so frequently in conjunction with contracted alveolar arches. It is not, of course, that individuals with chamæprosopic heads enjoy an immunity from adenoids, but the symptoms do not develop in these subjects unless the collection of adenoid tissue in the naso-pharynx (which is indeed present in practically all children) has hypertrophied to a considerable extent."

THE METROPOLITAN STREET AMBULANCE SERVICE.

Amongst the Parliamentary business connected with the public health and carried forward from last year the consideration of the street ambulance provision for London by a Departmental Committee holds a prominent place. As that body will shortly make public the result of its deliberations we will again remind our readers of the importance of providing easy and speedy means of transporting persons injured in the streets to the nearest general hospital and of the admirable model which the City police-force has given the metropolis by the institution of its motor ambulance service. In our issue of Nov. 23rd, 1907, p. 1474, we summarised in a leading article the history of the ambulance service for London, and on that occasion as on many others we pointed out the great measure in which the Metropolitan Street Ambulance Association has helped its development. The financial aspect, of course, must not be lost sight of in these days of municipal retrenchment, but a correspondent points out that the amount expended on ambulance work by the metropolitan police is very small in proportion to the sum paid to that body by the ratepayers. The official accounts show that in the financial year 1906–07 the metropolitan police received for all purposes £1,097,495 from the rates and expended on "medical attendance, medicines, &c., for prisoners and poor persons injured in public thoroughfares" £8098 13*s.* 5*d.* We are not in a position to state to what extent this connotes expenditure on street ambulance work, but in any case the sum can only be a small fraction of the total police expenses, and if the urgent need of a more efficient and better organised ambulance service than at present prevails were more widely understood we think that few ratepayers would object to the appropriation of a larger share of their police-rate to so humane a purpose. It is to be hoped that before the end of the year the motor ambulance van will be a familiar object outside the boundaries of the City of London.

HERPES FACIALIS IN DIPHTHERIA.

Dr. J. D. Rolleston has contributed to the *British Journal of Dermatology* for November an important paper on a complication of diphtheria which though not very rare has not received much attention—herpes facialis. Of 1370 cases of diphtheria, in all of which the diagnosis was verified bacteriologically, herpes labialis was present in 55 (4 per cent.). In the great majority (42) the lips alone were affected. Much less frequently the cheeks (six cases), the chin (four cases), and the nostrils (three cases) were attacked. Orsi, the only writer who has produced a monograph on the subject of herpes facialis in diphtheria, pointed out that the herpes frequently developed on the side on which the angina was predominant. This Dr. Rolleston has observed in some, but by no means in all, of his cases. The herpes was almost invariably an early symptom; it usually appeared on the third or fourth day; in only two cases did it appear after the first week. In non-diphtheritic angina Dr. Rolleston finds that herpes facialis is still more common. Out of 145 patients admitted into hospital and certified as suffering from diphtheria, who were ascertained subsequently to have only tonsillitis, herpes facialis occurred in 19 (13 per cent.). Among the acute infectious diseases for which figures are available as to the frequency of herpes facialis diphtheria ranks sixth. Pneumonia, malaria, and cerebro-spinal meningitis lead with a frequency for each of about 40 per cent.; influenza follows at a long distance with a frequency of 6 per cent.; and typhus fever with one of 5 per cent. Diphtheria follows and then typhoid fever with a frequency estimated from 1·3 to 3·5 per cent., relapsing fever (2½ per cent.), and finally small-pox (2 in 3000 cases). Herpes zoster is very rare in diphtheria; it occurs in only 0·1 per cent. of the cases. Dr. Rolleston found that herpes facialis was most frequent in severe cases of diphtheria (5·4 per cent. of the cases); least frequent in the moderate ones (4·7 per cent.); and less frequent in the mild (2·5 per cent.). The herpetic lesions healed rapidly, leaving no scar. They were not followed, as sometimes happens in herpes zoster, by paralysis of neighbouring structures. Paralysis of the lips occurred in 37 (2·7 per cent.) of the 1370 cases but it was present in none of the cases of herpes. As to the pathology of the herpes, Orsi regards it as a cutaneous manifestation of a reflex originating in the mucous membrane of the throat or nose from a toxic stimulus to the nerves. The greater frequency of herpes in severe cases of diphtheria lends support to this view. But it is difficult to understand why in non-specific angina in which the degree of toxæmia is less herpes is more frequent.

Sir Dyce Duckworth, M.D. Edin., F.R.C.P. Lond., will deliver an address before the Paris Faculty of Medicine on Feb. 18th, the title being "Les Diathèses le Facteur Personnel dans les Maladies." The address is to be given in French in the amphitheatre of the Faculty at 9.30 P.M., and Professor Landouzy, Dean of the Faculty, will be in the chair.

The annual Hunterian oration will be delivered before the Fellows of the Hunterian Society by Mr. W. J. M. Ettles, at 8.30 P.M., on Wednesday, Feb. 12th, in the theatre of the London Institution, Finsbury-circus, E.C. The title is "The Renaissance of Ophthalmology during the Hunterian Period." All members of the medical profession are invited.

The dinner of the West London Medico-Chirurgical Society will be held at the Hotel Great Central, London, on Thursday, Feb. 13th, at 7.30 P.M. The President, Mr. Richard Lake, will occupy the chair. Communications relating to the dinner should be addressed to Dr. F. G. Crookshank, 27, The Terrace, Barnes, S.W.

The first of the three Lettsomian lectures was delivered by Mr. C. J. Symonds on Feb. 3rd at a meeting of the Medical Society of London. Mr. Symonds took as his subject Tuberculosis of the Kidney and we hope in a later issue to publish a full report of his interesting lecture.

We regret to announce the death on Tuesday morning, Feb. 4th, of Mr. William Allingham, F.R.C.S. Eng. Mr. Allingham, who was formerly surgeon to the Great Northern Central Hospital and St. Mark's Hospital, had a great alive to the situation her citizens may soon have cause to complain with the chorus in Medea:—

> ἄνω ποταμῶν ἱερῶν χωροῦσι παγαί,
> καὶ δίκα καὶ πάντα πάλιν στρέφεται.

We must not be taken to imply that the Welsh scheme which has been put forward is the only solution of the problem but it is certain that the river water-supply at present available will not suffice for the population of 50 years hence. Our views on the matter were set forth at large in a leading article which appeared in THE LANCET of Dec. 14th, 1907.

INFANT MORTALITY IN HUDDERSFIELD.

A STRIKING report by Dr. S. G. Moore, medical officer of health of the borough of Huddersfield, has been published by the borough council. The report shows the result of the systematic work which has been done in Huddersfield with the intention of lowering infant mortality, and the figures for the year 1907 show the conspicuous success which has attended the efforts of Dr. Moore and his authority. During 1907, 2189 births occurred in the borough, and 212 infants less than 12 months old died, giving an infant mortality figure of 97. The records of the department extend back for 31 years, and how very successful the work has been will be perceived when we say that the present figure 97 is not only the lowest on record—the figure for the first time having fallen below 100—but the mean for the *ten preceding* years, 1897 to 1906 inclusive, was 135. *Thus there has been* effected a reduction of 28 per cent. The mean for the three years 1905-06-07 during which the work has been in *progress* is 117, and for the ten years preceding this, 1895 to 1904 inclusive, it was 142. The figures are shown on a chart which accompanies the report and are further summarised as below:—

—	Births registered.	Deaths under one year of age.	Infant mortality figure.	—
1907	2,189	212	97	Reduction 28 per cent.
Preceding 10 years 1897-1906	22,931	3104	135	—
The three years during which special work against infant mortality has been in progress, 1905-06-07	6,746	792	117	Reduction 18 per cent.
Preceding 10 years, 1895-1904	22,681	3215	142	—

Huddersfield, as Dr. Moore points out, is an industrial centre with not less than 25 per cent. of the *female population* at child-bearing ages working in textile factories. It is therefore the more surprising to find the infant mortality figure reduced to a rate comparable with that of the healthiest counties and rural districts. We congratulate all concerned on the result of their labours and hope that other authorities may be stimulated to similar exertions.

HÆMO-PERICARDIUM FROM RUPTURE OF A CORONARY ARTERY.

APART from those cases which are due to injury, nearly all *instances of fatal* hæmo-pericardium are due to the bursting of an aneurysm arising from the heart itself. Very much more rarely is a hæmo-pericardium produced by an aneurysm of the coronary artery. In the present issue of THE LANCET Mr. J. Lougheed Baskin records a case in which a fatal hæmorrhage into the cavity of the pericardium resulted from a gummatous deposit in the wall of the heart involving the left coronary artery about one and a half inches from its origin; the artery had given way but no obvious aneurysmal dilatation was seen. Death in these cases of hæmo-pericardium always results from direct pressure of the effused blood on the heart. As the blood poured out from the left ventricle or *from a coronary* artery will exert almost the same hydrostatic pressure as that present in the left ventricle the pressure in the pericardium will be much greater than that in the intrapericardial portions of the venæ cavæ; so that these are compressed and no blood can enter the heart and syncope follows. The quantity of blood lost has practically nothing to do with the fatal result, for the total amount of blood which can be poured out into a normal pericardium is but small.

THE DEATH OF MR. W. A. SHENSTONE, F.R.S.

THE death of Mr. W. A. Shenstone, F.R.S., will be very widely regretted by chemists and physicists alike. He will be remembered most perhaps for his consummate skill at glass-blowing, which ultimately led the way to the use of pure silica or quartz for purposes of chemical research. Silica vessels are now a commercial quantity, and since this beautiful material resists the action of extreme changes of temperature and is also unaffected by acids it threatens to replace the use of expensive platinum apparatus in many chemical operations. Mr. Shenstone was an able investigator of chemical science and contributed a number of valuable papers to the scientific societies. He was senior science master to Clifton College, Bristol, for 27 years, a post which he held up to the time of his death which took place in Cornwall on Feb. 3rd. He possessed a charming personality which contributed no little to his power as a teacher of principles and practice. His attitude *towards* science is well summed up in a very able *series of essays on* the new physics and chemistry which were published in the *Cornhill Magazine* a year or so ago. "Though science," he wrote, "reveals herself to most of us chiefly through her more obviously useful discoveries and inventions, those who look for them will still find amongst us not a few men and women as ready as any of their predecessors to devote days and nights to hard labour for no other fee than the hope of discovering a new truth, overthrowing an ancient error, or extending in some other way the boundaries of knowledge." Mr. Shenstone was amongst the great labourers of science.

THE RELATION OF ADENOIDS TO PALATAL DEFORMITIES.

IN the course of a suggestive paper in the *Dental Record* for January, Dr. Eugene S. Yonge refers at some length to the interesting question of the relation of adenoids to palatal deformities. The more important theories that have been advanced are briefly recounted, but in his opinion not one of them offers a satisfactory explanation. Some stress is laid on the fact that a large number of patients show deformed arches who are not, and never have been, mouth-breathers, while on the *other* hand such deformities are often entirely absent in those the subjects of well-marked nasal *obstruction. Reference is* made to the frequent association of high arched and contracted palate and associated anomalies in people with *long narrow* faces and to the view held by some that *this* type of face is a departure from the normal and may be hereditary. Dr. Yonge is of the opinion that the *adenoids* and deformed palates are not in causal relationship but are rather due to a common cause, and as an explanation of this frequent association he suggests "that if we assume that the deformities of the palate are principally due to an abnormality, which is of a hereditary or constitutional or even racial character, affecting the structure of the facial bones, we are enabled to understand why these defects may occur *independently* of mouth-breathing and why mouth-breathing of itself does not *tend to* them. We are also quotation here. He says: "The acceptance of the view that under conditions which exist in urban populations, the susceptibility of the individual, and not the exposure to, known cases of phthisis, govern the probability of attack does not of itself negative the theory of the infectivity of tuberculous phthisis. It does, however, raise serious question as to the practicability of reducing the rate of phthisis mortality by efforts to segregate persons suffering from this disease, even if the theory of infection from person to person is accepted as the common way in which susceptible persons are infected. However this may be, it may undoubtedly be stated that our knowledge of the subject at the present time is insufficient to justify the introduction into London of a system of compulsory segregation."

The London statistics of mortality from cancer or malignant disease agree generally with those of other parts of the United Kingdom in that they indicate a continuously increasing fatality from this terrible malady, from the earliest recorded dates to the present time. From a table in the report it appears that whilst in 1851–60 the average loss of life in the metropolis from malignant diseases was equal to 42 in each 100,000 of the population at all ages and of both sexes, in the year 1906 the proportion had risen to 98 in the same number living.

In order to obtain precise information concerning the local incidence of cancer factors have been calculated for correcting as far as possible the rates of mortality for the several sanitary areas of the metropolis; but owing to changes in these areas caused by the London Government Act of 1899 the death-rates since 1900 are alone available for comparative purposes. The average death-rates from cancer in the years 1901–05 are presented in another table which shows that the highest mortality (1·10 per 1000) occurred in the City of London, the lowest rates obtaining in Finsbury and in Greenwich, where they were 0·84 per 1000. In yet another table an attempt is made to ascertain the relation of overcrowding to cancer incidence in various districts of London, the object being to compare the death-rates of sections of the people differently circumstanced socially. But although the numbers dealt with are considerable the differences in the local death-rates, compared according to this method, are less pronounced than might have been expected.

Puerperal fever, under which name are included the deaths from pyæmia and septicæmia occurring in connexion with the puerperal state, was fatal to 187 women in the course of the year 1906, the number notified as suffering from affections of this nature being 298. The subject of puerperal sepsis has come to assume additional interest because of the steps that are now practicable under the Midwives Act of 1902 for diminishing the perils of childbirth. From data in the report it appears that in the year 1906 the number of midwives on the London registers was 2350, less than 8 per cent. of whom are returned as "uncertified." The actual proportion, however, must be greater than this, for the majority of enrolled midwives are not practising. Many of them are engaged as monthly nurses and many more are on the staffs of hospitals. Interesting details are given in the report as to the number of female medical inspectors appointed under the Midwives Act and also as to the duties which they perform. In the administration of this Act in London the authorities appear to have been assiduous.

All cases of puerperal fever where a midwife is known to have been in attendance are investigated. For this purpose early intimation of all cases of puerperal fever is received by telephone from the Metropolitan Asylums Board and weekly lists of deaths from puerperal sepsis are obtained from the Registrar-General. Of the 187 deaths registered as from puerperal fever 68 referred to cases that had not been notified as suffering from that disease; it would therefore appear probable that in spite of the compulsory nature of the Notification Act many cases of puerperal fever, in its wider sense, which do not prove fatal, are never officially notified. Incidentally the investigations under the Act have served to ascertain the proportion of stillbirths to total children born. For the metropolis this is seen to average from 3 to 4 per cent.

(*To be continued.*)

DEATH OF A CENTENARIAN.—Mrs. Honor Coleman, who died recently at Yatton, Somersetshire, celebrated the 106th anniversary of her birth on Feb. 22nd, 1907. The old lady's mother and grandmother were also centenarians.

NOTES UPON HEALTH RESORTS.

ALGECIRAS AND ITS CLIMATE.

By A. W. W. DOWDING, M.D. DURH., M.R.C.P. EDIN.

THE Algeciras-Gibraltar Railway, which has its sea terminus at the quaint old town of Algeciras, Spain, right opposite Gibraltar, and its capital entirely English, has been the means of opening up the neighbouring district not only by its railway and steamer communications but also by means of the new Hotel Reina Cristina, Algeciras, which was built in 1901 and has since been enlarged. The district itself for its climate, scenery, and objects of archæological interest is difficult to surpass, and within three hours by rail is the inland town of Ronda, situated on a lofty plateau about 2400 feet above the sea level and practically surrounded at a distance with a panorama of high mountains. Here the air is very dry and bracing. And the company is building another hotel in conjunction with the Reina Cristina which will be opened shortly.

As regards the climate of Algeciras—the most southerly health resort in Europe—it is milder, warmer, and more equable than that of the Riviera, Algiers, and Morocco. In north latitude 36° 6′ 20″ and in west longitude 5° 20′ 53″ it is practically in the line of latitude with Algiers and Malta and is about 4° north of Madeira and further south than the Riviera. Beautifully situated on the Bay of Gibraltar, the surrounding country is undulating and the soil is light and porous so that the roads soon dry up after rain. Being located near the junction of the Mediterranean and the
Atlantic Ocean at a point where two great continents m
it naturally follows that its climate must be influenced m
or less by each of these elements. The water-supp

A TELEGRAM from the Acting Governor of the Gold Coast, received at the Colonial Office on Jan. 31st, states that on Jan. 30th there were 2 deaths from plague, 14 natives were in hospital, and 19 were isolated.

ANNUAL REPORT FOR 1906 OF THE MEDICAL OFFICER OF HEALTH OF THE ADMINISTRATIVE COUNTY OF LONDON.[1]

II.

CONTINUING our review of this report, we observe that Sir Shirley Murphy devotes particular attention to the behaviour of the mortality from pulmonary tuberculosis in recent years, especial regard being paid first to the relative prevalence of the disease in different sections of the community; next, to the effect of overcrowding on it fatality; and lastly, to an examination of some current theories concerning the mode of infection by pulmonary tuberculosis and of the several methods suggested for the prevention or suppression of the malady.

In the year 1906 the mortality caused by pulmonary tuberculosis in the metropolis was equal to a rate of 1·44 per 1000 persons living, without reference to age or sex; it was therefore higher than the average rate for England and Wales by 0·29 per 1000. A table in the report shows that in the year under notice pulmonary tuberculosis was not more than half as fatal in London as it had been in the decade 1851–60, the earliest period for which trustworthy records exist. From an interesting diagram we learn that the male death-rate from pulmonary tuberculosis during the last half century has averaged 2·90 per 1000, or almost exactly 1 per 1000 above the female rate. Since the year 1880, however, the rate in both sexes has been constantly below the average, the female rate having apparently declined faster than the male.

Very interesting is the table showing the distribution of fatal pulmonary tuberculosis in the several metropolitan boroughs; it is unquestionably trustworthy, for in its construction care has been taken not only to refer institution deaths to the districts from which the patients originally came but to correct the death-rate of each borough for differences in the age and sex constitution of the living. From the last two columns in the table which show the mortality in the several boroughs as compared with that of the county of London, taken as 1000, we learn that 11 of the 29 boroughs had in 1901–05 an average mortality in excess of the county rate. In the year 1906 this was again the case, the rates in certain boroughs being above the county rates in some instances by from 20 to 70 per cent. In the years 1901–05 pulmonary tuberculosis was most fatal in Holborn, where the corrected rate was 2·58 per 1000, in Southwark 2·40, and in Bethnal Green 2·28 per 1000. As in previous years, Hampstead appears most favourably in the list, the rate there being only 0·82 per 1000, as compared with 1·57 in the county of London.

With respect to the influence of overcrowding in determining the relative fatality from pulmonary tuberculosis, there is a highly instructive table in the present volume, the like of which we should like to see included in the reports of medical officers of health outside the metropolis. This table shows that after making due allowance for age differences among the living, the mortality from pulmonary tuberculosis varies from a rate of 1·1 per 1000 in the least overcrowded sanitary areas to precisely double that rate in the areas where the overcrowding exceeds 27·5 per cent.

Elsewhere in the report comparison is instituted between the death-rate from pulmonary tuberculosis in the new model dwellings built by the County Council and that in London generally. In these dwellings at any rate, it may be presumed that the Council has taken adequate precautions against overcrowding. The figures now available are for one year only and relate to the mortality among not more than 21,000 tenants. Still, as far as they go, they are encouraging, for they indicate a reduction in the mortality from pulmonary tuberculosis of 14 per cent. as compared with that of other dwellers in the metropolis.

As regards statistics of mortality in different social strata of the population we have before commented on the advantage possessed by portions of Ireland over other parts of the United Kingdom. Sir Robert Matheson, the Registrar-General for Ireland, has, for many past years, published rates of mortality among different grades of the Irish people, and, as might be expected, these rates show remarkable disparity. Sir Shirley Murphy evidently appreciates the need for similar means of distinguishing between class and class in London; for, in the present report he presents a table showing the degree in which the dwellers in common lodging houses suffer from pulmonary tuberculosis, in contrast with other inhabitants of the metropolis. Since the year 1902 the administrative control of London common lodging houses has devolved on the County Council; and the medical officer of health has taken pains to inform himself as nearly as practicable concerning the effect of residence in such dwellings on the health of the lodgers. But in this attempt he is met by the difficulty that the mortality from separate diseases cannot satisfactorily be presented in terms of population, because of the extreme variations in the numbers living, from time to time; he therefore prefers to rely on the deaths from specified diseases in proportion to the deaths from all causes. From a table in which this alternative has been adopted we learn that of the total deaths of inmates of common lodging-houses, at ages 25–35 years, 54 per cent. were attributed to pulmonary tuberculosis, as against 40 per cent. in London generally; at ages 35–45 the percentages were 53 and 31 respectively; at ages 45–55 they were 48 and 23; and at ages 55–65 they were 31 and 12; whilst at ages above 65 the proportions were 11 per cent. in common lodging-houses as against 3 per cent. elsewhere in London.

As regards measures either in operation or in contemplation for limiting the prevalence of tuberculous disease, this report contains a section that will amply repay perusal. Abundant evidence is produced to show that there is a growing demand for really effectual methods of dealing with the disease over and above the ordinary expedients of isolation and disinfection usually adopted for the suppression of the acute infectious disorders. A system of voluntary notification of pulmonary tuberculosis obtains in many of the sanitary districts and this is generally followed by disinfection and by visits to the house, with advice as to precautions to be taken by the sufferer. In a few instances compulsory notification, with compulsory removal of advanced cases, has been advocated by medical officers of health. But on this point Sir Shirley Murphy insists, in our opinion, most justly, that the "latter view is more advanced than that which is actually held. It becomes therefore very necessary to examine the grounds for such a demand, which, if fully acted upon, would deprive of their liberty many thousands of persons in London." The current theories concerning infection on the one hand and heredity on the other which have been advanced to account for the incidence of pulmonary tuberculosis are ably discussed in the report. Reference is made to the opinions of Professor Karl Pearson who has specially studied this subject, utilising for this purpose the facts relating to 384 families in which cases of pulmonary tuberculosis had occurred. Professor Pearson found that the number of tuberculous married *persons* who had a tuberculous mate was not sufficiently great to require an appeal to infection in order to account for this number; but what he did find was that the condition which governed the liability to attack was heredity of the diathesis of pulmonary tuberculosis. "A theory of infection," he writes, "does not account for the facts. I am inclined to think that the risks run, especially under urban conditions, are, for tuberculosis as for a number of other infectious diseases, so great that the constitution or diathesis means almost everything for the individual whose life cannot be spent in self-protection; I feel fairly certain that for the artizan class the inheritance factor is far more important than the infection factor, because in a very large proportion of cases it does not lie in the power of the individual to maintain, in the stress of urban life, a wholly safe environment."

The passage in which Sir Shirley Murphy summarises his own conclusions on this important subject is worthy of on such railway, and the railway company are not therefore liable to the surgeon for services rendered to such passenger under a contract so entered into (Cox *v.* The Midland Railway Co., 18 L J. Ex., 65). Nor does the new Workmen's Compensation Act make the master liable for medical attendance on a servant in case of accident. Of course, some masters insure their servants in such a way as to cover medical expenses up to £5 but the law does not impose any obligation on them to do so. Suppose a caretaker of a country house falls downstairs in the absence of the family and is laid up for some weeks with concussion of the brain. A medical man is called in by one of the servants to attend her. Is the master liable? The answer is "No." There is no doubt that as time goes on the provisions of the Workmen's Compensation Act will be extended to cover medical expenses. If the principle of compensation for injuries is once admitted it seems absurd to limit the compensation to particular employments, as was the case before 1906, and if compensation has now to be paid to all servants for accidents it seems anomalous not to make the master liable for medical expenses. In the above case supposed the caretaker might have become unconscious and seriously ill for four or five days, but if she recovered and was able to do her work again by the thirteenth day she would only be entitled to recover compensation for one week which in no case can exceed £1 a week and yet the medical expenses she had to pay may have far exceeded that amount.

The Health and Safety of Young Children.

Several cases affecting the health and the lives of little children have recently been reported in the newspapers showing a strong intention on the part of those administering the law to protect this helpless section of the community from the various dangers always threatening it. In the recent bitterly cold weather Mr. Denman had before him at Marlborough-street a man, 30 years of age, who was charged with exposing his son, aged four and a half years, in a way likely to cause injury to his health. The child was placed on an organ which his father and another man were wheeling about for the purpose of obtaining money. Mr. Denman called attention to the number of children thus made use of in severe weather for the iniquitous purpose of extracting alms from kind-hearted but mistaken persons and to the law which enabled him to punish the conduct of adults who so subjected them to danger and suffering. He expressed his determination to make the case an example and a warning to parents and others and sent the defendant to prison for a month with hard labour. A street organ formed the means by which the male defendant in another case "earned" his living. He and his wife were charged with neglecting four children whose ages ranged from six years to 14 months. Their plan was not to take them out in the streets but to leave them locked up without food, fire, or sufficient clothing. A story was told apparently involving conjugal infidelity on the part of both parents, and there was an allegation of fear of her husband on the part of the wife, but the learned magistrate looked on the cruelty proved as sufficiently serious to warrant the infliction of sentences of six months' imprisonment on the man and of four months on the woman. At Bradford James Taylor, a labourer in the employment of the corporation, had beaten with shocking brutality his little girl, seven years of age, and his son, 13 years of age, besides nearly strangling the latter. He received sentences amounting to 12 months' hard labour, accompanied by the expression of the opinion of the chairman of the bench that he was a dastardly blackguard. In the first case mentioned above the police are to be congratulated upon the vigilance of a constable; in the second and third the National Society for the Prevention of Cruelty to Children conducted the prosecution and obtained well-deserved success. Among recent inquests showing the dangers which beset children may be noted one at St. Pancras at which it was proved that Daisy Bell, six years of age, owed her death to her flannelette nightdress catching fire at a grate not protected by any fireguard. Mr. W. Schröder, the coroner, called attention to the Bill which proposes to make the omission to provide a fireguard punishable as criminal neglect where a child has died in consequence and expressed a hope that the measure might be reintroduced with success during the coming session. At another inquest held at Kingston it was proved that a little girl, aged eight weeks, had been fed on boiled bread when her mother found that the child would not take the breast. The body of the infant thus starved to death weighed 5½ pounds and the coroner, Mr. Michael H. Taylor, after referring to the number of deaths of children from malnutrition as "appalling," expressed the wish that girls might be taught at school more that would be useful to them in domestic life, even if they learnt less about other subjects of a more strictly scholastic character. While the sympathy of all is rightly invoked for children wantonly neglected and ill-treated allusion may be made to the observations of Sir Horatio Davies uttered recently at the Guildhall police court in connexion with the generous efforts of strangers to aid children and others whose cases are made prominent through the evidence of their destitution given in the law courts. In thanking the press and the public on behalf of a case of genuine poverty and suffering, he pointed out with reference to it and to that of several children then before him who had been found wandering in the City that there was a risk of encouraging evilly disposed parents to send out their children to beg with a view to their being brought to the police court and so exciting sympathy. Two other recent cases serve to illustrate the difficulties against which the National Society for the Prevention of Cruelty to Children and those who sympathise with its efforts have to contend where deliberate cruelty can hardly be attributed to the parents but rather physical and mental incapacity to fulfil their duties. In the first instance the mother of two children of the respective ages of six and three years was said to be blind and quite incapable of cleansing or taking care of them. She spent her days sitting about in the streets, presumably in order to excite sympathy and to collect alms, and it was further stated that her husband, a man 62 years of age, ill-treated her and refused to look after his offspring. Summoned at the North London police court he was sentenced to three months' hard labour for his neglect. In the other case an inquest was held upon an infant, three months old, one of twins, who, according to the evidence of Dr. Henry S. Souttar, house physician at the London Hospital, had been starved to death by the mother's neglect. The other child present at the inquest in his mother's arms was shown to the coroner, Mr. Wynne Baxter, who expressed horror at his condition, and finding the mother's answers to his questions unsatisfactory, pursued his inquiries with regard to her until he discovered that she had recently been an inmate of Claybury Asylum. He expressed the opinion that she was on the borderland between sanity and insanity and expressed his intention of communicating with the National Society for the Prevention of Cruelty to Children.

FIVE YEARS' EXPERIENCE OF A RECEPTION HOUSE FOR RECENT CASES OF INSANITY.

BY HAMILTON C. MARR, M.D. GLASG., F.F.P.S. GLASG.,
MEDICAL SUPERINTENDENT, GLASGOW DISTRICT ASYLUM, WOODILEE, LENZIE; MACKINTOSH LECTURER ON INSANITY, ST. MUNGO'S COLLEGE, GLASGOW.

THE question of the provision of increased accommodation at Woodilee Asylum was brought before the Glasgow District Lunacy Board in the latter part of the year 1900. In a report submitted to the board it was urged, among other considerations, that the required accommodation should embrace (1) a reception house; (2) a sanatorium for the consumptive insane; and (3) a nurses' home. This accommodation the board decided to provide. The reception house and sanatorium, which are similar in design, were opened for the admission of patients on Dec. 25th, 1902 and the nurses' home for 110 nurses was opened on Sept. 15th, 1904. Of the two former buildings I confine my description to the reception house as my main object in writing this paper is to give an account of the work that has been and is being done in it.

The reception house is situated about a quarter of a mile from the main administrative centre and is about 200 feet above sea level. It is, in some respects, unique, and has been the object of much interest during the five years in which it has been in operation. It presents those special features: (1) its construction is that of an ordinary hospital; (2) the provision of verandahs permits of the advantages of the open-air treatment; (3) all newly admitted patients are received into it; (4) patients whose illness is of short duration are allowed to remain and thus avoid the necessity of their being sent to the main asylum; and (5) the nursing is mainly done by women. The building consists of three reputation as author and practitioner in his special line of surgery.

A TELEGRAM from the Acting Governor of the Gold Coast, received at the Colonial Office on Jan. 31st, states that on Jan. 30th there were 2 deaths from plague, 14 natives were in hospital, and 19 were isolated.

ANNUAL REPORT FOR 1906 OF THE MEDICAL OFFICER OF HEALTH OF THE ADMINISTRATIVE COUNTY OF LONDON.[1]

II.

CONTINUING our review of this report, we observe that Sir Shirley Murphy devotes particular attention to the behaviour of the mortality from pulmonary tuberculosis in recent years, especial regard being paid first to the relative prevalence of the disease in different sections of the community; next, to the effect of overcrowding on it fatality; and lastly, to an examination of some current theories concerning the mode of infection by pulmonary tuberculosis and of the several methods suggested for the prevention or suppression of the malady.

In the year 1906 the mortality caused by pulmonary tuberculosis in the metropolis was equal to a rate of 1·44 per 1000 persons living, without reference to age or sex; it was therefore higher than the average rate for England and Wales by 0·29 per 1000. A table in the report shows that in the year under notice pulmonary tuberculosis was not more than half as fatal in London as it had been in the decade 1851–60, the earliest period for which trustworthy records exist. From an interesting diagram we learn that the male death-rate from pulmonary tuberculosis during the last half century has averaged 2·90 per 1000, or almost exactly 1 per 1000 above the female rate. Since the year 1880, however, the rate in both sexes has been constantly below the average, the female rate having apparently declined faster than the male.

Very interesting is the table showing the distribution of fatal pulmonary tuberculosis in the several metropolitan boroughs; it is unquestionably trustworthy, for in its construction care has been taken not only to refer institution deaths to the districts from which the patients originally came but to correct the death-rate of each borough for differences in the age and sex constitution of the living. From the last two columns in the table which show the mortality in the several boroughs as compared with that of the county of London, taken as 1000, we learn that 11 of the 29 boroughs had in 1901–05 an average mortality in excess of the county rate. In the year 1906 this was again the case, the rates in certain boroughs being above the county rates in some instances by from 20 to 70 per cent. In the years 1901–05 pulmonary tuberculosis was most fatal in Holborn, where the corrected rate was 2·58 per 1000, in Southwark 2·40, and in Bethnal Green 2·28 per 1000. As in previous years, Hampstead appears most favourably in the list, the rate there being only 0·82 per 1000, as compared with 1·57 in the county of London.

With respect to the influence of overcrowding in determining the relative fatality from pulmonary tuberculosis, there is a highly instructive table in the present volume, the like of which we should like to see included in the reports of medical officers of health outside the metropolis. This table shows that after making due allowance for age differences among the living, the mortality from pulmonary tuberculosis varies from a rate of 1·1 per 1000 in the least overcrowded sanitary areas to precisely double that rate in the areas where the overcrowding exceeds 27·5 per cent.

Elsewhere in the report comparison is instituted between the death-rate from pulmonary tuberculosis in the new model dwellings built by the County Council and that in London generally. In these dwellings at any rate, it may be presumed that the Council has taken adequate precautions against overcrowding. The figures now available are for one year only and relate to the mortality among not more than 21,000 tenants. Still, as far as they go, they are encouraging, for they indicate a reduction in the mortality from pulmonary tuberculosis of 14 per cent. as compared with that of other dwellers in the metropolis.

As regards statistics of mortality in different social strata of the population we have before commented on the advantage possessed by portions of Ireland over other parts of the United Kingdom. Sir Robert Matheson, the Registrar-General for Ireland, has, for many past years, published rates of mortality among different grades of the Irish people, and, as might be expected, these rates show remarkable disparity. Sir Shirley Murphy evidently appreciates the need for similar means of distinguishing between class and class in London; for, in the present report he presents a table showing the degree in which the dwellers in common lodging houses suffer from pulmonary tuberculosis, in contrast with other inhabitants of the metropolis. Since the year 1902 the administrative control of London common lodging houses has devolved on the County Council; and the medical officer of health has taken pains to inform himself as nearly as practicable concerning the effect of residence in such dwellings on the health of the lodgers. But in this attempt he is met by the difficulty that the mortality from separate diseases cannot satisfactorily be presented in terms of population, because of the extreme variations in the numbers living, from time to time; he therefore prefers to rely on the deaths from specified diseases in proportion to the deaths from all causes. From a table in which this alternative has been adopted we learn that of the total deaths of inmates of common lodging-houses, at ages 25–35 years, 54 per cent. were attributed to pulmonary tuberculosis, as against 40 per cent. in London generally; at ages 35–45 the percentages were 53 and 31 respectively; at ages 45–55 they were 48 and 23; and at ages 55–65 they were 31 and 12; whilst at ages above 65 the proportions were 11 per cent. in common lodging-houses as against 3 per cent. elsewhere in London.

As regards measures either in operation or in contemplation for limiting the prevalence of tuberculous disease, this report contains a section that will amply repay perusal. Abundant evidence is produced to show that there is a growing demand for really effectual methods of dealing with the disease over and above the ordinary expedients of isolation and disinfection usually adopted for the suppression of the acute infectious disorders. A system of voluntary notification of pulmonary tuberculosis obtains in many of the sanitary districts and this is generally followed by disinfection and by visits to the house, with advice as to precautions to be taken by the sufferer. In a few instances compulsory notification, with compulsory removal of advanced cases, has been advocated by medical officers of health. But on this point Sir Shirley Murphy insists, in our opinion, most justly, that the "latter view is more advanced than that which is actually held. It becomes therefore very necessary to examine the grounds for such a demand, which, if fully acted upon, would deprive of their liberty many thousands of persons in London." The current theories concerning infection on the one hand and heredity on the other which have been advanced to account for the incidence of pulmonary tuberculosis are ably discussed in the report. Reference is made to the opinions of Professor Karl Pearson who has specially studied this subject, utilising for this purpose the facts relating to 384 families in which cases of pulmonary tuberculosis had occurred. Professor Pearson found that the number of tuberculous married persons who had a tuberculous mate was not sufficiently great to require an appeal to infection in order to account for this number; but what he did find was that the condition which governed the liability to attack was heredity of the diathesis of pulmonary tuberculosis. "A theory of infection," he writes, "does not account for the facts. I am inclined to think that the risks run, especially under urban conditions, are, for tuberculosis as for a number of other infectious diseases, so great that the constitution or diathesis means almost everything for the individual whose life cannot be spent in self-protection; I feel fairly certain that for the artizan class the inheritance factor is far more important than the infection factor, because in a very large proportion of cases it does not lie in the power of the individual to maintain, in the stress of urban life, a wholly safe environment."

The passage in which Sir Shirley Murphy summarises his own conclusions on this important subject is worthy of blocks connected to an administrative building by open corridors. The blocks are one storey in height. The administrative department has a second storey containing bedrooms for nurses. The structure of the building is of corrugated iron and wood with a brick foundation; the inner walls are lined with "compo" boarding and are painted in distemper. The buildings are arranged one on each side and one behind the administrative block. All the wards face the south. The block behind the administrative department consists of two wards, each containing 12 beds. The total number of beds in the reception house is 62, and the cubic space allowed for each is 1500 cubic feet. The two other buildings have each one ward of 12 beds, one ward of six beds, and three single rooms. All the wards and rooms are provided with French windows and round the sides of each block there are verandahs. The beds can be wheeled from the wards to the verandahs with the greatest ease. Special provision has been made against fire. There are no fires in any of the wards and the heating is by water under a low pressure. Each ward has attached to it a bathroom and the necessary lavatory and water-closet accommodation. All the baths are so arranged that they can be used for the electrical treatment of the patients.

---

[1] The first notice of this report appeared in THE LANCET of Jan. 25th, 1908, p. 250.

Reference has been made to the upper storey of the administrative block in which nurses' rooms are situated. The lower storey consists of a reception room, bathroom, and examination room for newly admitted cases, a room well furnished with the latest electric therapeutic apparatus, medical officers' quarters, kitchen, scullery, and dining hall for the staff. The verandahs, which are on the south, east, and west sides of the wards, were purposely introduced. For several years previous to the erection of the reception house and sanatorium newly admitted and phthisical cases were kept as much as possible in the open air with manifest advantage. It was thought that the extensive use of verandahs would, in the prevalent climatic conditions, afford the greatest facility for carrying out the open-air treatment. In practice this has actually occurred. Since the opening of the reception house the freest use of open-air treatment has been employed, not only for the consumptive but for all the newly admitted cases.

1425 patients (737 males and 688 females) have been admitted since the reception house was opened. It has not been necessary, on account of inability to deal with them, to admit any of the patients to the main asylum or remove them shortly after admission from the reception house to the asylum. This is more remarkable in view of the fact that the reception house does not possess the means of restraint or seclusion. No day nurse has keys, and the ward doors are open all day. The windows are open night and day. All patients on admission are bathed and subsequently examined by the medical officer and by medical clerks who are senior students of medicine. The patients are kept in bed until their condition has been diagnosed. As a rule they are then removed to the respective buildings in the asylum which are most suited for their condition; thus, an infirm or senile case is sent to the infirmary of the main asylum; the phthisical patient is sent to the sanatorium; chronic cases with fairly good physical health are, in the first place, admitted to the wards of the main asylum where they are placed at occupations suited for their condition both of body and mind, and from there they are drafted to the farms where, if they do well, they may ultimately be boarded out in the country. In this way, from the point of classification, the reception house has many advantages. From the points of diagnosis and treatment the conditions are, in my mind, ideal. No patient is removed until a complete report of the physical and mental characteristics of his case is detailed in the case-books of the asylum and the course of care and treatment decided. Those patients who have a likelihood of early recovery are detained in the reception house until convalescence has been established. The number of patients who have been discharged recovered in this way is 216 (108 males and 108 females). There are three bedrooms in each of the southern blocks which are used in several ways. Any patient who is very excited and restless is placed in one of them with a nurse. The beneficial effects of this treatment have often been noticed. The rooms are also used for the moribund, and when available one is given as a privilege to a convalescent. These rooms are bright and attractive and so situated as to give the maximum amount of peace and quietness.

The nursing of the patients is mainly done by women. I have seen nothing to prevent the whole of the nursing being done by women, but I think this would be objectionable because we have not yet reached, nor shall we probably reach, the stage when all the patients in asylums will be nursed by women. I think it only fair to give male attendants, who have charge of working parties of patients, all facilities in the early stages of their asylum career for acquiring a sound knowledge of their profession, and adapting this knowledge to the advantage of the patients of whom they may ultimately be in charge at outdoor work. In the reception house I have followed the practice I have been accustomed to in the asylum hospitals for men. Two male attendants are regularly on day duty and two on night duty. The object I have in mind is thus acquired. Many objections to women nursing male patients, especially newly admitted male patients, have been urged. None of these will be found in practice, though experience has taught me to exercise the greatest care in the selection of nurses to male patients. This has reference solely to matters of staff discipline and does not affect primarily the welfare of the patients.

The following are some extracts from reports by His Majesty's Commissioners in Lunacy :—

By Dr. JOHN FRASER. *5th May, 1903.*—The reception house produced a most favourable impression. Its arrangements are devoid of any asylum features, being identical in every respect with those of a small general hospital. It is staffed by nurses and is under the charge of a trained hospital nurse. Every patient on admission is treated in this house and the length of residence there depends on the mental condition. The comfort, rest, skilful treatment, and good nursing which newly admitted patients receive in this house are most favourable to the early recovery of the curable and to the well-being of those who are incurable.

14th April, 1904.—The reception house and convalescent wards constitute a valuable and important advance in the treatment and classification of the patients.

By Dr. JOHN MACPHERSON. *15th Nov., 1904.*—The arrangements for the reception, nursing, and medical treatment of newly admitted cases in this asylum are now probably unsurpassed by those in any institution in this country. The facilities for the clinical investigation and the medical treatment of nervous diseases have been provided by the district board with unstinted liberality. It is right to add that Dr. Marr and his large staff of assistants are sedulously observing facts and carefully recording them, and that a mass of clinical material of great value is being gradually accumulated in the medical records of the asylum.

Woodilee Asylum, Lenzie.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8781 births and 5680 deaths were registered during the week ending Feb. 1st. The mean annual rate of mortality in these towns, which had been equal to 20·0 and 18·5 in the two preceding weeks, further declined to 18·2 in the week under notice. During the first five weeks of the current quarter the annual death-rate in these towns averaged 18·6 per 1000; the rate during the same period in London did not exceed 18·0. The lowest annual death-rates in the 76 towns last week were 7·3 in Hornsey, 7·6 in Smethwick, 8·7 in Northampton, and 9·7 in Burton-on-Trent; the rates in the other towns ranged upwards to 26·4 in Newport, 26·7 in Liverpool, 27·7 in Merthyr Tydfil, and 29·3 in Warrington. The rate in London last week did not exceed 17·2. The 5680 deaths registered in the 76 towns during the week under notice showed a further decline of 69 from the numbers returned in the two preceding weeks, and included 441 which were referred to the principal epidemic diseases, against 501 and 409 in the two previous weeks; of these, 190 resulted from whooping-cough, 83 from measles, 66 from diphtheria, 46 from diarrhœa, 35 from scarlet fever, 21 from "fever" (principally enteric), but not one from small-pox. The deaths from these epidemic diseases in the 76 towns were equal to an annual rate of 1·4 per 1000, the rate from the same diseases in London being 1·3. No death from any of these epidemic diseases was registered last week in Wolverhampton, Huddersfield, Wigan, Hornsey, or in six other smaller towns; the annual death-rates from these diseases ranged upwards, however, in the other towns to 3·1 in Bootle, in Bolton, and in Aston Manor, and 7·3 in Warrington. The fatal cases of whooping-cough in the 76 towns, which had been 164 and 154 in the two preceding weeks, further rose last week to 190; they caused annual death-rates equal to 2·3 per 1000 in Bootle and in South Shields, 2·5 in Aston Manor and in Bolton, and 5·1 in Warrington. The 83 deaths from measles showed a further decline from the numbers in the three previous the uncommonly large amount of sunshine which is one of the outstanding features of the climate of Algeciras and its neighbourhood. Taking the number of hours of sunshine per annum it averages 3000, or fully 1000 more than can be practically had at the very best English health resorts. All this is very important to visitors who have to leave their own countries to escape the rigours of the winter and who seek after warmth and sunshine. The best months for invalids are from October to June. The mean winter temperature is 55° F. in the shade. The air is dry and bracing and there are no sudden changes of temperature.

The English Hotel Reina Cristina, with its 22 acres of beautiful grounds outside the town, is an ideal winter place for delicate people and invalids able to move about. There are also the Hotel Anglo Hispano and smaller Spanish hotels and a few furnished houses and flats to be had for the season, but there is a lack of good accommodation for people of moderate means. All kinds of outdoor sports and amusements can be obtained in the neighbourhood, but except at Gibraltar one has to be satisfied with a quiet country life free from excitement.

From my experience of Algeciras since 1904 I am convinced that in many respects its climate is unequalled in Europe. I have noted marked improvement in cases of neuritis, insomnia, and other nerve troubles. Also gouty, cardiac, bronchial, and kidney cases as a rule are greatly benefited by residence in Algeciras. It is excellent also simply for a rest cure. Algeciras is not only a health resort but it is a convenient centre for visiting the most important and interesting places in Andalusia and Morocco, such as Ronda, Granada, Seville, and Cordoba on the one hand, and Tangier and Ceuta on the other. A splendid service of passenger steamers ply between it and Gibraltar daily (six miles). Gibraltar as a sea port if nothing more is one of the most convenient in Europe for visitors, as the liners of the P. and O., Orient, Norddeutscher Lloyd, White Star, Dominion, Cunard, and other great shipping companies call weekly, both on their outward and inward cruises, so that passengers can get to or from England and America on the one hand, and from and to Algiers, Marseilles, Genoa, Naples, and Egypt on the other, with the greatest ease and comfort. Visitors can either find their way to Algeciras overland by the express trains or by the P. and O. and other steamers in about four days from London and three days from Southampton.

Algeciras.

MEDICINE AND THE LAW.

Kissing the Book.

IN a recent appeal to the Divisional Court against a judgment delivered in the Brompton county court a new and curious point was raised with regard to the taking of the oath in the usual form by kissing a Testament. For this reason we refer again to a topic which has been so much discussed already in our columns and elsewhere. A medical man called as a witness had refused on sanitary grounds to kiss the Testament provided and had also objected to taking the oath in the Scottish form on the ground that he was a member of the Church of England. He had, however, produced a Testament on which he was willing to be sworn but the county-court judge had refused to allow him to avail himself of it, saying that he would not permit the oath to be taken upon any book except the one in ordinary use in the court. As a result the witness was not sworn and his evidence was lost to the party on whose behalf he had been called. Argument took place on the question whether the judge had decided wrongly in this matter and it was urged on behalf of the appellant that there was no suggestion that the Testament produced was not a perfect copy. This was in reply to a suggestion by Mr. Justice Phillimore that there were persons who would consider an oath less binding if it was taken upon a Testament not complete in every respect or in some other irregular manner. It was further argued by counsel that all that was necessary was that the judge should be satisfied that the Testament was one regarded by the witness as imparting a binding nature to his oath and that there was no legal obligation to use a volume provided by the court for the purpose and no other. Mr. Justice Phillimore is reported as having said that there could not be a new trial "because of a silly wrangle on the part of the doctor." It was his view that the question involved a matter of the discipline of the court, although the county court judge might have been wiser to admit the evidence, and the appeal was eventually dismissed. The objection raised to the Scottish form, which is to be administered without question to any who may prefer it, is not very easy to follow, but at the same time it seems highly unreasonable that a witness in the position of a medical practitioner who chooses to provide his own Testament should not be allowed to be sworn upon it. To suggest that he would be likely to commit perjury, solacing his conscience with the knowledge that the volume was defective and so was not a Testament, is little short of absurd.

Is a Master Liable for Medical Attendance on Servants?

The question of the liability of a master for medical attendance on his servants is one of considerable importance to the medical profession. A master is not bound to provide medical assistance for his servant but the obligation (if any) must arise from contract; nor will such a contract be implied simply because the servant is living under the master's roof, nor because the illness of the servant has arisen from an accident met with in the master's service. Thus where a servant who had been hired at the yearly wages of £3 10*s.* and victuals had his arm broken while driving his master's team, and was carried to his mother's house and attended by his master's surgeon, who was accidentally passing such mother's house at the time and was called in, it was held in Wennall *v.* Adney (3 B. & P. 247) that the surgeon could recover nothing from the master on an implied promise to pay for the attendance. Where such accidents take place the parish officers are bound to assist and the law will so far raise an implied contract against them as to enable any person who affords that immediate assistance which the necessity of the case usually requires to recover against them the amount of money expended. So in all cases where a servant falls ill and is unable to pay for necessary medical assistance the parish is bound to supply such assistance, although the servant may not have previously to his illness received or stood in need of parish relief. In Newly *v.* Wiltshire (2 Esp. 739) the defendant, a farmer, sent his wagon to Cambridge, and in returning a boy who had been sent with it fell from the shafts and broke his leg. The boy could not be removed out of the parish where the accident happened on account of the danger which it might occasion. The plaintiff was overseer of the parish where the accident happened and took the charge of getting the boy cured upon himself. It was necessary to amputate the leg and the overseer expended in and about the cure £32. Afterwards the boy served the remainder of the year with his master and the action was brought to recover from the defendant the expenses of the boy's cure. Lord Mansfield, Chief Justice, said: "I do not applaud the humanity of the master in this case; he does not inquire after his servant for six weeks after the accident; and when he does he passes on the other side. I think, in general, a master ought to maintain his servants and take care of them in sickness; but the question now is, What is the law? There is, in point of law, no action against the master to compel him to repay the parish for the cure of his servant; no authority whatsoever has been cited; and it seems to me that it cannot be. The parish is bound to take care of accidents." And Mr. Justice Heath, in Wennall *v.* Adney, said: "I am perfectly sure it is more for the advantage of servants that the legal claim for such assistances should be against the parish officers rather than against their masters, for the situation of many masters who are obliged to keep servants is not such as to enable them to afford sufficient assistance in cases of serious illness." Where, however, a father left his children under the care of servants, in a house at some distance from his own, and one of such servants was attacked by illness, which was caused by suckling one of the children, and called in a medical man who was not known to her master to attend her, and where the master's wife knew of such attendance and expressed no disapprobation, and, after this, the master sent his own surgeon to see such servant, it was held in Cooper *v.* Phillips (4 C. & P. 584) that the surgeon who had been originally called in by the servant could recover the amount of his bill from the master. A master is, however, bound to provide an apprentice with proper medicines and medical attendance (R. *v.* Smith, 8 C. & P. 153). It is not incident to the employment of a guard or the superintendent of a station of a railway to enter into a contract with a surgeon to attend a passenger injured by an accident

Indian Medical Service.

The result of the January examination was announced on Feb. 1st. There were 58 candidates, of whom 51 ultimately entered for the examination; of these, 48 qualified, the first 16 being admitted as lieutenants-on-probation, while one withdrew during the examination. The names of the successful candidates, with the marks obtained by each out of a possible maximum of 5100, are given below:—

Name.	Marks.	Name.	Marks.
W. E. Brierley	3988	F. R. Coppinger	3610
R. Knowles	3962	A. de C. C. Charles	3575
J. B. Lapsley	3796	J. W. Barnett...	3574
J. A. Shorten	3722	F. Stevenson	3554
R. B. S. Sewell	3680	S. H. West	3534

The Royal Navy List.[1]

This most excellent handbook has now been before the public for more than 30 years and each year demonstrates the care with which the book is compiled while everything is done to facilitate ready reference. Over 200 pages are devoted to the record of the war and meritorious service of officers both active and retired, and there is a complete list of ships of the Royal Navy with details relating to each ship. Under the heading of the "Naval Recorder" are an article on the current history of the Royal Navy, a list of the commissions and services of first- and second-class ships on the active list, a list of the fleets and squadrons in commission since 1878, and a chronological table of notable events from the year 1219 to the present time. A valuable feature of the Navy List is a bibliography of naval literature. The book should find a place in the library of everyone who is interested in our first line of defence.

PLEURAL EFFUSION AND ITS TREATMENT.

To the Editor of The Lancet.

Sir,—Sir James Barr affects to think that in agreeing to accept the term "pulmonary traction" and to substitute for my hypothetical case of fibroid phthisis with non-adherent pleuræ an actual one with adherent pleuræ I have made important admissions. This is a little ungallant of him, as these concessions were for the purpose of humouring Sir James Barr and with the full knowledge that they did not affect one way or the other the main issue between us, which is whether it is, or is not, necessary for the student of pulmonary physics to keep separate in his mind the conception of pulmonary tautness and that of pulmonary elasticity. I may at once say that after doing my best to get at Sir James Barr's meaning I do not find that he advances in his last letter a single valid argument against any of the statements made in my two previous letters. I shall once more endeavour to convince him that my contentions are as easy of proof as they are simple.

I, of course, recognise that the factor of resistance is an essential ingredient in our conception of pulmonary elasticity, that the lungs cannot be made to manifest their elasticity as regards a stretching force without being stretched, and that when they are stretched they pull on the visceral pleura and so exert traction on the circum-pulmonary structures; but it is not by virtue of their elasticity that the lungs exert this traction but by virtue of their tautness. It is quite true, as Sir James Barr insists, that the elasticity of the lungs enables them to retain their tautness and thus to exercise a continuous traction during the entire respiratory cycle, and I am ready to admit that this is a prime function of pulmonary elasticity, but we have no more right to say that the elasticity causes the traction than we have to say that the elasticity in the hangman's rope causes the death of the condemned man, or that the elasticity of the traces attached to a waggon causes the waggon to be pulled along.

Even Dr. D. W. Samways, for whose support, though qualified, I am grateful, fails, eminent physicist though he is, to make the necessary distinction between tautness and elasticity. "Consider," he writes, "the thorax and the respiratory muscles at rest. The lungs remain stretched; they support by their elastic recoil a certain fraction of atmospheric pressure to which the intrapleural space (if space it may be called) is not subjected in consequence. In that sense, as Sir James Barr states, 'there is a slight negative pressure in the pleuræ owing to the elasticity of the lungs.'" I submit that the negative pressure at this moment when the chest is kept fixed and when we may assume the intrapulmonary pressure to equal the extra-corporeal pressure is due to the tautness of the pulmonary tissue pure and simple and that the factor of "elasticity" or "elastic recoil" has nothing to do with it. Let us for argument's sake suppose the lungs in the case in question suddenly to be rendered perfectly non-elastic, their tautness, however, remaining unaltered. In such a case the negative pressure in the pleuræ produced by pulmonary traction would undergo no change. Is it not therefore evident that we must keep the idea of pulmonary tautness and that of pulmonary elasticity distinct? I shall presently show that this is not merely theoretically necessary but that in actual life it is possible to get a great increase in pulmonary tautness and a corresponding augmentation of pulmonary traction though pulmonary elasticity be considerably subnormal.

But first a word as to the factors which determine "pulmonary traction." They are two—pulmonary tautness and intrapulmonary air pressure. Pulmonary traction varies directly with the one and indirectly with the other. These two factors are not only distinct but may at one and the same time work in opposite directions. Thus if at the end of a deep inspiration when pulmonary tautness is at the maximum a powerful expiratory effort be made with closed glottis, the increment in intrapulmonary pressure thus produced more than obliterates the traction effect of pulmonary tautness, and consequently the lungs no longer exert traction upon, but actually press against, the surrounding parts. Contrariwise, if at the end of a deep expiration, when the pulmonary tissue is relaxed and the lungs cease to exercise traction, a powerful inspiratory effort be made with closed glottis, the greatly lowered intra-pulmonary pressure thus effected will give rise to considerable pulmonary traction.

Pulmonary tautness then plays an important part in determining pulmonary traction, the two tending to rise and fall together. Pulmonary tautness, however, bears no constant relation to pulmonary elasticity. I shall prove this proposition by reference to two diseases—hypertrophous emphysema and fibroid phthisis. Dr. Samways remarks on the fact that the elastic tissue of the lung "strangely chooses from birth onwards never to assume the unstretched conditions." This stretched condition of the pulmonary tissue is effected by the inspiratory muscles. As I have elsewhere pointed out, the inspiratory muscles are throughout life ever on the watch to maintain pulmonary tautness at a certain mean level, with the object of maintaining a constant suction or (as Sir James Barr prefers to call it) "traction" on the heart, and thus facilitating diastole; the inspiratory muscles, in fact, play a considerable part in effecting cardiac diastole—constitute, in fact, an important diastolic force. Now let us take a simple uncomplicated case of hypertrophous emphysema insidiously coming on, as it so frequently does, without any bronchitis or cough about middle life. The lungs gradually lose their elasticity much in the same way as the skin loses its elasticity. Suppose, now, the mean size of the chest to remain the same; it is obvious that the tautness of the lungs will fall below the normal and that there will be a corresponding fall in pulmonary traction. But the mean size of the chest does not remain the same. The ever-watchful inspiratory muscles, in obedience to the physiological necessity just referred to, cause an increase in mean thoracic capacity and thus tighten the pulmonary tissue up to the normal, much as the violinist is compelled from time to time to tighten up the strings of his instrument. And thus, as the pulmonary tissue loses in elasticity with every advancing month and year, the thorax is made to increase in size and for a long time *the tautness of the pulmonary tissue, in spite of steadily diminishing elasticity, is kept at the normal and with it the resulting pulmonary traction* until at length a point is reached at which the increase in the size of the thorax can no longer keep pace

PLEURAL EFFUSION AND ITS TREATMENT.

To the Editor of THE LANCET.

SIR,—Sir James Barr affects to think that in agreeing to accept the term "pulmonary traction" and to substitute for my hypothetical case of fibroid phthisis with non-adherent pleuræ an actual one with adherent pleuræ *I have made* important admissions. This is a little ungallant of him, as these concessions were for the purpose of humouring Sir James Barr and with the full knowledge that they did not affect one way or the other the main issue between us, which is whether it is, or is not, necessary for the student of pulmonary physics to keep separate in his mind the conception of pulmonary tautness and that of pulmonary elasticity. I may at once say that after doing my best to get at Sir James Barr's meaning I do not find that he advances in his last letter a single valid argument *against* any of the statements made in my two previous letters. I shall once more endeavour to convince him that my contentions are as easy of proof as they are simple.

I, of course, recognise that the factor of resistance is an essential ingredient *in our conception of* pulmonary elasticity, that the lungs cannot be made to manifest their elasticity as regards a stretching force without being *stretched*, and that when they are stretched they pull on the visceral pleura and so exert traction on the circum-pulmonary structures; but *it is not* by virtue of their elasticity that the lungs exert this traction but by virtue of their tautness. It is quite true, as Sir James Barr insists, that the elasticity of the lungs enables them to retain their tautness and thus to exercise a continuous traction during the entire respiratory cycle, and I am ready to admit that this is a prime function of pulmonary elasticity, but we have no more right to say that the elasticity causes the *traction* than we have to say that the elasticity in the hangman's rope causes the death of the condemned man, or that the elasticity of the traces attached to a waggon causes the waggon to be pulled along.

Even Dr. D. W. Samways, for whose support, though qualified, I am grateful, fails, eminent physicist though he is, to make the necessary distinction between tautness and elasticity. "Consider," he writes, "the thorax and the respiratory muscles at rest. The lungs remain stretched; they support by their elastic recoil a certain fraction of atmospheric pressure to which the intrapleural *space* (if *space* it *may* be called) is not subjected in consequence. In that sense, as Sir James Barr states, 'there is a slight negative pressure in the pleuræ owing to the elasticity of the lungs.'" I submit that the negative pressure at this moment when the chest is kept fixed and when we may assume the intrapulmonary pressure to equal the extra-corporeal pressure is due to the tautness of the pulmonary tissue pure and simple and that the factor of "elasticity" or "elastic recoil" has nothing to do with it. Let us for argument's sake *suppose the lungs in the case* in question suddenly to be rendered perfectly non-elastic, their tautness, however, remaining unaltered. In such a case the negative pressure in the pleuræ produced by pulmonary traction would undergo no change. Is it not therefore evident that we must keep the idea of pulmonary tautness and that of pulmonary elasticity distinct? I shall presently show that this is not merely theoretically necessary but that in actual life it is possible to get a great increase in pulmonary tautness and a corresponding augmentation of pulmonary *traction though* pulmonary *elasticity* be considerably subnormal.

But first a word as to the factors which determine "pulmonary traction." They are two—pulmonary tautness and intrapulmonary air pressure. Pulmonary traction varies directly with the one and indirectly with the other. These two factors are not only distinct but may at one and the same time work in opposite directions. Thus if at the *end of* a deep inspiration when pulmonary tautness is at the maximum a powerful expiratory effort be made with closed *glottis, the increment* in *intrapulmonary* pressure thus produced more than obliterates the traction effect of pulmonary tautness, and consequently the lungs no longer exert traction upon, but actually press against, the surrounding parts. Contrariwise, if at the end of a deep expiration, when the pulmonary tissue is relaxed and the lungs cease to exercise traction, a powerful inspiratory effort be made with closed glottis, the *greatly lowered intra-pulmonary pressure* thus effected will give rise to considerable pulmonary traction.

Pulmonary tautness then plays an important part in determining pulmonary traction, the two tending to rise and fall together. Pulmonary tautness, however, bears no constant relation to pulmonary elasticity. I shall prove this proposition by reference to two diseases—hypertrophous emphysema and fibroid phthisis. Dr. Samways remarks *on* the fact that the elastic tissue of the lung "strangely chooses from birth onwards never to assume the unstretched *conditions.*" *This stretched condition of* the pulmonary tissue is effected by the inspiratory muscles. As I have elsewhere pointed out, the inspiratory muscles are throughout life ever on the watch to maintain pulmonary tautness at a certain mean level, with the object of maintaining a constant suction or (as Sir James Barr prefers to call it) "traction" on the heart, and thus facilitating diastole; the *inspiratory muscles, in fact, play* a considerable part in effecting cardiac diastole—constitute, in fact, an important diastolic force. Now let us take a simple uncomplicated case of hypertrophous emphysema insidiously coming on, as it so frequently does, without any bronchitis *or cough about middle life.* The lungs gradually lose their elasticity much in the same way as the skin loses its elasticity. Suppose, now, the *mean size of the* chest to remain the same; it is obvious that the tautness of the lungs will fall below the normal and that there will be a corresponding fall in pulmonary traction. But the mean size of the chest does not remain the same. The ever-watchful inspiratory muscles, in obedience to the physiological necessity just referred *to*, cause an increase in mean thoracic capacity and *thus tighten* the pulmonary tissue up to the normal, much as the violinist is compelled from time to time to tighten up the strings of his instrument. And thus, as the pulmonary tissue loses in elasticity with every advancing month and year, the *thorax* is *made to* increase in size and for a long time *the tautness of the pulmonary tissue, in spite of steadily diminishing elasticity, is kept at the normal and with it the resulting pulmonary traction* until at length a point is reached at which the increase in the size of the thorax can no longer keep pace weeks; this disease, however, caused a death-rate of 1·3 in Southampton, 1·7 in Barrow-in-Furness, 1·8 in York, and 2·0 in Willesden. The 66 deaths referred to diphtheria, on the other hand, showed an increase upon recent weekly numbers, and included 24 in London, three in Liverpool, three in Manchester, three in Reading, and two in Bury; these deaths in the two last mentioned were equal to an annual rate of 1·9 and 1·8 per 1000 respectively. The 46 deaths attributed to diarrhœa showed a slight increase, whereas the fatal cases of scarlet fever had slightly declined; the highest rates from scarlet fever last week were 1·1 in St. Helens and 1·5 in Warrington. The 21 deaths referred to "fever" were fewer than in any recent week; four, however, occurred in Birmingham, four in Manchester, and two in Portsmouth. The number of scarlet fever patients under treatment in the Metropolitan Asylums and London Fever Hospitals, which had steadily declined in the eight preceding weeks from 5581 to 4044, had further fallen to 3913 on Feb. 1st; during the week ending on that day 405 new cases were admitted to these hospitals, against 469 and 360 in the two previous weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 499 and 455 in the two preceding weeks, further declined to 432 in the week under notice, but exceeded by 35 the corrected average number in the corresponding week of the five years 1903–07. The causes of 54, or 1·0 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Manchester, Leeds, West Ham, Bradford, Newcastle-on-Tyne, and in 45 smaller towns; and the causes of all but one of the 1584 deaths in London were duly certified. No fewer than ten of the causes of death in Birmingham, eight in Liverpool, four in South Shields, and three in Warrington were uncertified.

---

[1] The Royal Navy List and Naval Recorder, No. 121, January, 1908. Whitherby and Co., 326, High Holborn, London, W.C., and 4, Newman's-court, Cornhill, London, E.C.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 24·3 and 22·2 per 1000 in the two preceding weeks, was 22·3 in the week ending Feb. 1st, and exceeded by 4·1 the mean rate during the same week in the 76 English towns. Among the eight Scotch towns the death-rates ranged from 17·6 and 17·9 in Dundee and Aberdeen to 23·9 in Glasgow and 25·4 in Greenock. The 785 deaths in these eight towns exceeded by three the number in the previous week, and included 123 which were referred to the principal epidemic diseases, against 158 and 142 in the two preceding weeks; of these, 64 resulted from measles, 26 from whooping-cough, 11 from diarrhœa, eight from "fever," seven from scarlet fever, six from diphtheria, and one from small-pox. These 123 deaths were equal to an annual rate of 3·6 per 1000, which exceeded by no less than 2·1 the mean rate last week from the same diseases in the 76 English towns. The fatal cases of measles, which had been 92 and 81 in the two preceding weeks, further declined last week to 64, of which 54 occurred in Glasgow, three in Edinburgh, three in Aberdeen, and two in Greenock. The 26 deaths from whooping-cough exceeded the number in the previous week by one, and included 12 in Glasgow, six in Leith, three in Edinburgh, three in Greenock, and two in Perth. The 11 deaths attributed to diarrhœa, of which seven were returned in Glasgow, were fewer than in any recent week. Five of the seven fatal cases of scarlet fever occurred in Glasgow. The eight deaths referred to "fever" included six certified as cerebro-spinal meningitis, and two as enteric fever; four were returned in Glasgow, and three in Edinburgh. The six fatal cases of diphtheria included two in Glasgow and two in Dundee. The death from small-pox was registered in Leith. The deaths referred to diseases of the respiratory organs in these eight towns, which had been 205, 199, and 178 in the three preceding weeks, were 179 in the week under notice, and exceeded by 53 the number from the same diseases in the corresponding week of last year. The causes of 22, or 2·8 per cent., of the deaths in these towns last week were not certified or not stated; in the 76 English towns the proportion of these uncertified deaths last week did not exceed 1·0 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 31·2 and 29·5, per 1000 in the two preceding weeks, further declined to 25·5 in the week ending Feb. 1st. During the first five weeks of the current quarter the death-rate in the city averaged 27·5 per 1000; the rate during the same period did not exceed 18·0 in London and 19·1 in Edinburgh. The 193 deaths of Dublin residents registered last week showed a further decline of 30 from the high numbers in the two previous weeks, and included six which were referred to the principal epidemic diseases, against three and nine in the two preceding weeks; these six deaths included two from measles, two from whooping-cough, two from diarrhœa, but not one either from scarlet fever, diphtheria, "fever," or small-pox. These six deaths from epidemic diseases were equal to an annual rate of 0·8 per 1000, the death-rate from the same diseases last week being 1·3 in London and 1·9 in Edinburgh. The 193 deaths in the city last week from all causes included 34 of infants under one year of age and 70 of persons aged upwards of 60 years; the deaths of elderly persons were again exceptionally numerous. Five inquest cases and three deaths from violence were registered during the week, and 75, or 38·8 per cent., of the deaths occurred in public institutions. The causes of 12, or no less than 6·2 per cent., of the deaths in the city last week were not certified; in London the causes of all but one of the 1584 deaths were duly certified, while in Edinburgh 3·3 per cent. of the causes were uncertified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff Surgeons: W. R. Center to the *President*, additional, for three months' course at West London Hospital; W. H. Pope to the *Philomel*, on commissioning; H. P. Jones to the *Topaze*; M. P. Jones to the *Attentive*; E. S. Tuck to the *Foresight*, on recommissioning; C. C. Macmillan, D.S.O., to Malta Hospital; and R. F. Clark to the *Victory*. Surgeons: G. M. Eastment to the *Wildfire*; and C. J. O'Connell to the *Magnificent*.

Surgeon J. H. Lightfoot has been promoted to the rank of Staff Surgeon, with seniority of May 15th, 1907.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel George Coutts retires on retired pay (dated Feb. 5th, 1908).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 2nd Devonshire: George Douglas Kettlewell to be Surgeon-Lieutenant (dated Jan. 1st, 1908). 1st Glamorganshire: Surgeon-Lieutenant F. G. Thomas to be Surgeon-Captain (dated Jan. 9th, 1908).

Rifle: 1st Volunteer Battalion, The Sherwood Foresters (Nottinghamshire and Derbyshire Regiment): Surgeon-Captain A. B. Chambers resigns his commission (dated Dec. 20th, 1907).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Western Command: Manchester Companies: Honorary Lieutenant in the Army John William Smith (late Captain, Royal Army Medical Corps (Volunteers)), to be Captain (dated Nov. 21st, 1907). John O'Sullivan to be Lieutenant (dated Dec. 19th, 1907). Captain A. T. Lakin resigns his commission (dated Jan. 9th, 1908). Lieutenant W. E. Rothwell resigns his commission (dated Jan. 9th, 1908). Argyll and Sutherland Bearer Company: Lieutenant W. O. Murray to be Captain (dated Dec. 25th, 1907). Lancaster and Border Bearer Company: Surgeon-Captain Henry Dodgson, from the 3rd (Cumberland) Volunteer Battalion, The Border Regiment, to be Captain (dated Jan. 1st, 1908). Sussex and Kent Bearer Company: Lieutenant-Colonel and Honorary Colonel J. Turton is borne as supernumerary whilst holding the appointment of Brigade-Surgeon-Lieutenant-Colonel, Senior Medical Officer, Sussex and Kent Volunteer Infantry Brigade (dated Dec. 17th, 1907). Henry Arthur Clifton Harris to be Lieutenant (dated Dec. 17th, 1907).

DEATHS IN THE SERVICES.

On Jan. 25th, at the Royal Naval Hospital, Chatham, Staff Surgeon Harold Edgar Fryer, R.N. He joined the Royal Navy in 1897 as surgeon and was promoted to Staff Surgeon in 1905. The deceased, who was only 34 years of age, had been suffering from pulmonary tuberculosis.

and leave a vacuum between the two, and not only would the inspiratory muscles be incompetent to do this, but no force which can be imagined, not even one equal to 15,000,000 pounds or 15,000,000 tons to the square inch of chest surface, would be competent to do this, for in the process of expansion the thoracic walls or the lungs would rupture long before such a vacuum could be brought about. As a matter of fact, the inspiratory muscles are competent to expand the chest to its potential maximum, as may be observed in advanced cases of hypertrophous emphysema.

May I, Sir, in concluding this long letter venture to express the hope that this time the energy expended may not be entirely lost on Sir James Barr. Certain it is that I shall be more than content if it proves as profitable to him or to others as are the respiratory struggles of the unfortunate asthmatic profitable to the latter, convinced as I am that those struggles, blind and purposeless as they may appear to the casual observer, are yet wisely directed towards a useful end, and that but for them no patient could battle through a severe asthmatic paroxysm. Nature is not always such a fool as some seem to think.

I am, Sir, yours faithfully,

Wimpole-street, Feb. 2nd, 1908. Harry Campbell.

THE CAUSE OF THE PREVALENCE OF ADENOIDS.

To the Editor of The Lancet.

Sir,—I am glad Dr. J. Sim Wallace does not "put any importance on" his figures, for even more startling deductions might be made from them. As his five shut-window families have 26 children and his five open-window families but 19 he might have argued that closed windows at night increased the number of children born, and closed windows might be recommended to the President of the United States as a cure for race-suicide! But joking apart, I do not think Dr. Wallace will find that his theory is supported by facts. I think the explanation of his numbers, if one is needed, is that adenoid families see a lot of the doctor and where the doctor rules the windows are open at night. If adenoids are on the increase it cannot be due to open windows, for windows that really shut are of quite recent introduction. The old leaded glass always leaked and it is only since it was superseded that the bed-curtains and night-caps of our parents have been done away with. I am, Sir, yours faithfully,

O. Clayton Jones, M.B. Oxon.

Silverton, Exeter, Jan. 29th, 1908.

THE RESPONSIBILITY FOR THE ANÆSTHETIC.

To the Editor of The Lancet.

Sir,—It is to be hoped that Dr. Dudley W. Buxton's paper in The Lancet of Jan. 18th, p. 151, and your leading article thereon have been very carefully read not only by surgeons and anæsthetists but also by general practitioners. It happens far too commonly that a practitioner who calls in a surgeon to perform an operation—whatever the nature of this may be—suggests, and even requests, that he or his partner or assistant may give the anæsthetic, although there may be no adequate reason for not engaging a skilled anæsthetist. When such a request is made to a surgeon it is, of course, not easy for him to refuse, although he may have grave misgivings as to the result of his consent and although he may be well aware that the operator who permits a person of small experience to give an anæsthetic accepts a very serious responsibility.

I have no doubt such an arrangement is usually suggested in all good faith, for the majority of practitioners whom I have met do not seem to realise that for the proper conduction of a large proportion of the operations done at the present time special skill and experience are as needful in the anæsthetist as in the surgeon, and that the average practitioner cannot expect to be any more capable of replacing the one than the other. It is necessary not only to know the kind of anæsthetic best suited to the patient and to the operation but also to be well acquainted with the surgical procedure in order that pitfalls may be avoided. This is especially the case with operations on internal organs and above all with those (even "trivial" ones) on the upper air-passages, where safety and success can only be attained by a knowledge of the operator's methods and a perfect coöperation between him and the anæsthetist. So many instances have come to my knowledge where want of special experience in a self-constituted anæsthetist has led to inconvenience and even disaster that I venture to trouble you with this letter. I am, Sir, yours faithfully,

Jan. 25th, 1908. F.R.C.S.

THE PRESENT PROSPECTS OF THE MEDICAL PROFESSION.

To the Editor of The Lancet.

Sir,—The remarks of "Inspector-General" in your issue of Jan. 25th are worthy of the very greatest consideration, and call for more than ordinary passing comments in your correspondence columns. Indeed, a change of government in the whole attitude and conduct of modern professional manners is sadly needed. Everything is moving too quickly nowadays and this is not foreign to ourselves. There is a rush, a congestion, and a competition in our ranks which is decidedly tending to disorganise the enthusiasm and high aims of those who formerly filled the ranks of the profession. There is, in fact, disorder. That this is the outcome of education and general social changes is clear. But to stave off this wave of socialism in medicine needs a stronger bulwark than the lean-to wall of your valuable professional journal or any other medical publication of your standard.

Thus, Sir, my fragmentary remarks in The Lancet in support of "Inspector-General" may possibly only react proportionately as a grain of sand. But medicine is full of hope and, although slow in results, nevertheless a number of grains of sand may affect the whole problem before us—viz., the present, nay probably the future, prospects of the medical profession. We are apt to throw stones at glass windows and to blame others for a great deal that befalls the profession when, if we weighed the matter thoughtfully, perhaps we ourselves are sore. There are hundreds of men in the profession striving to aim at good deeds but they are baffled by those whose methods and practice are not pleasant to behold. If we despise the lay advertiser why should this not apply to ourselves, may I ask? Is not personal advertisement contrary to the ethics of the profession of medicine? Why, then, do gentlemen send open postcards and the like through the post seeking patients? Are there no censors in the profession? And, what is worse, how few of us have the courage of their opinions and perhaps are too shy to utter condemnation on personal advertisement? But is not the canker worm of self-advertisement a sign of stress—an ominous warning for the future of the profession for which some drastic measures will have to be devised sooner or later? It is impossible for a whole body of men to travel along a corduroy road for a length of time without several falling out of the ranks.

Again I will draw attention to another lapse in medicine among the present generation—namely, the using of proprietary drugs and other medicaments foreign to the order of the British Pharmacopœia. What has become of the good old pill may I ask? And if we do not actually practise empiricism do not we sail very close to the wind and encourage that class of the laity who deal in such things? Altogether, from the drug point of view, are we not getting very muddled?

As concerns our practice, there is no definite ruling as to what constitutes the exact duties of the general practitioner, because his need to earn a living wage encourages him to be Jack of all branches of the profession. Hence arises specialism, but truly there is more dabbling in the specialties of the profession by its members than is justified. And it is questionable whether this dabbling by the recently qualified is not indirectly an explanation of the oft-repeated public censure which the profession as a whole has to endure. In the army we see things are differently managed, for there is a stage of probation, then successive periods, including an examination, before the young man reaches the title of a colonel. And in general civil practice we ought to see something similar, so that a junior should not rank as high as his senior who has practised for many years. The licensing bodies might renew by fresh reception, at varying periods, an extension to practise, gradually weeding out those who by age, incompetency, or irregular practice rightly cease as practising members. Above all, before a candidate qualified to practise leaves the threshold of the licensing body, be it the Royal College of Physicians or the Royal College of Surgeons, there should not be the slightest doubt as to with the decrease in the elasticity of the lungs, with the result that pulmonary tautness and pulmonary traction sink below the normal. What better instance can I give of the need to distinguish between tautness and elasticity?

I now come to the case of fibroid phthisis. It is quite easy to prove that in this disease—in which all will admit there is an enormous diminution of elasticity—there may be a great increase in pulmonary tautness with a corresponding increase of pulmonary traction. Sir James Barr denies that the lungs are taut in fibroid phthisis. "Try and you will find that the fish does displace the water and the lungs are not taut and the intrathoracic pressure is not lowered." If the lungs are not taut, and if pulmonary traction is not increased, how are we to account for the "sinking in" of the upper part of the chest not infrequently met with in chronic phthisis as well as in the more acute forms of the disease? Instead, i.e., of the lungs exercising moderate traction on the upper part of the chest so that the inspiratory muscles have no difficulty in keeping that portion normally expanded, the lungs exercise a traction so great that the inspiratory muscles, strive how they may, are powerless to contend against it and the chest flattens in consequence.

It is needful to remember that pulmonary tautness is not necessarily equal throughout the entire extent of the lung. Under normal conditions, with non-adherent pleuræ and normal pulmonary texture, it tends to be. Thus when a purely abdominal breath is taken the lower part of the lungs expand first, but owing to the mobility of the lungs, rendered possible by the pleuræ, and owing to the uniform elasticity of the pulmonary tissue, the augmented tautness tends rapidly to diffuse itself throughout the entire lungs. When, however, the pleuræ are adherent, or when the structure of the lungs is profoundly modified as by the abundant deposit of fibrous tissue, one portion of the lung may be supernormally stretched while another part is only moderately taut. Suppose, for instance, that in its upper part the lung is highly fibrotic and the pleura is adherent, while in the lower parts there is emphysema, pulmonary tautness might be supernormal in the one part and subnormal in the other.

"Try and you will find that the intrathoracic pressure is not lowered." It is not clear whether Sir James Barr here means intrapulmonary or intrathoracic extrapulmonary pressure—two very different things. In another passage he refers to intrathoracic *or* intrapleural pressure, and presumably Sir James Barr is here referring to intrapleural pressure. Sir James Barr appears to assume that it is possible to measure pulmonary tautness and pulmonary traction by means of intrapulmonary pressure, but we have already seen that the two factors which determine pulmonary traction—pulmonary tautness and intrapulmonary pressure—may simultaneously operate in opposite directions. Sir James Barr not only denies that the lungs may be supernormally taut in fibroid phthisis but actually argues, or appears to argue, that pulmonary traction is necessarily lowered in this disease because the intrapulmonary pressure cannot in Müller's experiment be reduced to anything like the normal extent, say, only – 8 Hg mm., as against – 80 Hg mm. I freely admit that it may be possible to produce a higher degree of pulmonary traction in the normal individual by Müller's experiment than in the case of a patient suffering from fibroid phthisis. But people do not spend their lives in making Müller's experiment. Further, if Sir James insists upon dwelling upon the difference just referred to, I may point with equal force to the fact that in the contrary experiment of expiring with closed mouth and nares, the normal individual is capable of producing a very much higher intrapulmonary pressure than the patient with fibroid phthisis, and that therefore pulmonary traction is much more effectually obliterated and converted into pulmonary pressure in the former case than in the latter. Sir James's argument here cuts, in fact, both ways. What we have to do with, however, is not a temporary condition, voluntarily induced, but with habitual conditions, and, as a matter of fact, there is very little difference between the habitual mean intrapulmonary pressure of the normal individual and of the patient with fibroid phthisis. If, therefore, the average degree of pulmonary tautness is greater in the latter case than in the former the average degree of pulmonary traction must be greater.

Regarding my assertion that in cases of phthisis the mean size of the thorax may be increased, Sir James Barr says: "I always thought that fibroid tissue occupied less space than the portion of the lung which it replaced. I am afraid there is some confusion in Dr. Campbell's mind between fibroid tissue and the accompanying emphysema." Of course, fibroid tissue tends to occupy less space than the portion of lung which it replaces. For this reason, if the atrophied fibroid lungs are to increase in size and thus adapt themselves to the thoracic cavity, the mean size of which is constantly tending to be increased by the powerfully acting inspiratory muscles, something must give, and this giving involves not only the alveoli with the production of the emphysema to which Sir James refers, but also (what Sir James neglects to mention) the bronchi (causing bronchiectasis) and often also the tubercular cavities which tend to be pulled out by the taut lung tissue into spheroidal form; these yieldings manifestly all result from supernormal pulmonary tautness.

Sir James Barr asks why in fibroid phthisis my "heightened tautness of the lungs should allow the fingers to become bulbous"? the inference being (I presume) that by augmenting pulmonary traction it should facilitate, not impede, the circulation. The answer is surely obvious: in so far as the bulbous condition of the fingers in fibroid phthisis is due to obstructed circulation it results from the widespread destruction of the pulmonary blood-vessels. No amount of augmented traction on the heart could adequately compensate for this.

Commenting on my assertion that "comparatively non-elastic lungs, such as those seamed with scar-tissue, are capable of being rendered more taut, and thus of exerting more traction on circumjacent parts than normal, highly elastic lungs." Sir James Barr says: "This reasoning is that of the academician in his study and not that of the clinician who views facts and reasons therefrom. I shall now," he continues, "proceed to prick the bubble." This is his *modus operandi*: "Non-elastic fibroid lungs cannot be taut both in inspiration and expiration and therefore a constant negative pressure cannot thus be maintained." Quite true. Lungs wholly non-elastic could only become taut at the extreme limit of inspiration, and this to all intents and purposes means that with such lungs there would be no pulmonary traction, but, on the contrary, a positive pressure on the heart, and this would so interfere with the circulation, already sorely embarrassed by the block in the pulmonary circuit, that death would soon ensue. I admit that Sir James has pricked the bubble, but please note, Sir, that I am in no way responsible for the blowing of that poor bubble. Sir James himself is responsible for that, for it will be observed that in the passage he quotes from me I refer not to "non-elastic" but to "*comparatively* non-elastic" lungs—two very different things. While I believe it is possible for certain portions of the lung in fibroid phthisis (the apex, for instance) to be at one and the same time practically non-elastic, supernormally taut, and immobile, yet other portions must, if life is to continue, retain sufficient elasticity to remain taut during the ordinary respiratory movements.

To my contention that the enlargement in the mean size of the chest which may occur in fibroid phthisis is brought about by the inspiratory muscles, Sir James replied in his first letter that any stretching of the lungs that might occur was caused by the pressure of air within them and not by the inspiratory muscles. Referring to this I said in my last letter: "What has the average intrapulmonary air pressure got to do with the stretching of the lungs when the pleuræ are adherent? Manifestly nothing whatever," seeing that the pressure of the intrapulmonary air is counterbalanced by the extracorporeal air pressure. Dr. James Barr thus comments on this passage: "The question and answer coming from a physicist are really very funny. Does he not know that whether the lungs are adherent or not the thoracic parietes intervene between the external atmosphere and the lungs, and any force which expands the thorax beyond the expansile power of the lungs must exercise a force of 15 pounds to the square inch, and this the inspiratory muscles could not do over such a large surface as the chest though they tugged and pulled like Dr. Campbell at Cleopatra's Needle. The inspiratory muscles, like Dr. Campbell, often expend a lot of useless energy. How often do we grieve at the struggles of a poor asthmatic doing nothing?" Surely these remarks are beside the question. I nowhere made any mention of an "expansion of the thorax beyond the expansile power of the lungs," but simply referred to the moderate increase in the mean size of the chest which may sometimes be observed in cases of fibroid phthisis. Sir James's objections apply to such an expansion of the thorax as should separate the chest walls from the lungs with the steady accumulation of pilgrims as the fêtes approached. The telegram of Jan. 5th states that the rise in the number of deaths on that day was due to the arrival of infected caravans from Medina and Jeddah. On the 12th, the eve of the first day of Kurban Bairam, the pilgrims were *flocking out to Arafat* and *Mina*; the town of Mecca would be largely deserted, and the number of deaths from cholera there underwent a corresponding diminution. Then, after the fêtes, the pilgrims flowed back to the city, and there was an explosive rise in the curve of the outbreak, followed by a slight but steady fall. It is almost certain that the returns were very incomplete during the days that the fêtes lasted, when the pilgrims were in more or less constant movement, and distributed over a relatively large area. It may, therefore, be assumed that the true figures, could they have been ascertained, would have considerably exceeded those here given. The total number of cases reported from Mecca has been 4373, and that of deaths 3992 down to Jan. 20th.

In Medina the numbers have been less, as was to be anticipated, for, whereas all the pilgrims visit Mecca, only a certain proportion of them go to Medina; and, of these, perhaps the majority go there after, rather than before, the fêtes. It is unnecessary to quote the daily returns from Medina. They may be summarised as follows:—

Between Dec. 18th and Dec. 24th .... 78 cases ... 74 deaths.
" " 25th " Jan. 3rd ... 133 " ...113 "
" Jan. 4th " " 7th ... 73 " ... 32 "
" " 8th " " 15th ... 46 " ... 41 "

The returns from Medina have, however, been very incomplete; on many days the bulletin has been altogether missing.

In Yanbo 107 cases of cholera, with 69 deaths, were recorded between Dec. 20th and 24th; and 148 cases, with 91 deaths, between Dec. 25th and Jan. 3rd. Since the last-named date no news has been received of the course of the outbreak in Yanbo.

In Jeddah it will be recalled that two cases of the disease, both fatal, occurred on Dec. 26th and 29th respectively. Then, between Dec. 30th and Jan. 4th, there were 20 cases and 19 deaths; between Jan. 5th and 9th, 8 cases and 8 deaths; and between Jan. 10th and 19th, 4 cases with 3 deaths. Finally, the latest telegrams from Jeddah show that the pilgrims are now flowing back there from Mecca and bringing the infection with them. Thus, on the 19th it was reported that one case of cholera had occurred in a caravan arriving from Mecca; on the 20th 8 deaths from the disease were recorded there; and on the 21st there were 26 deaths and 3 cases isolated.

In the meantime the outbreak of cholera in the Abu-Saad lazaret (Jeddah) has diminished but has not come wholly to an end. It will be recalled that several ships arrived there from Yanbo with large numbers of hajjis suffering from the disease. Between Dec. 21st and 29th as many as 128 cases with 53 deaths occurred among these pilgrims. Between Dec. 30th and Jan. 4th there were 46 fresh cases and 36 deaths; between Jan. 5th and 9th 12 cases and 9 deaths; and between Jan. 10th and 18th 4 cases and 4 deaths. In addition, the French pilgrim ship from Sinope and Constantinople which was mentioned in my last letter arrived at the Abu-Saad lazaret on Jan. 3rd and reported that 19 deaths from cholera had occurred on board during the voyage. Possibly all these deaths were not due to cholera, as of three fatal cases from her landed at the Wells of Moses and originally reported as cases of cholera it has now been shown that only in 1 was death due to that disease, the others having died from pneumonia and pneumonia with dysentery respectively. However this may be, it appears that a further death from cholera occurred on Jan. 4th among this ship's pilgrims at Abu-Saad, and 7 more cases were landed from her on the 5th.

A pilgrimage so seriously contaminated with cholera as the present one offers an obvious and very real danger for the rest of the world; and for the next few weeks and months the sanitary defences of countries in close proximity to Arabia—and later possibly those of countries farther removed—will be put to a serious strain. On the present occasion a new factor, which did not exist during former epidemics, has to be taken into consideration by those responsible for the sanitary control of the dispersing pilgrims. This is the Hedjaz railway. A detailed scheme of measures for the sanitary defence of the line during the present Haj has been drawn up; and some, if not all, of these measures are already being executed. I hope to recur to this subject in greater detail in a later letter. The measures imposed by the Constantinople Board of Health on pilgrims returning from the Hedjaz by sea may be summarised as follows. Pilgrim ships coming to the Mediterranean will, after undergoing the measures prescribed by the Egyptian regulations at the lazaret of Tor, be subject to a further five days' quarantine and disinfection in one of the Turkish lazarets of Clazomene (Smyrna), Beirût, or Tripoli (Africa). In addition, those destined for Constantinople will be subject to a medical visit on passing the Dardanelles and again on arriving at Constantinople. Russian pilgrims are to be carried on ships exclusively reserved for their direct transport to Russian ports. Such ships will first do the regulation quarantine at Tor and will then be allowed to transit the Dardanelles and Bosphorus in quarantine. They will, however, be permitted to provision, under strict sanitary surveillance, at the Clazomene lazaret. Should cases of cholera occur on any of these ships they will be sent to the Clazomene lazaret for the necessary measures of quarantine and disinfection, after which they will still have to pass the Straits in quarantine.

As will have been gathered from earlier letters, the city of Constantinople has been menaced with a possible invasion of cholera from Russia through the latter part of the year just closed. Down to the last day of the year it was hoped, apparently with reason, that it would escape, in spite of the constant passage of pilgrim ships past its shores and in spite of the actual occurrence of one case among pilgrims in Stamboul in November.[2] This hope has now, unfortunately, been falsified. On Jan. 1st a case of disease presenting all the symptoms of cholera occurred in the Yenishehir quarter of the town. This is really a suburb of Pera. The patient died and the bacteriological evidence showed that death had in fact been due to cholera. This case has been followed at intervals by eight others, making nine in all; and eight out of the nine cases have ended in death. In every case the diagnosis of cholera based on the clinical history and appearances after death has been confirmed by the results of a bacteriological inquiry. The cases have been scattered over a large area, extending from the northern Bosphorus to the Marmora and including Pera, Stamboul, and both shores of the Bosphorus. Thus, in addition to the first case mentioned above, there have been two cases at Beicos, near the northern end of the Bosphorus on the Asiatic side; one at Rumeli Hissar, about half way up the Strait on the European side; two of boatmen in the Golden Horn; one in the Balata quarter of Stamboul (near the Golden Horn); one in a boatman at Haidar Pasha, opposite Stamboul, on the Asiatic shore of the Bosphorus and the terminus of the Bagdad-Railway; and, finally, one at Zeitun Bournou, on the Marmora shores of Stamboul. It is not known how these persons contracted the infection, nor has any connexion between the successive cases been traced. Passengers leaving Constantinople by sea or land are now subjected to a medical visit and disinfection on departure, and to a medical visit on arrival in another Turkish port. The weather in this city is at present cold, the thermometer varying between 0° and + 5° C. This may possibly explain the sporadic character of the outbreak up to the present and may countenance the hope that the infection will die out before the spring.

In Russia the epidemic has apparently completely come to an end. Since Dec. 18th (31st) no cases of the disease have been returned from any part of the Empire. The following figures complete those published in former letters:—

—	From Nov. 28th to *Dec. 4th.**		From Dec. 5th to 11th *		From Dec. 12th to 18th.*	
	Cases	Deaths	Cases	Deaths	Cases	Deaths

[2] THE LANCET, Jan. 4th, 1903, p. 52.

with the *decrease* in the elasticity of the lungs, with the result that pulmonary tautness and pulmonary traction sink below the normal. What better instance can I give of the *need to distinguish between tautness and elasticity?*

I now come to the case of fibroid phthisis. It is quite easy to prove that in this disease—in which all will admit there is an enormous diminution of elasticity—there may be a great increase in pulmonary tautness with a corresponding increase of pulmonary traction. Sir James Barr denies that the lungs are taut in fibroid phthisis. "Try and you will find that the fish does displace the water and the lungs are not taut and the intrathoracic pressure is not lowered." If the lungs are not taut, and if pulmonary traction is not increased, how are we to account for the "sinking in" of the upper part of the chest not infrequently met with in chronic phthisis as well as in the more acute forms of the disease? Instead, i.e., of the lungs exercising moderate traction on the upper part of the chest so that the inspiratory muscles have no difficulty in keeping that portion normally expanded, the lungs exercise a traction so great that the inspiratory muscles, strive how they may, are powerless to contend against it and the chest flattens in consequence.

It is needful to remember that pulmonary tautness is not necessarily equal throughout the entire extent of the lung. Under normal conditions, with non-adherent pleuræ and normal pulmonary texture, it tends to be. Thus when a purely abdominal breath is taken the lower part of the lungs expand first, but owing to the mobility of the lungs, rendered possible by the pleuræ, and owing to the uniform elasticity of the pulmonary tissue, the *augmented tautness* tends rapidly to diffuse itself throughout the entire lungs. When, however, the pleuræ are adherent, or when the structure of the lungs is profoundly modified as by the abundant deposit of fibrous tissue, one portion of the lung may be supernormally stretched while another part is only moderately taut. Suppose, for instance, that in its upper part the lung is highly fibrotic and the pleura is adherent, while in the lower parts there is emphysema, pulmonary tautness might be supernormal in the one part and subnormal in the other.

"Try and you will find that the intrathoracic pressure is not lowered." It is not clear whether Sir James Barr here means intrapulmonary or intrathoracic extrapulmonary pressure—two very different things. In another passage he refers to intrathoracic *or* intrapleural pressure, and presumably Sir James Barr is here referring to intrapleural pressure. Sir James Barr appears to assume that it is possible to measure pulmonary tautness and pulmonary traction by means of intrapulmonary pressure, but we have already seen that the two factors which determine pulmonary traction—pulmonary tautness *and* intrapulmonary pressure—may simultaneously operate *in opposite directions*. Sir James Barr not only denies that the lungs may be supernormally taut in fibroid phthisis but actually argues, or appears to argue, that pulmonary *traction* is necessarily lowered in this disease because the intrapulmonary pressure cannot in Müller's experiment be reduced to anything like the normal extent, say, only – 8 Hg mm., as against – 80 Hg mm. I freely admit that it may be possible to *produce* a higher degree of pulmonary traction in the normal individual by Müller's experiment than in the case of a patient suffering from fibroid phthisis. But people do not spend their lives in making Müller's experiment. Further, if Sir James insists upon dwelling upon the difference just referred to, I may point with equal force to the fact that in the contrary experiment of expiring with closed mouth and nares, the normal individual is capable of *producing* a very much higher intrapulmonary pressure than the patient with fibroid phthisis, and that therefore pulmonary traction is much more effectually obliterated and converted into pulmonary pressure in the former case than in the latter. Sir James's argument here cuts, in fact, both ways. What we have to do with, however, is not a temporary condition, voluntarily induced, but with habitual conditions, and, as a matter of fact, there is very little difference between the habitual mean intrapulmonary pressure of the normal individual and of the patient with fibroid phthisis. If, therefore, the average degree of pulmonary tautness is greater in the latter case than in the former the average degree of pulmonary traction must be greater.

Regarding my assertion that in cases of phthisis the mean size of the thorax may be increased, Sir James Barr says: "I always thought that fibroid tissue occupied less space than the portion of the lung which it replaced. I am afraid there is some confusion in Dr. Campbell's mind between fibroid tissue and the accompanying emphysema." Of course, fibroid tissue tends to occupy less space than the portion of lung which it replaces. For this reason, if the atrophied fibroid lungs are to increase in size and thus adapt themselves to the thoracic cavity, the mean size of which is constantly tending to be increased by the powerfully acting inspiratory muscles, something must give, and this giving involves not only the alveoli with the production of the emphysema to which Sir James refers, but also (what Sir James neglects to mention) the bronchi (causing bronchiectasis) and often also the tubercular cavities which tend to be pulled out by the taut lung tissue into spheroidal form; these yieldings manifestly all result from supernormal pulmonary tautness.

Sir James Barr asks why in fibroid phthisis my "heightened tautness of the lungs should allow the fingers to become bulbous"? the inference being (I presume) that by augmenting pulmonary traction it should facilitate, not impede, the circulation. The answer is surely obvious: in so far as the bulbous condition of the fingers in fibroid phthisis is due to obstructed circulation it results from the widespread destruction of the pulmonary blood-vessels. No amount of augmented traction on the heart could adequately compensate for this.

Commenting on my assertion that "comparatively non-elastic lungs, such as those seamed with scar-tissue, are capable of being rendered more taut, and thus of exerting more traction on circumjacent parts than normal, highly elastic lungs," Sir James Barr says: "This reasoning is that of the academician in his study and not that of the clinician who views facts and reasons therefrom. I shall now," he continues, "proceed to prick the bubble." This is his *modus operandi*: "Non-elastic fibroid lungs cannot be taut both in inspiration and expiration and therefore a constant negative pressure cannot thus be maintained." Quite true. Lungs wholly *non-elastic* could only become taut at the extreme limit of inspiration, and this to all intents and purposes means that with *such* lungs there would be no pulmonary traction, but, on the contrary, a positive pressure on the heart, and this would so interfere with the circulation, already sorely *embarrassed by* the block in the pulmonary circuit, that death would soon ensue. I admit that Sir James has pricked the bubble, but please note, Sir, that I am in no way *responsible for the* blowing of that poor bubble. Sir James himself is responsible for that, for it will be observed that in the passage he quotes from me I refer not to "non-elastic" but to "*comparatively* non-elastic" lungs—two very different things. While I believe it is possible for certain portions of the lung in fibroid phthisis (the apex, for instance) to be at one and the same time practically non-elastic, supernormally taut, and immobile, yet other portions must, if life is to continue, retain sufficient elasticity to remain taut *during* the ordinary respiratory movements.

To my contention that the enlargement in the mean size of the chest which may occur in *fibroid phthisis* is brought about by the inspiratory muscles, Sir James replied in his first letter that any stretching of the lungs that might occur was caused by the pressure of air within them and not by the inspiratory muscles. Referring to this I said in my last letter: "What has the average intrapulmonary air pressure got to do with the stretching of the lungs when the pleuræ are adherent? Manifestly nothing whatever," seeing that the pressure of the intrapulmonary air is counterbalanced by the extracorporeal air pressure. Dr. James Barr thus comments on this passage: "The question and answer coming from a physicist are really very funny. Does he *not know that* whether the lungs are adherent or not the thoracic parietes intervene between the external atmosphere and the lungs, and any force which expands the thorax beyond the expansile power of the lungs must exercise a force of 15 pounds to the square inch, and this the inspiratory muscles could not do over such a large surface as the chest though they tugged and pulled like Dr. Campbell at Cleopatra's Needle. The inspiratory muscles, like Dr. Campbell, often expend a lot of useless energy. How often do we grieve at the struggles of a poor asthmatic doing nothing?" Surely these remarks are beside the question. I nowhere made any mention of an "expansion of the thorax beyond the expansile power of the lungs," but simply referred to the moderate increase in the mean size of the chest which may sometimes be observed in cases of fibroid phthisis. Sir James's objections *apply to such* an expansion of the thorax as should separate the chest walls from the lungs preserve this drain in case the place where these cattle-men now sleep should on some occasion be required for cattle. Then the drain would be useful. In the meanwhile the only concession made is the introduction of a few planks so that manure still continues to pass to and fro inside the men's cabin but it is boarded over. There are steam-pipes all round and these are much needed in the winter for heating the cabins but they also help to increase the odour of the manure. Obviously the manure from the cattle should not be allowed to penetrate the cabin where men sleep. The quarters for the cattle-men are more extensive than the seamen's quarters and there are many bunks, but if anything there is even less provision for ventilation. The seamen occupy a cabin where there is no order, no principle, no sign of any scientific effort whatsoever to procure ventilation, though there are several pipes leading down to their cabin. One of the pipe ventilators had evidently been closed up. This will inevitably happen, for it does not suffice that there should be a pipe to admit the air; there must also be means so to regulate this inlet that it shall not cause an injurious or unpleasant draught. Then in the seamen's quarters there was the chain pipe down which the anchor chain rattles and makes a great noise, rendering sleep difficult. It is true that all hands are generally on deck when the anchor is weighed.

Some of the closets were locked and it is curious how often the keys are mislaid when a ship is unexpectedly visited. However, I succeeded in seeing a trough closet, with three seats and no privacy. A pipe communicating with the donkey-engine discharges water that would clear out the bottom of the trough, but the splashings on the side of the trough would not be effected by this occasional flush. They are supposed to be scrubbed away by a brush, but it is doubtful if this is done, and then if it is done what becomes of the brush? This brush, impregnated with fæcal matter, might be a source of danger if any of the persons using the closet were carriers of typhoid or cholera bacilli. That the clearing out of a closet with three seats should depend on hand labour and a brush properly and frequently applied to the sides of a trough is a most rudimentary and dangerous arrangement. To find such an insanitary closet on a ship shows how little attention is given to these matters. The washing accommodation also was absolutely insufficient. In "the glory hole," a term which derisively designates the stewards' quarters, I found near the entrance a small wooden shelf. In this a round hole had been cut just the right size to hold a wooden bucket. This receptacle was half full of water in which, to judge from appearances, more than one person had already washed. It was necessary to go out on deck to pour the dirty water away and to get a clean supply. The stewards are crowded together in a very small space and are left to do the best that they can. If they wash at all it is greatly to their credit considering the few facilities afforded. Nevertheless, some passengers are carried on this ship, and it is high time that the travelling public should insist that those who wait upon them must have all the necessary convenience to keep themselves clean.

On another and smaller ship which does not carry cattle but only cargo and passengers I likewise found very miserable conditions among the firemen and sailors. Over one bunk in a very small and unventilated cabin there passed the soil-pipe from a closet which was on the deck above. The pipe came across the angle from the deck just above this upper berth and the side of the ship. During the last voyage this pipe burst and the soil fell on the fireman's bed. Never before have I seen a soil-pipe above and within a few inches of a bed. Instead of removing this or at least putting in a new and sound pipe, it had only been roughly mended with soldering and a patch. The same accident may therefore occur again. Though I found no ventilator in the firemen's quarters there was an air-pipe coming down into the seamen's quarters. The cabin was loftier than usual but very crowded and there was not floor room enough for two or three sailors to dress at one and the same time. Another ship of the same type offered somewhat similar disadvantages. The firemen's quarters had just been scrubbed and washed out and still did not smell sweet. I noticed here that the doors of the small food lockers had in many instances been wrenched off. These food lockers are a source of trouble and of danger especially in respect to the rats which they attract. In any case they ought not to be in the sleeping compartment. If there is a mess room there might be food lockers but these should not be allowed in the overcrowded sleeping cabins. Now that the law insists on 120 instead of 72 cubic feet per head this will be more easily managed; but a ship was pointed out to me which, though built quite recently, had only allowed 72 cubic feet for the crew and therefore there was no room for washing, yet the men have to eat and to sleep in their small cabins. As for washing, an iron bucket was provided and it was used either on deck or in the stoke-hole. This, however, was a Channel boat, whereas the other ships I have described are all engaged for ocean traffic and make prolonged journeys.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Quarterly Report of the Medical Officer of Health.

THE medical officer's report upon the last quarter of 1907 may on the whole be looked upon as indicating a fairly satisfactory condition of the health of the city during the latter part of last year. The death-rate was 16·1 per 1000, a little worse than in the corresponding quarter of 1906, and the birth-rate unfortunately was extremely low—26·6 per 1000, which is a slightly lower rate than in the last quarter of the previous year. The most unsatisfactory features of the quarter were the continued prevalence of scarlet fever and measles. The cases of scarlet fever reported numbered 904, or almost double the number recorded in the same period of 1906, and the deaths caused by the disease were more than double those of the same period last year—that is, 39, as contrasted with 18; yet even this unsatisfactory condition is better than that which has prevailed in some of the past years. The cases of diphtheria, although far too prevalent, were not so numerous as in the last quarter of 1906, and the deaths which resulted from it were comparatively few, the death-rate being only 9·1 per cent. There were only 70 cases of typhoid fever, a new record for the quarter, and the history of some of the cases pointed so strongly to infection by means of mussels that an inquiry into the matter has been commenced but as yet no results have been published.

The Cost of Medical Inspection of School Children.

There is a growing sense of irritation in this district against the expense which the new Act is going to throw on the ratepayers, more particularly in densely populated areas where the cost will fall most heavily. It is pointed out that increased administrative expenditure will be necessitated, but the increased administrative expenditure does not strengthen a claim for a special grant for educational purposes, for the Board of Education has decided not to allow special grants for expenditure on administrative purposes which exceed the produce of a penny rate. It is becoming more and more obvious that administrative expenses must increase if the new rules and laws are to be carried out, and in these circumstances the opinion is becoming more and more plainly expressed that if Parliament and Government departments make rules and regulations which must cause increased expenditure and if that expenditure is to be incurred for national purposes then the ruling authorities should at the same time make arrangements to provide a considerable proportion of the necessary money.

The Milk-supply of the City and the Midland Farmers' Association.

At the recent annual meeting of the Midland Farmers' Association attention was directed to Dr. J. Robertson's report that 14 per cent. of the milk sent into Birmingham was contaminated with tubercle bacilli. The association recommended all its members to exercise great care in the examination of their cows, particularly as regards the udders, and advised them to take steps at once to remedy any abnormal conditions. The executive committee expressed its willingness to coöperate with the health committee of the city in every possible way. In moving the adoption of the report Lord Harrowby expressed the belief that the Bill dealing with the question of milk-supply which is to be brought before the House of Commons contains no provision for the payment of compensation for animals slaughtered for the public good, and a motion was carried stating the conviction of the association that legislation requiring the compulsory slaughtering of infected cattle should be associated with provision for proper compensation.

what are his duties to himself and his professional brethren. This should be empanelled in a thoroughly bound document with the stamp of the College detailing their methods and manners of practice and all matters likely to lead to controversial dispute in the future of the recipient.

We have no regular scale of fees, but the most important point for all thoughtful men is the spirit of trade-unionism which has been discussed so much in the medical journals. Once and for all let us at once knock such nonsense on the head. Until there is a revolution or a break up of the empire no such practice can be adopted in the care of the sick and wounded. How can we regulate hours of labour in war, and the practice of medicine is war against disease. There is also another spirit which is equally increasing in the rising generation which affects the nobility of our calling. As is the case of the servants of the Church, poverty to a great extent must befall the rank and file of medicine. There is only room for a certain number of bishops and of physicians and surgeons in ordinary and the rest must be satisfied with their lot and be content with a life of love for their fellow creatures. I do not know of any calling in life in which a love of medicine with a private income could be better fulfilled and do at the same time much signal service to the medical profession. Parents of the well-to-do might well consider this and put their sons into the profession of medicine instead of other callings. How cowardly seems the way in which we sometimes neglect our right when we stoop to the power of money.

I would remark that the rise and fall of our profession or of a nation will always be dependent upon its leaders, and I would emphasise the great importance of this leadership and example from those who are officers in the great army of medicine and surgery. I mean our teachers and professors at the schools for medicine and surgery, the authorities at the Royal Colleges, and all to whom the student of physic looks for his education and guidance. If I have confined myself to a particular groove of thought perhaps some other members of the profession will take a different line and give assistance in this difficult question of the present prospects of the medical profession. Perhaps he will confine himself more strictly to what may seem to be the text, but I hope he will at least remind the great leaders of medicine and surgery of their enormous ethical responsibilities. For such leaders may stave off the effects of the wave of discontent in the medical profession.

I am, Sir, yours faithfully,
VIRTUTEM SEQUOR.

Jan. 25th, 1908.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Jan. 25th "Inspector-General" mentions several reasons for the alleged present serious financial condition of many of the general practitioners of this country. "Inspector-General," however, gives no remedy. I do not think we have far to seek to find the cause and therefore the cure. The cause, to my mind, is the ignorance or lethargy, or both, of a large number of the general practitioners. On H.R.H. the Prince of Wales's return from his colonial tour, when speaking at the Guildhall, his message to Great Britain was to "wake up." The same message, to my mind, might with advantage be taken to heart *and acted upon* by a vast number of the general practitioners scattered through our land.

"Inspector-General" mentions "quackery" as one cause—granted; and undoubtedly legislation ought to come to our aid in this respect, not mainly to protect us, however, but to protect the public. Your correspondent mentions "preventive medicine," but not as a cause; it certainly is not a cause, for, granted a proper knowledge of preventive medicine, our incomes would be quite as large from the exercise of that humane branch as from the treatment of disease, and certainly with greater satisfaction to ourselves. "Inspector-General" gives two other reasons for the present serious financial condition of many members of our profession—viz., (1) that railways have brought the rural districts "into touch with towns where patients can consult some medical man renowned for special knowledge of their ailments"; and (2) "the abuse of medical charities." The first of these causes he says is "entirely non-medical"—I disagree. The second cause undoubtedly exists. I maintain that both are the fault of the general practitioners to a very large extent. If the mass of general practitioners of this country knew their work well they would treat the cases themselves and not send them to "specialists," nor would their patients go to "specialists."

The medical student before he leaves his hospital ought to hold at least one appointment in every branch of his profession, so that when he goes into practice he is able to remove tonsils, adenoids, turbinates, polypi, and other nasal obstructions; to treat diseases of the throat, nose, ear, &c.; to correct errors of refraction and deal with astigmatism; to properly treat displacements of the uterus, be able to curette the uterine cavity, amputate the cervix, &c., and so on through all the thousand-and-one minor operations. His knowledge, however, should not cease there, but nowadays with surgery so simplified by aseptic methods he ought to be able to do abdominal surgery and other major operations.

Where does the "specialist" come in? In his proper place, to diagnose really obscure cases, to operate on those cases which this or that general practitioner is not justified in doing because he is unable to get sufficient practice in this or that particular operation. If the general practitioner knew his work, as I maintain he ought to know it, the wealth of the "specialists" would to a large extent be distributed over the medical community, the number of "specialists" would be reduced, and the medical profession would once more be flourishing. It is, I think, forgotten by many that each patient sent by them to a "specialist" means the loss to them, only too frequently, not only of that patient but of all that patient's friends who have, or think they have, any disease affecting that particular region of the body.

I say again, let the general practitioners of this country "wake up"; let those who do not know their work properly, learn it; and those who do, awake from their lethargy and do the work themselves. Personally, I have been in general practice many years and now am half a general practitioner and half a consultant, although not being on the staff of a hospital I am aware that some would deny me the right of calling myself a consultant at all—but in that case they must call me a general practitioner who is consulted frequently by his fellow practitioners. How have I acted in the past? Whenever necessary to consult a "specialist" I have gone with my patient, have kept my eyes open, and any operations I did not know how to do I very soon learnt the way and in the future did them myself as long as I felt justified by my knowledge to do so. To my mind *there* lies the principal remedy, and if the general practitioners will only exercise it we should soon hear less of these financial difficulties.

I am, Sir, yours faithfully,
HALF-AND-HALF.

London, Jan. 25th, 1908.

THE SPREAD OF CHOLERA IN THE NEAR EAST.

(FROM THE BRITISH DELEGATE ON THE CONSTANTINOPLE BOARD OF HEALTH.)

As reported in my last letter[1] this year's pilgrimage to Mecca and Medina is very seriously infected with cholera. From Mecca the following daily returns have been received since the beginning of January (these figures are in continuation of those published in the letter just referred to):—

Jan.	1st	52	deaths	15	cases isolated.
,,	2nd	52	,,	4	,,
,,	3rd	56	,,	14	,,
,,	4th	67	,,	17	,,
,,	5th	86	,,	12	,,
,,	6th	98	,,	20	,,
,,	7th	127	,,	46	,,
,,	8th	185	,,	48	,,
,,	9th	177	,,	42	,,
,,	10th	241	,,	27	,,
,,	11th	257	,,	6	,,
,,	12th*	121	,,	—	
,,	13th	62	,,	—	
,,	14th	16†	,,	—	
,,	15th	31‡	,,	—	
,,	16th	143§	,,	—	
,,	17th	486	,,	18‖	cases isolated.
,,	18th	394	,,	—	
,,	19th	350	,,	—	
,,	20th	246	,,	—	

* On this day the pilgrims left Mecca for Arafat and Mina. † At Mina 82 deaths. ‡ At Mina 201 deaths. § At Mina 195 deaths. ‖ The pilgrims had now returned to Mecca.

The above figures are interesting. Up to Jan. 11th there was a steady rise in the number of deaths, corresponding considerably more value than any two courses of lectures they were likely to get in one week" is a matter which need not be considered here. The voting showed pretty clearly the feeling of the meeting, 19 votes being for the motion and 4 against. A certain amount of satisfaction at this result in favour of preparation for defence may perhaps be allowed, even in these days of cosmopolitanism.

Feb. 4th.

WALES AND WESTERN COUNTIES NOTES.

(From our own Correspondents.)

Health Report of Cardiganshire.

Although the insanitary conditions which prevail in certain parts of Cardiganshire have been the subject of investigation by the medical inspectors of the Local Government Board upon various occasions the county council has never taken any steps in the direction of remedying those conditions. It is possible that individual members of the council may excuse this inaction on the plea of ignorance of the circumstances; such excuse will, however, no longer avail, for there has recently been issued a summary of the annual reports for 1906 of the district medical officers of health which has been compiled by Mr. Evan Evans, D.P.H. The very forcible manner in which attention is drawn in the summary to the prevalence of pulmonary tuberculosis in the county ought to awaken the council to a sense of its responsibilities. During 1906 the death-rate from this disease in the whole county was 2·6 per 1000, compared with 1·6 in Merionethshire and 0·8 in Monmouthshire. In Aberystwith rural district the death-rate was as high as 4·3 per 1000 and in the Cardigan rural district it was 3·2 per 1000. Mr. Evans considers that the migration of the healthiest and most vigorous individuals to other districts and the return home of those infected elsewhere is a considerable factor in this high death-rate. Other causes are insanitary dwellings and an insufficient dietary, for from nearly all districts comes the same tale—closed windows at night and staple dietary of bread and butter. There does not appear to be any form of disinfection of the dwellings of patients suffering from pulmonary tuberculosis either before or after a death. Now that the attention of the county council has been drawn to the very unenviable position occupied by Cardiganshire with regard to the prevalence of this disease the claims of the Allt-y-mynydd Sanatorium ought to be responded to generously. It is difficult to believe that the chief administrative body, which includes among its members four medical practitioners, will remain inactive after the disclosures which have now been made public.

Medical Inspection of Schools in Cardiff.

Upon the recommendation of the medical officer of health, Dr. E. Walford, a subcommittee has advised the Cardiff education committee to appoint two medical assistants, each at a salary of £250 per annum, to devote the whole of their time to the services of the committee, acting under the direction of the medical officer of health who, as chief medical officer to the education authority, will organise, supervise, and assist in the work of medical inspection, report upon the results of the inspections, and be generally responsible to the committee for all the medical and sanitary matters connected with the public elementary schools in the town. Two women inspectors, each of whom is a trained nurse and a certificated inspector of nuisances, have been employed for some time past in the health department of the Cardiff corporation and Dr. Walford suggests that they could assist in filling in the schedules connected with each medical examination and without attempting anything like medical treatment could be most useful in visiting the houses of defective children and bringing home to the parents a full sense of their responsibilities with regard to their children. Dr. Walford thinks that in most cases tactful advice and useful counsel are most urgently required and that generally the parents of defective children would be ready and willing to take steps themselves to bring about the physical improvement of their children if they only knew what steps were necessary. He further pointed out to the committee that without any direct medical treatment on the part of the education authority much physical improvement might be effected by a greater attention to the sanitation of the school buildings and by the improvement in the environment of the scholar which would result from the more frequent visits of a medical man.

Tuberculosis in Herefordshire.

For several years past a branch of the National Association for the Prevention of Consumption and Other Forms of Tuberculosis has been doing good work in Herefordshire. Popular lectures have been given in different parts of the county and in other ways there has been disseminated information as to the means by which tuberculous disease may be prevented. The death-rate from pulmonary tuberculosis in the county, as a whole, is not high, for many years past having averaged 1·0 per 1000, but in some parishes the rate is as high as 2·5 per 1000, and it has been estimated that there are at the present time about 500 persons suffering from this disease in the county. At the last meeting of the county council the general purposes committee was instructed to report as to the practicability of establishing a sanatorium for incipient cases of tuberculosis. The suggestion appears to be that a sanatorium should be established by the various boards of guardians in the county and that they should pay to a central fund the cost of maintaining pauper patients in the sanatorium.

Breathing Apparatus in Coal Mines.

The colliery owners of Monmouthshire and South Wales have recently been considering a scheme for establishing central rescue stations in various parts of these coalfields. It has been suggested that there should be 13 such stations in the Rhondda valleys, the Merthyr and Aberdare valleys, Garw and Ogmore valleys in Glamorgan and in the eastern and western valleys in Monmouthshire. The estimated cost of each station is £2000 and £500 for the equipment together with £500 annually for the maintenance. The particular apparatus to be used has not been decided upon, for it is hoped that inventors of different forms will demonstrate their usefulness to a committee of the coalowners which has been formed for the purpose of giving practical effect to the project.

Typhus Fever in Monmouthshire.

When reporting upon a fatal case of typhus fever which had occurred in the urban district of Ebbw Vale in Monmouthshire, Mr. J. W. Davies, the medical officer of health, stated that in his opinion it was due to overcrowding and filthy surroundings. There was only one bedroom in the house occupied by the patient, the other occupants being a man and his wife and three children. It appears that the house concerned, together with those adjoining, had already been condemned as uninhabitable and the tenants were living in them rent free until other dwellings could be found.

Feb. 4th.

SCOTLAND.

(From our own Correspondents.)

Friction at Ruchill Fever Hospital, Glasgow.

Considerable disquietude has been aroused in the public mind in Glasgow owing to the evidences of serious friction which have become apparent recently among the staff at Ruchill Hospital. 14 months ago a new matron was appointed to the hospital and it seems that subsequently to that the nurses, of whom there are about 150 employed in the institution, made complaints, alleging that the hospital was understaffed and that the nurses were overworked. These complaints were embodied in a letter addressed on Sept. 30th by the five assistants forming the resident medical staff to the physician-superintendent of the hospital. The main allegations put forward in the letter were: (1) an insufficient number of nurses in certain wards; (2) an insufficient number of sisters, or charge nurses: (3) inexperienced nurses in charge of wards; and (4) inefficient ambulance administration. The superintendent is thereupon alleged to have informed them that in the domestic and nursing department of the hospital he had no jurisdiction over the matron. A letter of complaint was then addressed to the town clerk on Nov. 27th. Soon thereafter a notice was posted at the hospital intimating that an inquiry would be held by the sub-committee of the hospital which stated that it would receive any statement which a sister or nurse wished to make regarding the conduct of the hospital. Thereupon 105 of the nursing staff wrote offering to testify and a number of these were examined. Before Christmas the inquiry was

The total number of cases of cholera registered in the Russian Empire since the beginning of the epidemic down to Dec. 18th (31st) was 12,109 and that of deaths 5800.

Constantinople, Jan. 23rd.

SANITATION AT SEA.

THE VENTILATION AND DRAINAGE OF SOME LIVERPOOL PASSENGER SHIPS.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

THE newest developments in shipbuilding may inspire the hope that real progress will be accomplished in securing sanitation at sea; nevertheless, the fact remains that there is still much to be done. Undoubtedly the rivalry in running great and luxurious liners is a force that makes for sanitary improvements. It is now very generally acknowledged that special machinery must be employed to propel the necessary amount of air into a ship; therefore the newer and best ships have machinery for this purpose. This is a great step forward. There now remain the regulation of such supply and its even distribution over all parts of the ship without, however, causing injurious draughts. Having seen on the *Mauretania* and the *Lusitania* the latest efforts that have been made in this direction, I visited the White Star liner *Cedric*, which is not a new boat nor can it be considered an old boat. Again, it is not one of the more recent and extravagantly luxurious ships, while, on the other hand, it is a very large and comfortable vessel. It was in the early morning of Nov. 21st last that I went on board this ship while still in dock at Liverpool, though she sailed that afternoon for New York. My first experience was to assist at the examination of the crew and steerage passengers by the Board of Trade medical inspectors. The crew marched past in Indian file as their names were called out, for they had already been placed in line and in order along the promenade deck. Then followed some 350 steerage passengers. An interpreter helped the medical officer to ask questions. But as all these persons had previously been carefully examined by the ship's surgeon this was more a formal matter and only doubtful looking passengers were stopped and questioned anew. Some of the emigrants were rather rough in manner and appearance. They were taught their first lesson of ship's discipline by being made to take off their hats and to remove their cigarettes from their mouths when passing before the inspectors. But the manner in which this lesson was conveyed was at times as rough as the behaviour it was intended to correct. There was more trouble with the women. The Board of Trade instruction is that nothing must be taken on board that might be the cause of hurt or injury. Consequently, a dead set was made against hatpins. These sharp points protruding from the sides of women's hats are undoubtedly dangerous on a crowded deck, particularly when, as the ship rolls, passengers stumble up against one another. The examining medical officer explained that recently in a Liverpool omnibus a lady moved her head in such a manner that she drove her hatpin into a gentleman's eye. The lady thereupon had a fit of hysterics in the omnibus but this did not restore the wounded gentleman's sight. Consequently all the women had to remove their hatpins before they were allowed to proceed, but as these dangerous implements were not confiscated I do not see what is to prevent their using them again once the ship is out of port. The stewards will have a hard time of it if they are going to watch all these women and see that they never use their hatpins again during the whole voyage. Still, it is undoubtedly dangerous to wear hats from which protrude long and sharp pins when the sea is rough and it is impossible to walk straight and steadily. Some curious incidents occur during these examinations. Thus one woman was kept back to be examined more thoroughly because she persisted in saying that she did not know the age of her own child. Perhaps she was afraid of being charged a higher fare, though this had nothing whatsoever to do with the medical officer. All he could do was to insist on the child showing the vaccination marks. The chief thing was the eyes. Four passengers had been refused by the ship's surgeon and the Board of Trade medical inspector again re-examined the eyes of several passengers. Some looked very wretched specimens of humanity, but there was no organic defect, so they were allowed to pass.

The *Cedric* is a very large ship of 21,000 tons and could carry 1835 third-class passengers. It possesses in all ten steam and six electrical ventilating fans but also relies largely on natural ventilation. There are numerous mushroom cowl ventilators in the sheltered parts of the promenade deck. How far these work satisfactorily I had but few opportunities of ascertaining. One thing I may venture to say. The lavatories are badly situated; indeed, they are in so unsuitable a position that it is absolutely necessary to employ mechanical force to prevent a nuisance arising. They are just in the very centre of the ship, as far away from the sides or from natural ventilation as it is possible to place them. Now there is in this a distinct advantage. The Criterion was, I believe, the first theatre in London to be ventilated scientifically and this simply because being built entirely underground there could be no natural ventilation whatsoever. In the lavatories of the *Cedric* there are air shafts or trunks along the ceiling with openings over each closet seat and the suction, mechanically produced, is so strong that a piece of paper will be held against the wire netting by the force of the outrushing air current. In the third-class dining-room I also found the suction within the ventilating trunks strong enough to hold paper fast against the apertures for drawing out the air. The system here is to draw away the air, leaving it to find its way in by the accident of doors and portholes. The electric fans employed are of the "sirocco" type and they are very powerful. They are reserved for the passenger part of the ship. But the very word "sirocco" suggests the principal difficulty. Something like a sirocco might be useful for a blast furnace but no one would desire to have a sirocco in his cabin. Perhaps when applied for suction only it may not cause much inconvenience but if the air is blown into the cabins with great force the ventilators will be closed. Thus though there were many air shafts or trunks travelling along the ceiling, notably in the sleeping compartment of the steerage, the currents of air coming through the apertures which I examined seemed to me much too strong for anyone to sit or to lie down near them. There is great need of a more systematic means for delivering the air so as to avoid cutting draughts. In the hospital I could not find any mechanical ventilation, though it is more needed there than elsewhere. There was what is called a torpedo ventilator communicating with the very badly situated hospital closet. This is a sort of cowl which catches the air as the ship moves along and is of little or no use when the ship is not moving. But it should be in the open air, whereas in this case it was between decks and near the descent to the hold. There were, of course, portholes, and some of them have an air inlet but this is natural ventilation. Undoubtedly, the lavatories are the best ventilated part of the ship and the hospital should have been treated in the same manner. In the smoke room there was a double dome. Some of the glass panes of the inner dome were removed and replaced by ornamental fretwork. As a suction is produced between the outer and inner dome the air is drawn away through the fretwork. In a word, it seemed to me that though the *Cedric* possesses a considerable amount of mechanical power this is not utilised in a systematic manner. The means are there but their application is defective. Too much is left to accident, there is no well-thought-out organised method. But probably much about the same thing could be said of almost every ship afloat.

The Board of Trade insists that there shall be means of ventilation, but what indication is there as to how these are to be applied? If the result is far from perfect even on palatial liners what happens on ships of more modest pretensions? While in Liverpool I had the opportunity of visiting a few of the latter kind of ships belonging to other and to different companies. This experience was neither pleasant nor encouraging. One was a big cattle ship which was to sail in about 24 hours. The filth that still remained on board was so abundant that I failed to see how the ship could possibly be cleaned in time. Of course, this was due to the cattle which had been on board, and though these had been landed some time ago it does not seem to me that the decks had been properly scoured out. In dark corners there were still accumulations of nondescript filth and refuse. Where some of the cattle-men sleep there is a gutter running along the side of the ship. Liquid manure and water travels and with the pitching of the ship sometimes rushes along this gutter. It passes under some of the bunks occupied by cattle-men. It used to be uncovered and caused a very bad smell. The only reason for not doing away with it altogether is the desire to officer from office unless for good and sufficient reasons. It was then moved and seconded—

> That in view of the resolution carried at last meeting with reference to the medical officer and without prejudice to the pleas of the council as to the regularity and validity of his appointment the council resolve to dispense with the services of Dr. Brown on three months' notice, and the clerk be, and hereby is, instructed to give Dr. Brown, under reservation of the said pleas, three months' notice of dismissal; and further that the council direct the clerk to advertise the vacancy in terms of the regulations.

This motion was carried. The chairman thereupon handed in a protest stating that the dismissal of Dr. Brown constituted a breach of the council's contract with him. The protest further stated that, on behalf of Mr. A. H. Farquharson of Invercauld, and on his own behalf, he protested against the parish assessments being employed in expenditure connected with any action which might be taken as a result of this breach of contract, and held those who voted for the motion as liable to recoup him in any loss or damage which he might sustain. Two other members of the council also handed in protests. Dr. Brown laid on the table a protest which was read by the chairman. In this he declined to accept notice of dismissal from the council on the ground that he held his appointment from Feb. 23rd, 1907, and that the council had failed to give him the six weeks' notice which was declared by the Local Government Board to be necessary. He also declined to take delivery of any letter containing such notice of dismissal.

Feb. 3rd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The late Lord Kelvin.

Lord Kelvin was certainly one of the most distinguished men to whom Ireland has ever given birth and it is fitting that a statue should be raised to him in his native city of Belfast. A sum of nearly £1000 has been subscribed for the purpose as the result of a public meeting.

The Royal College of Surgeons in Ireland.

The annual dinner of the College took place on Feb. 1st at the College, Sir Henry R. Swanzy, the President, being in the chair. The toast of "The College" was proposed by Dr. J. Magee Finny, President of the Royal Academy of Medicine of Ireland, and was responded to by Sir Henry Swanzy who took legitimate pride in pointing out the many improvements that had recently been made in the medical school attached to the College.

Death of Professor Antony Roche.

The death is announced of Mr. Antony Roche, professor of medical jurisprudence in the Catholic University and examiner at the Royal University of Ireland. Professor Roche took great interest in sanitary science and made many interesting communications to THE LANCET.

Sanatorium for the County of Cork.

In the year 1902 the various public boards of the county of Cork agreed to submit to a rate of 1*d.* in the £ for the erection and maintenance of a sanatorium for consumptives. Since then the project has undergone many vicissitudes. The conjoint board first selected a site at Marsytown, near Macroom, but the Local Government Board refused to approve of it on the grounds that it was unsuitable for the purpose. The next site proposed was Myshall, but as a river from which some of the water-supply comes for Cork would bound the proposed grounds of the sanatorium the Cork town council appeared by counsel at the Local Government Board inquiry and offered strenuous opposition to the adoption of the site. Again the Local Government Board entered a *non possumus.* Then Mr. Brazier-Creagh, a member of the conjoint board, offered a free site at Streamhill, near Doneraile, and his colleagues, mindful of their previous experiences, decided on casting as far as possible on the shoulders of the Local Government Board the onus of selecting a site and accordingly requested that body to send two of its inspectors to visit the lands offered by Mr. Brazier-Creagh. The Local Government Board acceded to the request and a week ago an inquiry was held by Dr. E. C. Bigger and Mr. Cowen, C.E., the two inspectors who had visited the proposed site and had apparently approved of it. It was not considered necessary to produce any medical evidence in favour of the site but it was soon found that a number of people residing in the neighbourhood of Streamhill were opposed to the project, and it was urged that the expectorations of the patients could find their way into an adjoining river and spread the disease amongst the inhabitants and their cattle. Lord Castletown and Mr. Harold-Barry of Ballyvonare, landlords who have extensive holdings near Streamhill, also objected on the ground that their properties would be injured. An engineer gave evidence that the soil on which it is proposed to build the sanatorium is peaty and retentive, and Mr. Harold-Barry said that it is bog over which he shot snipe. Professor H. Corby stated that the fact of it being a bog would at once condemn it. He also expressed the opinion that the sanatorium treatment is so comparatively valueless that it is a pity a large sum of the ratepayers' money should be expended on the erection of a sanatorium in any part of the county. Some witnesses were then examined who gave evidence in favour of the site and the inquiry terminated. It is believed that the recent report of the Local Government Board of England on the sanatorium treatment of consumption will influence the Cork conjoint board in abandoning the project of erecting a sanatorium for the county.

Poor-law Administration in Belfast.

At a meeting of the Belfast board of guardians on Jan. 14th it was reported by the clerk that the estimates for the year ending March 31st, 1908, showed an increase of £3959, due to the large number of inmates, especially infirmary patients, there being an increase of nearly 400 patients. There was an increase of 200 in those requiring medical treatment and an increase of 72 in children. In clothing the average weekly cost had gone up from 6½*d.* per week to 9*d.* Then outdoor relief would reach £1670 for the current half-year and a total of £3601 for the year, and taking the increase to go on progressively it would be almost £4000 and a rate of 1*s.* 1*d.* in the pound would be needed in the forthcoming year. It must be candidly admitted that such figures raise among many the suspicion that the Poor-law system is not what it should be in Belfast. Why should pauperism increase in Belfast where for the past three or four years trade has been brisk? It would seem as if among some of the poor the spirit of independence, which formerly at least prevailed and which prevented them accepting assistance from the workhouse unless sheer want drove them into it, is gone. Then the workhouse system really encourages pauperism owing to the fact that the inmates are now better housed, better fed, and better cared for than a large proportion of the poorer ratepayers. Such a state of affairs is really a direct incentive to many lazy, idle people to join the pauper ranks and it imposes an almost unbearable burden on those who are just on the border-line of pauperism. Again, the increase in the infirmary patients is one of those weak points in the Poor-laws that require to be remedied, as it is surely wrong that struggling ratepayers should have to pay for the treatment of those who might reasonably be called upon to discharge their own liabilities. An increase in the cost of clothing—almost to one-third—is very extraordinary, and considering the industrial conditions of Belfast an outdoor bill of £3600 is really preposterous and contrary to the recommendations of Mr. Agnew, the Local Government Board inspector. In the Belfast workhouse there is the population of a small town (4028 inmates were in it a week ago). How many of the lazy, idle men and women in this institution do anything (as occurs in Switzerland and other continental countries) for their upkeep? The ratepayers of Belfast are beginning to see that the guardians must exercise much more discrimination in the administration of relief.

The Consumption Dispensary in Belfast.

At a meeting of the city council of Belfast in committee held on Jan. 20th it was decided after some discussion to agree to an arrangement by which the Forster-green Hospital for Consumption will undertake to open a dispensary in the city or, in other words, an out-patient department, on the understanding that the corporation takes ten beds in addition to the 25 already provided and pays at the rate of £1 15*s.* a week for each additional bed, with the proviso that in case any of the said ten beds should be vacant the corporation is to be given credit for each such bed at the rate of 15*s.* per week for the time such vacancy shall continue, the agreement to be for one year with the option of renewing it at the end of that period. This new development will cost, it is said, almost £3000 per annum.

Feb. 4th.

St. John Ambulance Association.

The report presented at the annual meeting of the Birmingham centre of the St. John Ambulance Association shows that the work of the centre continues at a high level. 24 classes were held during the year and most satisfactory examination results were secured. It was stated that the appeal made for funds for the Birmingham corps of the brigade had not met with a satisfactory response, and further support is needed to enable the brigade to attain its full development. In proposing a vote of thanks to the Lord Mayor, who presided at the meeting, Dr. T. Nelson, the chief surgeon of the brigade, pointed out that new headquarters would be required, for those at present held have to be given up during the year, and he expressed the hope that provision might be made in the new municipal buildings. If Dr. Nelson's hope is realised the brigade will be fortunate, but no doubt whether in the municipal buildings or elsewhere suitable headquarters will be found.

The Analyst's Report.

The analyst's report is always interesting reading for it gives us a general idea of the possible purity of the food we consume. Apparently during the last quarter of 1907 our milk-supply was less tampered with than during the same period of the previous year, and the cases of addition of poisonous preservatives were both very few and comparatively unimportant. Butter also, so far as the samples taken were concerned, showed less evidence of adulteration than in the same quarter of 1906. We may therefore congratulate ourselves that during the latter part of 1907 our food was a little more pure than usual and that may be looked upon as some compensation for its increased cost.

The late Sir William Cook.

By the death of Sir William Cook Birmingham is deprived of a man who took the greatest interest in, and gave freely of his services to, everything which appertained to the good health of the city. He was chairman of the health committee for the long period of 34 years. He was closely associated with, and took an active part in, every important movement for the sanitary reform of the city during that time and we have to thank his skill, foresight, and energy for many of the advantages which we enjoy to-day. One of the last efforts which he made for health purposes was that by which he induced the council to acquire Salterby Grange for a sanatorium, and, in the opinion of many people, he was the only man who could have induced the council to take the step at the time when the motion was brought forward. From 1880 till his death he was chairman of the Hospital Saturday Fund and he had the pleasure of seeing the annual income of the Fund gradually increase till last year it attained to the amount of £20,000, a sum upon which he had set his heart. He was a governor of the General Hospital and a supporter of the New Lying-in Charity. He worked hard for both institutions; indeed, he was a man who will always be honoured as one who gave his best work for the good of his fellow citizens.

Feb. 4th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Anthrax in the Market.

A CASE brought before the stipendiary magistrate on Jan. 29th shows how necessary it is that skilled inspection of food should be carried out by those who are qualified and alert. Two quarters of beef were exposed for sale in the meat market on Dec. 12th last. The chief veterinary inspector said it was "rough-looking" and took a sample. Microscopical examination, confirmed by others, showed that it was a case of anthrax. There does not seem to have been any attempt at concealment in this case, for when the inspector said that he should have to seize the whole of it the butcher told him he had sold the other half but kept this for the inspector to see. He also showed a letter from the person who had sent the carcass saying that the heifer had been accidentally hanged and was not bled till an hour after it happened. "But run no risk; have it inspected before exposing. I expect it is all right." This looks as if the sender's suspicions were excited. Happily the portions already sold were recovered before any had been used for food. The defendant had been in business for 30 years and was a past-president of the Manchester and Salford Butchers' Association; he had "an unblemished business reputation," so that he had every motive for not attempting any concealment of the facts. He had, however, to pay a fine of £10 and costs, and the magistrate said, "if he had been of opinion that the defendant sold the meat knowing it to be affected with anthrax he should have been obliged to send him to prison." This may seem to be rather a hard case for the butcher but the food-supply must be carefully guarded.

Useful and Unobtrusive.

Though our charities are no doubt often abused, yet those who know most as to the condition of the patients in the Manchester hospitals acknowledge that on the whole they are as to means in a state of poverty, and from that point of view worthy of help. One of the most useful ways of affording help is to give them suitable garments for use in hospital or on leaving. The Manchester Hospital Work Society is an association that year by year distributes garments, made by the associates themselves, to the poor sick in the hospitals. It has been correctly described as a society for work and not for collecting money, and this description was justified by the statements made at the annual meeting presided over by the Lady Mayoress on Jan. 29th. But like most other organisations, its prosperity ebbs and flows, and this last year the tide of its success was low. Dr. A. M. Edge said that fewer garments had been received for distribution, far short of two garments per bed which is aimed at. New hospitals and hospital enlargements are being built, so that the outlook is serious as they mean more patients. There is one point named in the report of the committee which will be appreciated by those who deplore the deaths from burning so often occurring where flannelette is worn. The committee pleaded for the use of flannel and not flannelette in making bed jackets. Dr. W. Walter read the financial statement which showed the year's income as £103 and the working expenses as £19 14*s*. The lady associates had contributed 2228 garments, while the funds only allowed of 448 being purchased. This special charity is one that appeals more particularly to the active benevolence of women and should be more successful than it is. The Lady Mayoress, who must be acknowledged to speak with authority on such a subject, considered that "two garments a year were really a very small contribution from one woman," and she seemed to think that fancy work was more attractive than plain sewing, but ventured to predict that the day of the former would go by and good plain needlework come to the front. The value of the work was testified to by Mr. Andrew Boutflower and other medical men. Surely there are many ladies in the district who would gladly join in this work if it were brought to their notice. *Apropos* of the mention of flannelette, on Jan. 29th the city coroner held inquests on four children in different parts of Manchester who had died from burning. The usual accounts were given—the absence of the mother for a few minutes, no fireguards, and playing with matches. The coroner said that "it was most heartrending to have to hold inquests on so many little children."

Convocation of the University of Manchester.

A meeting of the Convocation was held on Jan. 29th, when Professor R. B. Wild was unanimously elected chairman of Convocation. Dr. George Ashton, Captain R.A.M.C. (Volunteers), moved:—

> That in the opinion of Convocation it is the duty of the Manchester University authorities to give every support to Mr. Haldane's Territorial Army scheme.

The meeting, he said, was not asked to discuss the scheme politically or to consider its merits or demerits. It had passed through Parliament and would come into force on April 1st next. In East Lancashire the county association was expected to provide a division—i.e., about 19,600 men. Dr. Ashton thought that the University had not in the past shown the interest in the Volunteer movement which he could have wished. "There were about 1100 students and only 125 volunteers," and among the teaching staff—about 200—only three held commissions, and he wanted to see more of the students and more of the teaching staff engaged in the scheme. One gentleman, as an American "outlander," thought that all the students would be the better for "military drill and discipline," and there is no doubt whatever that he gave utterance to a truth. Whether his further view that "for a large number of students military drill would be of

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The Italian Red Cross: A School for Female Helps.

THE otherwise admirably equipped Red Cross of Italy is admittedly defective in one important adjunct to its efficiency—an adjunct long possessed by the sister societies of the Red Cross in other countries—that of female helps. These helps are recruited from the class of ladies of good social position, whose education, already productive of refinement in manner and demeanour, has been specially enhanced by training in the *métier* of nurse. During the sanguinary Russo-Japanese war the lady-helps (*dame infermiere*) of both belligerents gave memorable proof of their good offices not only on the battlefield but on other occasions involving disaster—explosion or similar accidents in camp or quarters—inseparable from military operations. Of these offices, on the Russian side, the Italian representative Count Camperio was an assiduous witness and the account which he gave of them in a lecture delivered last year in Rome profoundly impressed the many interested in Red Cross organisation. The regional subcommittee of the "Croce Rossa Italiana" at once utilised the interest thus evoked by putting itself in communication with the central committee, and its initiative has now fructified in a "school" specially equipped for the training of lady-helps on the lines of the Russian and Japanese organisations—a school which will be officially opened to-day in the buildings of the military hospital on the Caelian Hill. Her Majesty Queen Elena is the patroness and at her instance an appeal has been addressed to the ladies of Rome to give the institution all the encouragement in their power. The response has already been more than gratifying and the present year will witness the start of a corps of "infermiere voluntarie" (volunteer lady-helps) which will place Italy on a level with her sisters in the one branch of Red Cross equipment in which she has hitherto been defective. The appeal—a lengthy but none the less impressive document—sets forth the programme of special instruction to be given on the Thursdays and Sundays of successive weeks throughout five months of the year between the hours of 3 and 6 P.M. The subjects taught will be essentially practical in their tenour, divided into four courses, and the teachers will be four officers, two of whom will be supplied by the War Office and two by the Red Cross Association. A final examination will give the successful examinee the right to the "Diploma di Infermiera della Croce Rossa Italiana," together with a "medaglia di riconoscimento" (medal of recognition) bearing the emblem of the Geneva Convention and the name of the holder of the diploma. Every such holder will be morally obliged to be in readiness for every call in case of the mobilisation of the Italian Red Cross. Other duties are specified in the programme of qualification but as these are identical with those imposed by the Red Cross societies of other nations they need not be detailed here. The school, I may add, will be under the direction of Lieutenant-Colonel Parisi, director of the military hospital of Rome; of Dr. Postemski, principal medical inspector of the Italian Red Cross; of Colonel Panara, medical officer of the Reserve; of the Duchess Amalia Tortonia, of the Countess Camerana, and of the Countess Pelagallo di Marazzano. As I write, I am informed that the teaching staff will consist of the Chevalier Professor Giovanni Memmo and Dr. Umberto Riva of the Army Medical Department, and of the Chevalier Dr. Augusto Bisso and the Chevalier Dr. Bonaventura Pasca, medical captains of the Red Cross.

"Frost-bite and Wolf-bite."

If up to now the winter on the Italian slopes of the Alps has been comparatively mild—so mild as to tempt some of the Piedmontese Alpine Club to arduous expeditions—the same cannot be said of the southern ranges of the Apennines. This time last year THE LANCET, under the above title, recorded the disastrous incursion of famished wolves into the haunts of man—one heard of them in the Abruzzi having, under stress of cold and hunger, assailed a linesman on the highway, and, in spite of his armed defence, torn him to pieces, leaving little besides his blood-stained sword to attest his fate. Further south last week in the Basilicata, not far from the town of Potenza, a similar tragedy well nigh befel a wood cutter and his son driving home on a cart from the plantation. It was broad day—not the dusk of the evening, as in the former instance—when the two were assailed by wolves, the fiercest of which remained in single combat with the wood-cutter, while the others were being scared away by his son. The father, a man of powerful build and dauntless courage, grappled with the brute, and after a desperate struggle succeeded in pinning it to the ground. The wolf, however, still made formidable fight, and to such effect that the wood-cutter, already severely bitten and losing blood, might have got the worst of it had not his son opportunely fetched him an axe from the vehicle. With this he dealt the brute a decisive blow and the struggle was at an end—leaving him, however, as stated, horribly lacerated, particularly in the hands, a proper subject for the Pasteur Institute. The Government, it is suggested, might offer a prize for each of these dangerous animals brought in dead, and this would be a finer, and also a more serviceable, sport than the steady destruction of the chamois, which is rapidly disappearing from Alpine Italy, till it bids fair to live only in Carducci's magnificent ode, entitled "Il Piemonte."

Feb. 2nd.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Medical Inspection of Schools.

THE Ministry of Education, in which medical influence is undoubtedly active, has again issued an order dealing with hygienic measures to be adopted in regard to the supervision of schools. School hygiene is to be regarded as an integral part of the sanitary administration of the different counties and the reports sent in by the respective boards will have to show clearly to what extent schools are visited by medical men at regular periods. The order enables the local authorities to appoint visiting medical officers for the schools, especially for the so-called elementary schools, in which children from six to 14 years of age receive instruction. The order empowers them also to institute medical supervision in infants' schools (where the ages of the children are from four to six years), in technical schools, and in commercial schools. A suggestion as to the time of inspection of the children is given. The medical officer must examine new pupils on their first arrival and must afterwards visit the schools at intervals of about four or six months, unless a local outbreak of epidemic disease, such as parotitis, measles, scarlet fever, or diphtheria, makes it advisable to pay more frequent visits. Special attention is to be given to diseases of the eye, ear, throat, and teeth, as well as to the ventilation and the lighting of the class-rooms. The expenditure will be borne by the ratepayers and the Government. The school medical officer will not undertake the treatment of the little patients but his work will be rather of a preventive nature. The fees for treatment have to be found by the parents or friends. Another memorandum just issued deals with the care of feeble-minded or crippled children and with the proper treatment and care of the deaf and dumb. There is good provision for this class of defectives in Austria and the Ministry of Education only calls the attention of teachers to its existence. For the higher classes of the public schools gymnastics are recommended as an antidote to the ill-effects of the demands made by modern education on the mental faculties.

A Case of Lymphatic Leukæmia with Chylothorax.

At a recent meeting of the Medical Society Dr. Strasser showed a man who had been suffering from diarrhœa and swollen glands for some time previously to his admission to hospital. A cubic millimetre of his blood contained 4,000,000 erythrocytes and 437,000 leucocytes, of which 98 per cent. were lymphocytes. A few weeks after admission the hæmoglobin index, which had been constantly 74 per cent., sank still lower, and he had a sudden attack of dyspnœa, caused by accumulation of fluid in the right pleural cavity. Puncture had to be performed twice, the fluid which was withdrawn being turbid and yellowish in colour with a specific gravity of 1·16; it contained 7 per cent. of albumin and 3 per cent. of fat with some sugar, and was, in fact, typical chyle. Although the exudation reached to the level of the third rib the heart was not displaced, a condition which Dr. Strasser thought was due to infiltration of the pleura making it rigid. The chylothorax was caused either by bursting of the stopped and efforts were made to restore harmony, but without effect. Later, it is stated, the sub-committee informally requested the physician-superintendent to dismiss three of the assistants and that he declined to do so, as he had no complaint against them. On Jan. 7th, however, the three assistants received a letter from the medical officer of health of Glasgow dismissing them. This "dismissal" the resident physicians refused to accept but eventually left the hospital under protest. The final stage in the episode so far is an intimation to the town clerk from the Local Government Board stating that the Board has received a memorial from the resident physicians at Ruchill Hospital praying the Board to institute an inquiry into the conditions existing at the hospital. The statements in the memorial appear to the Board to constitute a *primâ-facie* case for inquiry by it in the interests of public health. Before coming to a decision, however, it has deemed it advisable to hold a preliminary investigation with the view of ascertaining whether the circumstances call for a full and detailed inquiry. With this object it has appointed Dr. Henry H. Littlejohn, professor of forensic medicine in the University of Edinburgh, a commissioner to inquire and report. As a result of Professor Littlejohn's preliminary report the Local Government Board has intimated that it has appointed Mr. Donald Crawford, K.C., sheriff of Aberdeenshire, a commissioner "to inquire and report upon the complaints of overcrowding and understaffing of Ruchill Fever Hospital and on the administration and management of the hospital."

The Epidemic of Enteric Fever in Glasgow.

The epidemic of enteric fever in the west-end of Glasgow seems to be now on the wane and it is not expected that many more cases will be reported. At the time of writing, however, there are 156 cases of enteric fever in the city as compared with 139 in the previous week, and of these 90 have been traced to the same source, a contaminated milk-supply.

The New Convalescent Home at Edzell.

On Jan. 13th a meeting of the managers of the Montrose Asylum and Infirmary was held to discuss an unfortunate hitch which has occurred in connexion with the building of the new convalescent home at Edzell. The meeting, which lasted about one and a half hours, was held in private. Considerable progress has already been made with the building, which was estimated to cost £2500. The building operations are, however, at present suspended and at the meeting the managers heard lengthy correspondence on the subject and also a report by Mr. John Sim, the architect. After free discussion the managers unanimously decided that no arrangement would satisfy them which did not involve the pulling down of the building.

Seaforth Sanatorium, Ross-shire.

This institution was formally opened on Jan. 16th in the presence of a large and representative gathering and of the town councils of Dingwall and Tain. A message from the King wishing success to the sanatorium was received, and also one from the Local Government Board of Scotland offering congratulations to Colonel and Mrs. Stewart Mackenzie of Seaforth, the donors of the institution. Mrs. Stewart Mackenzie was presented with a gold key by Mr. Macbeth, the architect, with which she opened the main entrance and declared the Seaforth Sanatorium open. The foundation-stone of this institution was laid rather more than a year ago by Mrs. Stewart Mackenzie. It is situated over 200 feet above sea-level, about two miles from Dingwall, and just behind the village of Maryburgh. It has been endowed by the donors to the extent of £100,000, and they have also given the site, large grounds, building, and equipment. The institution is available for both sexes; one-third of the accommodation is reserved for the Island of Lewis, and the other two-thirds for the mainland of Ross and Cromarty. The total accommodation in the meantime consists of 12 beds but this may materially be enlarged by the addition of outside cubicles. Anyone resident in the county who cannot afford to go to a commercially conducted sanatorium may be admitted and it is hoped that an educational as well as a curative work may be done through the institution. The building is divided into two blocks with the administrative department in the centre. The patients' rooms are uniform with the exception of the end rooms which are larger and intended for the treatment of special cases. While in the meantime each patient will have a room, any of the rooms might be used for two beds and the larger ones for four. The rooms open on to a broad plat which runs along the entire length of the structure and on to which beds can be drawn and a constant current of air, regulated at will, can be had in each room. The floorings are of pitch pine; all the corners of the rooms are rounded and all the furnishings are on the most approved principles. The building is three storeys high in the centre and contains matron's and nurses' rooms, dispensary, and pathological research rooms for the resident physician. During the lifetime of Colonel and Mrs. Stewart Mackenzie the institution will be managed by them. Afterwards it will be controlled by a body of trustees and a local committee.

The Notification of Births Act and Scottish Medical Men.

An influential deputation of the Aberdeen Medico-Chirurgical Society, representing nearly the whole of the medical profession in Aberdeen and the immediate neighbourhood, waited upon the town council of that city on Jan. 20th to express the views of the society on the proposed adoption of the Notification of Births Act by Aberdeen. The deputation, which consisted of Dr. G. Williamson (president), Dr. J. Marnoch (secretary), Dr. A. H. Lister (treasurer), Dr. John Gordon, Dr. G. M. Edmond, and Dr. R. G. Mackerron, advanced in a very able manner arguments against its adoption such as have been laid before the readers THE LANCET more than once. They did not oppose the objective of the Act but only the method of its proposed administration—namely, by means of gratuitous certificates supplied under penalty by medical men attending births. They pointed out that in this matter no exercise of professional skill is involved and that the notification could be made by the father or nearest relative attending the mother, as only a simple statement of fact was required. It was contrary to the usage of the profession to give any information regarding patients, except such as the law required for the public welfare and which could only be supplied by a medical man. Further, if a mother wished to conceal a birth she would be less likely than formerly to summon medical aid in a place where the Act had come into operation. Finally, the injustice to medical men of expecting them to perform another gratuitous service to the State was shown and the case of Manchester, the council of which city has rejected the Act after its adoption by the sanitary committee, was cited. The deputation was heard very courteously by the Aberdeen bailies and in consequence Councillor Kendall Barnett withdrew his motion to accept the Act and substituted one to send it back to the public health committee for further consideration in the light of the expression of medical opinion which the council had heard. This vigorous defence of professional rights may be commended to the notice of medical societies elsewhere. —At the first meeting of the newly elected Laurencekirk district committee of Kincardine county council a circular was submitted from the Local Government Board explaining the Notification of Births Act, 1907, and inclosing a form of application for its adoption. The chairman moved that the Act be not adopted. Mr. Low seconded the motion and pointed out that the Act was an injustice to the medical profession, because it imposed a penalty for neglect of duty for which they received no payment. The motion was agreed to unanimously.

Crathie and Braemar Parish Council: Medical Officership.

In THE LANCET of Jan. 4th, p. 60, some details were given of a conflict of opinion which has arisen in the parish council of Crathie and Braemar in Aberdeenshire with reference to the appointment of Dr. William Brown of Braemar as medical officer to the council. Some of the members are very hostile to Dr. Brown and at the meeting held on Dec. 13th, 1907, a majority of 6 votes to 2 were in favour of dismissing him. The subject was again discussed at a meeting of the parish council held on Jan. 29th. The chairman said that he had communicated with the Local Government Board for Scotland, giving a statement of the various steps which had been taken during the past year in connexion with the appointment of the medical officer, and that the Local Government Board had replied, stating that Dr. Brown's appointment was in order, and that there was no good reason for doubting its legality. The Local Government Board also stated that a medical officer, unless his agreement specially provides to the contrary, holds office for one year and his engagement may be terminated at the end of that year if due notice, say, of six weeks or two months be given to him. If no such notice be given he holds office by "tacit relocation" for another year. The Board also strongly deprecated the removal of a medical governing the manufacture of foods under the "Pure Food Laws." But his rulings have been severely criticised by dealers in foods. It is alleged by the fruit driers of California that the quantity of sulphur specified as the maximum by Dr. Wiley's decision is one-third that allowed in Germany which has the strictest food regulations of all countries. The complaints against Dr. Wiley's decisions are so numerous and urgent that the President has determined to appoint a commission of expert chemists who shall constitute a board to make a final decision on all of these questions. In order to secure the most competent chemists the President has requested the presidents of the universities of Johns Hopkins, Virginia, California, Yale, and the Northwestern of Chicago each to recommend a chemist whom he will appoint on a board which shall determine finally all questions arising under the law.

General Immigration Statistics.

Recently published statistics by the Immigration Restriction League show that during the year 1907 there were landed in this country 1,285,349 immigrants, the largest number received in any one year since 1821. The change in the national groups of immigration since 1869, a period of 37 years, is interesting. The percentage of immigrants, from Austria-Hungary, Italy, and Russia in 1869 was 0·9, and from the United Kingdom, France, Germany, and Scandinavia it was 73·8; in 1907 the former group was 71·3 per cent. and the second group 17·1 per cent. The change in the relative percentage of these two groups of immigrants began in 1896. The largest elements in immigration at present are as follows: Southern Italian, 242,497; Hebrew, 149,182; Polish, 138,033; German, 92,936; Magyar, 60,071; and Scandinavian, 53,425. The percentage of illiterates in total immigration was 23·9; the lowest percentage in each 100 immigrants over 14 years of age who cannot write and cannot read and write their own language was Scotch 1·0, and the highest percentage was Portuguese, 76·6. The present immigration law excludes the following classes:—The mentally unfit—viz., idiots, imbeciles, feeble-minded, and insane; the physically unfit—epileptics, tuberculous, and persons afflicted with a loathsome or contagious disease; the morally unfit—prostitutes, procurers, polygamists, anarchists, and convicts; the economically unfit—paupers, persons likely to become a public charge, professional beggars, contract labourers, and assisted emigrants. The number debarred and deported in 1907 was 14,059, or 1·1 per cent. of the total number of arrivals.

The Federal Employers' Liability Law Void.

For more than 20 years the railroad men of the United States have been struggling to secure a law which protected them from the accidents to which they are especially liable. The President urged the passage of such a Bill and at the last session of Congress it was finally passed and became law. The law was brief and provided for the extension of the employers' liability to all common carriers engaged in interstate commerce and practically abolished the "Fellow Servant" rule. The doctrine of contributory negligence was modified so as not to bar recovery where the negligence of the employee was slight and the negligence of the employer was gross in comparison—the newer doctrine of "comparative contributory negligence." On the passage of the law several railroads united to test its constitutionality, with the result that it has been declared unconstitutional by the highest court and is now void.

Jan. 25th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Melbourne Hospital.

THE question of a site for rebuilding the Melbourne Hospital remains unsettled, although it provides a topic for newspaper correspondence and has been the subject of several conferences between various bodies interested. Dr. J. W. Springthorpe is energetic in support of the proposal to rebuild on the present site, while Dr. R. R. Stawell expresses the opinion of the advocates for removal. At a meeting of the hospital medical staff a motion affirming the desirability of procuring a larger site was carried by 11 votes to five. The present block is about four acres in extent and the proposed new area, which is at present occupied by the pig and horse market, would be something between 12 and 14 acres, but it is about a mile farther out of the city. The opponents of removal assert that this extra distance is a serious drawback and that the site itself is dusty and exposed to the north winds. The advocates for a new site affirm that the present situation is too small for a modern self-contained hospital and clinical school, and that the "pig-market" block has the advantage of being in the immediate vicinity of the University Medical School. Under the terms of the gift of £100,000 for rebuilding purposes made by the trustees of the Wilson estate, the question of site had to be decided upon within six months. About four months of the term have already elapsed. The trustees also retained the right of approval of any site determined upon.

The Danysz Microbe.

Sir William Lyne is determined to carry out the Federal policy of "Australia for the Australians" even to denying admission to imported microbes. Dr. F. Tidswell has shown that the Danysz microbe, or one indistinguishable from it, is already known in New South Wales and has caused epizootics among rabbits. Sir William Lyne admits that this places a new aspect on the question of trying the Danysz method on the mainland, but states that it is certain that Parliament would never permit the liberation of the microbe introduced to Australia by Dr. Danysz. Meanwhile the pastoralists demand that a trial shall be made in the rabbit-infested areas of the interior.

St. Vincent's Hospital.

The engineering inspector of the Board of Public Health has reported that St. Vincent's Hospital, Melbourne, is "excessively overcrowded." St. Vincent's is the most recent hospital building in Australia and is fitted with every modern improvement. The present structure forms only a part of the whole design and under the Board's standard is available for 76 patients. At the time of the inspector's visit 124 patients were under treatment, patients being "placed in the balconies, in the lobbies, and other parts of the building not set apart for such a purpose." Dr. Norris (chairman of the Board of Health) remarked that the state of affairs was "nothing short of scandalous" and immediate action was ordered in the direction of a peremptory letter to the hospital authorities and a communication with the Board's solicitors. The hospital authorities have replied that so great has been the demand in urgent cases that they have been unable to turn them away and that the hospital is so equipped with balcony and corridor space that some patients can be temporarily accommodated there without inconvenience.

Infants' Food.

Recently at the Richmond (Victoria) police court tradesmen were fined with costs for selling well-known brands of infants' food in contravention of the Pure Foods Act. The editor of the *Chemist and Druggist* has written to the press to point out that the prosecution was for failure to state that the foods must not be used for infants under six months. The Pure Foods Act requires that infants' foods containing starch must be labelled or sold with the statement that they are not intended for children under the age of six months.

Home for Consumptives.

On Dec. 14th last the sanatorium for consumptive women was opened at Thirlmere, New South Wales, by the State Governor, Sir Harry Rawson. The site was devoted to the purpose originally by a Mr. Goodlet, but subsequently was placed under the management of the Queen Victoria Home for Consumptives. Eventually the site was purchased and with the new buildings has cost £10,000. It will accommodate 50 patients. Since the male wing was opened at King's Tableland the practice of mixing the sexes at Thirlmere has been abandoned. The medical supervision will be in the hands of Dr. Eric Sinclair.

Action for Libel.

Mr. S. B. Helwig who is registered as M.D. Univ. of Heidelberg, 1899, recently brought an action against the proprietors of the Ballarat *Echo*, claiming £1000 damages for alleged libellous paragraphs stating that the plaintiff had victimised a resident of Ballarat in respect to an alleged cure for gall-stones. The plaintiff has practised for some time at Pakenham, a small village near Melbourne. He is alleged to have claimed by advertisement in the public press to be able to remove gall-stones by means of a special medical treatment. The paragraphs complained of had reference to a patient who had undergone the treatment without benefit. A stopped and efforts were made to restore harmony, but without effect. Later, it is stated, the sub-committee informally requested the physician-superintendent to dismiss three of the assistants and that he declined to do so, as he had no complaint against them. On Jan. 7th, however, the three assistants received a letter from the medical officer of health of Glasgow dismissing them. This "dismissal" the resident physicians refused to accept but eventually left the hospital under protest. The final stage in the episode so far is an intimation to the town clerk from the Local Government Board stating that the Board has received a memorial from the resident physicians at Ruchill Hospital praying the Board to institute an inquiry into the conditions existing at the hospital. The statements in the memorial appear to the Board to constitute a *primâ-facie* case for inquiry by it in the interests of public health. Before coming to a decision, however, it has deemed it advisable to hold a preliminary investigation with the view of ascertaining whether the circumstances call for a full and detailed inquiry. With this object it has appointed Dr. Henry H. Littlejohn, professor of forensic medicine in the University of Edinburgh, a commissioner to inquire and report. As a result of Professor Littlejohn's preliminary report the Local Government Board has intimated that it has appointed Mr. Donald Crawford, K.C., sheriff of Aberdeenshire, a commissioner "to inquire and report upon the complaints of overcrowding and understaffing of Ruchill Fever Hospital and on the administration and management of the hospital."

The Epidemic of Enteric Fever in Glasgow.

The epidemic of enteric fever in the west-end of Glasgow seems to be now on the wane and it is not expected that many more cases will be reported. At the time of writing, however, there are 156 cases of enteric fever in the city as compared with 139 in the previous week, and of these 90 have been traced to the same source, a contaminated milk-supply.

The New Convalescent Home at Edzell.

On Jan. 13th a meeting of the managers of the Montrose Asylum and Infirmary was held to discuss an unfortunate hitch which has occurred in connexion with the building of the new convalescent home at Edzell. The meeting, which lasted about one and a half hours, was held in private. Considerable progress has already been made with the building, which was estimated to cost £2500. The building operations are, however, at present suspended and at the meeting the managers heard lengthy correspondence on the subject and also a report by Mr. John Sim, the architect. After free discussion the managers unanimously decided that no arrangement would satisfy them which did not involve the pulling down of the building.

Seaforth Sanatorium, Ross-shire.

This institution was formally opened on Jan. 16th in the presence of a large and representative gathering and of the town councils of Dingwall and Tain. A message from the King wishing success to the sanatorium was received, and also one from the Local Government Board of Scotland offering congratulations to Colonel and Mrs. Stewart Mackenzie of Seaforth, the donors of the institution. Mrs. Stewart Mackenzie was presented with a gold key by Mr. Macbeth, the architect, with which she opened the main entrance and declared the Seaforth Sanatorium open. The foundation-stone of this institution was laid rather more than a year ago by Mrs. Stewart Mackenzie. It is situated over 200 feet above sea-level, about two miles from Dingwall, and just behind the village of Maryburgh. It has been endowed by the donors to the extent of £100,000, and they have also given the site, large grounds, building, and equipment. The institution is available for both sexes; one-third of the accommodation is reserved for the Island of Lewis, and the other two-thirds for the mainland of Ross and Cromarty. The total accommodation in the meantime consists of 12 beds but this may materially be enlarged by the addition of outside cubicles. Anyone resident in the county who cannot afford to go to a commercially conducted sanatorium may be admitted and it is hoped that an educational as well as a curative work may be done through the institution. The building is divided into two blocks with the administrative department in the centre. The patients' rooms are uniform with the exception of the end rooms which are larger and intended for the treatment of special cases. While in the meantime each patient will have a room, any of the rooms might be used for two beds and the larger ones for four. The rooms open on to a broad plat which runs along the entire length of the structure and on to which beds can be drawn and a constant current of air, regulated at will, can be had in each room. The floorings are of pitch pine; all the corners of the rooms are rounded and all the furnishings are on the most approved principles. The building is three storeys high in the centre and contains matron's and nurses' rooms, dispensary, and pathological research rooms for the resident physician. During the lifetime of Colonel and Mrs. Stewart Mackenzie the institution will be managed by them. Afterwards it will be controlled by a body of trustees and a local committee.

The Notification of Births Act and Scottish Medical Men.

An influential deputation of the Aberdeen Medico-Chirurgical Society, representing nearly the whole of the medical profession in Aberdeen and the immediate neighbourhood, waited upon the town council of that city on Jan. 20th to express the views of the society on the proposed adoption of the Notification of Births Act by Aberdeen. The deputation, which consisted of Dr. G. Williamson (president), Dr. J. Marnoch (secretary), Dr. A. H. Lister (treasurer), Dr. John Gordon, Dr. G. M. Edmond, and Dr. R. G. Mackerron, advanced in a very able manner arguments against its adoption such as have been laid before the readers THE LANCET more than once. They did not oppose the objective of the Act but only the method of its proposed administration—namely, by means of gratuitous certificates supplied under penalty by medical men attending births. They pointed out that in this matter no exercise of professional skill is involved and that the notification could be made by the father or nearest relative attending the mother, as only a simple statement of fact was required. It was contrary to the usage of the profession to give any information regarding patients, except such as the law required for the public welfare and which could only be supplied by a medical man. Further, if a mother wished to conceal a birth she would be less likely than formerly to summon medical aid in a place where the Act had come into operation. Finally, the injustice to medical men of expecting them to perform another gratuitous service to the State was shown and the case of Manchester, the council of which city has rejected the Act after its adoption by the sanitary committee, was cited. The deputation was heard very courteously by the Aberdeen bailies and in consequence Councillor Kendall Burnett withdrew his motion to accept the Act and substituted one to send it back to the public health committee for further consideration in the light of the expression of medical opinion which the council had heard. This vigorous defence of professional rights may be commended to the notice of medical societies elsewhere. —At the first meeting of the newly elected Laurencekirk district committee of Kincardine county council a circular was submitted from the Local Government Board explaining the Notification of Births Act, 1907, and inclosing a form of application for its adoption. The chairman moved that the Act be not adopted. Mr. Low seconded the motion and pointed out that the Act was an injustice to the medical profession, because it imposed a penalty for neglect of duty for which they received no payment. The motion was agreed to unanimously.

Crathie and Braemar Parish Council: Medical Officership.

In THE LANCET of Jan. 4th, p. 60, some details were given of a conflict of opinion which has arisen in the parish council of Crathie and Braemar in Aberdeenshire with reference to the appointment of Dr. William Brown of Braemar as medical officer to the council. Some of the members are very hostile to Dr. Brown and at the meeting held on Dec. 13th, 1907, a majority of 6 votes to 2 were in favour of dismissing him. The subject was again discussed at a meeting of the parish council held on Jan. 29th. The chairman said that he had communicated with the Local Government Board for Scotland, giving a statement of the various steps which had been taken during the past year in connexion with the appointment of the medical officer, and that the Local Government Board had replied, stating that Dr. Brown's appointment was in order, and that there was no good reason for doubting its legality. The Local Government Board also stated that a medical officer, unless his agreement specially provides to the contrary, holds office for one year and his engagement may be terminated at the end of that year if due notice, say, of six weeks or two months be given to him. If no such notice be given he holds office by "tacit relocation" for another year. The Board also strongly deprecated the removal of a medical

Obituary.

SIR THOMAS McCALL ANDERSON, M.D. GLASG., F.F.P.S. GLASG.,

REGIUS PROFESSOR OF MEDICINE IN THE UNIVERSITY OF GLASGOW.

THE tragically sudden death of Sir Thomas McCall Anderson on the evening of Jan. 25th has removed a prominent personality from the ranks of the profession in Glasgow and the West of Scotland and a popular and highly successful teacher from the Glasgow Medical School in which he laboured with conspicuous ability for a period of nearly 50 years. On that evening he was present at the anniversary dinner of the Glasgow Ayrshire Society as the guest of his old friend the chairman, Surgeon-Colonel Robert Pollok, and appeared to be in his ordinary health and spirits. In felicitous terms he proposed the last toast on the list, that of the directors and other office-bearers of the society. Immediately afterwards he left the dining-room in company with his friend and colleague Sir Hector C. Cameron, apparently quite well, but on his way down the staircase he suddenly fainted and, surrounded by a number of medical friends who like himself had been guests of the chairman, he expired in a few minutes from heart failure. He had promised Dr. Pollok to be present and to propose a toast. He had felt somewhat tired during the day but in spite of the remonstrances of his family he felt that he could not disappoint his old friend and pupil who had been called to the honourable office of chairman of the society. He attended the dinner and kept his promise, with the tragical result which has just been stated. During the past year or more, probably as the result of a sudden but transient illness of an apoplectic nature, he had not enjoyed his usual vigorous good health, and last summer, on the advice of his medical friends, he took a prolonged holiday from teaching and professional work. He had benefited by the rest and change so much that he was able to resume his professorial duties at the beginning of the present winter session. At the meeting of the General Medical Council in November last he appeared to be in good health and took an active part in all the business of the session. He also attended the meeting of the Scottish branch council in Edinburgh last month.

Thomas McCall Anderson was born in Glasgow in 1836 and came of a family long and honourably connected with the city. His father, Dr. Alexander Dunlop Anderson (1794-1871), was the son of a merchant in Greenock and nephew of Dr. John Anderson, professor of natural philosophy in the university and founder in 1796 of the "Andersonian" university which is still famous as the leading extramural medical school in Glasgow. Through the Dunlops his family was intimately connected with the university, one of the Dunlops having been principal at the end of the seventeenth and another professor of Greek during the greater part of the first half of the eighteenth century. It will thus be seen that he came from a family which was able to give him a good start on the journey of life, and he himself soon proved that he was fitted and willing to make the very best use of his hereditary endowments. After a brilliant career as a medical student in the university of his native city he graduated "with honours" in 1858. For the succeeding two years he acted as one of the resident assistants in the Glasgow Royal Infirmary, in which institution his father had served during a number of years on the visiting staff. He then spent some time at Vienna and other great continental schools, and soon afterwards he settled in practice in Glasgow. In these early years he securely laid the foundations of his future success as a teacher and physician by his enthusiasm for his medical work and his tireless industry in the prosecution of it. He possessed that capacity for taking pains which is said to be akin to genius. Two old notebooks given by him to a friend many years ago bear abundant evidence of this. One of them contains full records of the symptoms and treatment of the rarer cases coming under his observation, and the other full notes of the books he studied. In the list of books thus annotated are such classics as Louis on Phthisis, Williams on Diseases of the Chest, Brinton on Ulcer of the Stomach, Virchow on the Cellular Pathology, Ricord on Syphilis, Gairdner and Garrod on Gout, Brown-Séquard on Epilepsy, Adams on Rheumatic Gout, and many others. In such a thorough manner did he prepare himself for his life's work.

Soon after settling in Glasgow he was appointed professor of the practice of medicine in the "Andersonian" College and somewhat later one of the visiting physicians to the Glasgow Royal Infirmary. From this time his success as a teacher and a physician was rapid and was maintained till the end of his long career. When the clinical school of the University was removed from the Royal to the Western Infirmary in 1874 he was appointed professor of clinical medicine in the University and one of the visiting physicians to the newly founded infirmary, where by far the greater part of his clinical work was done, and in the wards of which he was on full duty at the time of his death. In addition to his great industry another element in his success was the methodical manner in which he arranged his work. The proof of this is found in the fact that his great work on diseases of the skin was written at a time when his consulting practice was at its highest level and his popularity as a clinical teacher at its greatest. Regularly every afternoon in the midst of his numerous academic, professional, and social engagements an hour or two was devoted to the writing of the book. His custom then was to make pencil notes late at night and to dictate them the next afternoon as they were to appear in print to his amanuensis. His untiring industry and his method of working were an example and an inspiration to his students and assistants.

From what has been said it will readily be understood that the reason of McCall Anderson's great popularity and success as a teacher, especially of clinical medicine, is not far to seek. In the old Royal Infirmary days, before the University migrated to the west, he had already displayed his powers as a teacher, and his clinical classes were always most numerously attended. His definite aim in these days was to raise the standard of clinical teaching. He saw that in order to be effective clinical study and practice should be something more than a mere "walking the hospital." He set himself definitely so to organise his large classes that so far as possible individual students should be brought into personal contact with the cases. For this purpose in the most thorough manner he adopted the tutorial system, dividing the students into groups so that the elements of physical diagnosis and urinary analysis might be efficiently taught. The same methods were adopted when he went in 1874 to the Western Infirmary as Professor of Clinical Medicine in the University. Similar popularity attended him in his new sphere, and to the end in the Western Infirmary his clinical classes were always the largest. His great success in clinical teaching was due mainly to three characteristics: (1) to his clear and systematic method of exposition and demonstration; (2) to his intense concentration upon the subject in hand, which prevented his being led into the discussion of irrelevant matters; and (3) to his admirable powers of organisation in arranging for the teaching of large classes of students. These are qualities which, if combined with enthusiasm and industry, are bound to command success in clinical teaching. Everyone recognised that under the conditions of medical education which have up to now prevailed in this country no better method of instruction than that carried out by McCall Anderson could be devised for laying a sure foundation in the study and practice of clinical medicine.

As a physician Sir Thomas McCall Anderson may be described as at once practical and sagacious. His powers were greater in the direction of therapeutics than in that of pathology or the minutiæ of diagnosis. He did not belong to the expectant school and was never content to rely merely on the *vis medicatrix naturæ*. He believed thoroughly in the practical applications of the medical art and nothing delighted him more than to demonstrate to his students the beneficial effects of the drugs and therapeutic measures which he had prescribed. Indeed, this was the part of his teaching from which many of his students felt that they had profited most. And outside the wards of the infirmary his clear and common-sense instructions as to the treatment to be carried out in a given case were greatly valued by the numerous medical men who were in the habit of seeking his advice as a consultant. For many years he enjoyed a very extensive consulting practice. He did not, however, confine himself to general medicine; he also had a deservedly high reputation as a specialist in diseases of the skin. It was, indeed, as a dermatologist perhaps that he was best known in England and on the continent of Europe. Very early in his professional career he was instrumental in

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Disinfection of Uniforms.

WITH a view to avoid the risks of the transmission of infectious diseases throughout the army by means of every-day kit the Minister for War has ordered that disinfection shall be obligatory for all articles commonly in use, whether before their return into store or before they have been handed over from one man to another without being returned to store. The regulations now applicable to the use of formaldehyde vapour shall henceforward be applicable to headgear, boots or shoes, and spats.

Poisonous Milk from Cows Fed on Beet.

At a meeting of the Pædiatric Society held on Jan. 21st M. Decherf mentioned that an epidemic of acute enteritis had broken out in November among the children who attended his clinique at Tourcoign. No obvious cause appeared for this, as all the milk had been sterilised in the usual way. Inquiry eventually showed that owing to the lack of ordinary forage the cows had been fed upon beet leaves and red cabbage, vegetables which are well known to give both milk and butter a particular flavour. M. Decherf added that he had noticed a similar epidemic in the September of 1903. In this case it was due to the cows having been fed upon beet which had been kept in silos during the summer and which had fermented. The enteritis due to this cause presents the same features as that caused by microbe-infected milk but feeding by skim milk, which has a favourable effect upon microbial enteritis, has no effect upon toxic enteritis.

Expert Medical Evidence and the Criminal Law in France.

At a meeting of the Academy of Medicine held on Jan. 21st M. Thoinot and M. Lacassagne communicated a paper in which they pointed out how very little guarantee expert evidence under the present regulations offered to an accused man. If the diploma of doctor gives the holder the right to be summoned by the court as an expert it is no guarantee of his competence to act as such. Reforms as to the status of the medico-legal experts have been demanded for some time and a Bill to this effect has been before the Senate since 1899. M. Thoinot and his colleague ask that every condition should be exacted from expert witnesses so as to guarantee their competence and that legislation to this effect should be forthcoming.

The Cholera.

The greatest mortality from cholera takes place in India either in the height of summer or in the depth of winter. At the present time cholera imported from India is present at Mecca. After the Bairam festival, which this year occurred about Jan. 15th, there was reason to fear that the return of pilgrims would rapidly infect Mesopotamia, Persia, and Egypt. Another source of infection to be feared is that when the Hedjaz railway is completed it will bring Medina within four days of Damascus, thus doing away with the barrier, hitherto almost insurmountable, which the passage of the desert has offered. At the same meeting of the Academy of Medicine M. Chantemesse and M. Borel communicated a paper in which they said that the pilgrim routes, whether by sea or land, should be under strict supervision.

Statistics of Diphtheria.

At a meeting of the Hospitals Medical Society held on Jan. 7th M. Marfan gave the statistics of the diphtheria block at the Hospital for Sick Children from May 1st, 1906, to the same date in 1907. Of 789 patients admitted to the block 555 were suffering from diphtheria. Of these 555 patients the total mortality was 10·45 per cent. and the corrected mortality (*mortalité réduite*) 6·4 per cent. It will be seen, therefore, that the notable diminution in the mortality from the disease which has been observed of late years is fully maintained.

Sleeping Sickness in a White Man.

At a meeting of the Hospitals Medical Society held on Jan. 31st M. Guillain and M. Martin showed a man who had been attacked in the Congo with sleeping sickness, the diagnosis having been confirmed by the finding of trypanosomata. After he arrived in Paris paralysis with atrophy of the arm supervened, the characteristics being similar to those observed in syphilitic paraplegia. The groups of muscles specially affected were those of the thenar and hypothenar eminences. There were also present affections of sensation, exaggerated patellar reflex, Babinski's sign on the left side, and some modifications of the electrical reactions. All the symptoms disappeared after treatment with atoxyl. The presence of the trypanosoma in this case made it easy to eliminate all the other causes to which the symptoms might have been due. The atoxyl was administered as follows: first, one injection of 0·5 of a gramme; secondly, seven injections of 1 gramme; and finally, 11 injections of 0·5 of a gramme.

Feb. 4th.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

Brown Glasses as Eye Protectors.

IN a recent number of the *Revue Médicale de la Suisse Romande* Dr. Gonin has published his investigations on the use of coloured glasses to protect the eyes against the detrimental influence of strong light. He says that healthy persons only need these glasses when exposed to dazzling artificial light or when traversing snowfields and glaciers. The ultra-violet rays prove more detrimental to the conjunctiva than to the retina. Snow-blindness does not supervene suddenly as in the cases of blindness provoked by looking at the sun during an eclipse without the protection afforded by dark glasses. The retina is protected by the crystalline lens which absorbs ultra-violet rays (Widmark, Birch-Hirschfeld). Even the interposition of plain uncoloured glass acts as a protective to the retina. Dr. Gonin strongly recommends brown glasses as being capable of absorbing the greater part of the blue and violet rays without obscuring the vision, as in the case of the blue and black glasses which are generally in use. They have proved of special benefit to persons of a certain age with already diminished eyesight. Dr. Gonin has experimented with these glasses on Alpine tours and warmly recommends them; he has also found them useful in cases of retinitis pigmentosa, choroiditis, and neurasthenia with eye fatigue, whereas dark glasses are indicated when complete rest is necessary for the eye, as in the case of acute iritis, detachment of the retina, or atrophy of the optic nerve. In a communication to the Academy of Medicine Professor Motais of Angers has indicated four different shades of these brown glasses, and it is desirable that opticians should always adhere to the same formula.

Epidemic Cerebro-spinal Meningitis.

Dr. Charlotte Müller, assistant physician at the Medical Clinique of Zürich, has published lengthy details of 29 cases of so-called "epidemic" cerebro-spinal meningitis treated during the last two years under the care of Professor Eichhorst. The differential diagnosis between epidemic and tuberculous meningitis is insecure when resting only on clinical symptoms, though now and then the appearance of tubercles in the choroid and the absence of herpes febrilis determine the tuberculous origin of the brain affection. Neither chemical examination of the exudation nor microscopic examination of the blood supplies any definite information; this can only be obtained by bacteriological investigation, and even that may be misleading, as one fatal case proved. Out of 36 cases of purulent meningitis observed in the clinique 29 were due to the meningococcus of Weichselbaum, two had to be attributed to the diplococcus lanceolatus, three to the streptococcus mucosus (Schottmüller), one to the staphylococcus pyogenes aureus, and one to a doubtful form of diplococcus. Thus, 80 per cent. of all the cases were due to the epidemic variety of the disease, though there could be no question of an epidemic prevailing in and about Zürich, as the various cases had no connexion with each other. Some clinical symptoms seem of importance as regards diagnosis. Generally the spleen was not enlarged and in almost half the cases herpes febrilis was observed. In 26 out of 36 cases lumbar puncture was successfully performed. The serum treatment with anti-meningococcus serum, prepared by the Swiss Serum Institute according to the method of Kölle and Wassermann, proved ineffectual, as the rate of mortality of 75 per cent. was not influenced thereby.

Zürich, Feb. 2nd.

thoracic duct consequent on the pressure of leukæmic glands or by injury of the duct through sarcoma. The patient was submitted to a course of x ray treatment. The long bones, the spleen, and the glands were exposed to the rays, and the leucocytes fell to 5000 per cubic millimetre after a few weeks. Such cases where the lymphocytes were so abundant were liable to develop malignant disease, mostly of a sarcomatous nature. An interesting property of the pleuritic effusion was that it counteracted the effect produced by adrenalin on the pupil of the eye, whether that of the patient or of an animal. This fact might perhaps in future be made use of to ascertain the nature of doubtful pleuritic effusions.

Cerebro-spinal Meningitis and Deafness.

The epidemic of cerebro-spinal meningitis which occurred in Vienna in 1907 gave Dr. Alt an opportunity of studying its effects on the auditory organs and he recently communicated his results to the Gesellschaft der Aerzte. He examined 60 patients, of whom 9 died without a functional examination being possible. Of the 51 remaining patients 12 became completely deaf, 15 died later, 15 regained full health and hearing, and 9 suffered more or less serious damage. Deafness appeared as an early symptom within the first four days, but in a few cases it came on later; in three cases it supervened after the disease was practically over. The vestibular organs were affected in a high degree. All those who became deaf had an unsteady gait, with vertigo and other disturbances of coördination, until they learned to control their gait through the medium of the other senses, especially that of sight. Microscopic examination of the internal ear constantly showed purulent disease of the labyrinth, the cochlea and the semicircular canals, whilst the nerves were infiltrated and the bony labyrinth was in many cases filled with newly formed connective tissue. The patients who survived and became deaf showed not the least change in the tympanic membrane and functional examination of these patients revealed complete absence of perception of spoken words, musical sounds, or noises, deafness being complete in consequence of the destruction of the inner ear.

Primary Syphilitic Sore of the Nose.

A very rare case of extra-genital syphilis was shown by Dr. Menzel at the same meeting of the above society. The patient was a young man who had for three weeks been complaining of a swelling of the nose. The appearance of the affected part suggested simple abscess or furuncle. Examination of the nares revealed an elliptic, hard, well-defined, prominent nodule, with an ulcer of a lardaceous appearance on the top of it. The infiltration measured about three-quarters of an inch in all diameters. The relative absence of pain, the short duration and the presence of hard indolent glands in the submaxillary region confirmed the diagnosis of specific ulcer. A few days later a typical syphilitic exanthem appeared on the trunk, whilst no trace of any other primary lesion was discoverable. Spirochætæ were found in some of the particles removed for that purpose from the ulcer, so that the diagnosis was unquestionable. Only 25 cases of similar primary infections have been recorded and it was remarkable that nearly all of them were after a short time followed by severe syphilis of the brain; in fact, most dermatologists were agreed that extra-genital syphilis, especially in the head and face, often led very quickly to cerebral lesions. This has been explained by Fournier and Mobl as being due to the fact that in these cases the virulence of the spirochæta was not attenuated as it otherwise was by passing through glands.

Influenza in Vienna.

During the month of December, 1907, and January of the present year, when changes of weather were unusually rapid and frequent, influenza was very prevalent in Vienna, but as a rule the disease ran a very mild course, either because the virulence of the micro-organism was diminished or because the population was already to some extent immunised. The infection was present everywhere and assumed a bronchitic type with complications affecting not only the accessory sinuses of the nose but also the intestinal canal. About 11,000 cases were reported in one week, but the diagnosis was hardly ever confirmed by bacteriological examination. The disease took the shape of a pandemic, all the larger towns in Central Austria suffering alike, so that public offices, schools, and even post-offices had to be closed temporarily. The attack, however, generally passed away in from four to six days.

Feb. 1st.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Rank of Medical Officers in the Navy.

THE resignation of the chief officer of the Bureau of Navigation makes public a controversy in official naval circles in regard to the rank of medical officers in charge of hospital ships. It appears that the head of the Bureau, a rear admiral, contended that these ships should be in command of a line officer and the surgeon should be in charge of the sick only. The Surgeon-General of the Navy endeavoured to have the rule established that a hospital ship should be in command of the surgeon who should have a corresponding rank. A joint board of the army and navy medical officers convened more than a year ago by executive order to unify the medical services as much as possible recommended that hospital ships should be commanded by medical officers, and the recommendation was approved by both the Secretary of War and the Secretary of the Navy in general orders. Accordingly, in the army all hospital ships and medical transports are placed under the Surgeon-General but in the navy the opposition has continued, and in the preparation of the naval medical supplies for the fleet now on the way to the Pacific the question of the position of commander of hospital ships assumed an acute form which was closed by the decision of the President in favour of the Surgeon-General of the Navy and the retirement of the head of the Bureau of Navigation.

Public Medical Lectures.

The Faculty of Harvard Medical College has organised a course of public lectures to be given on Sunday evenings and Saturday afternoons, which are holidays for the working public. The subjects selected for each lecture are of a popular character and are designed to entertain and to instruct the common people. The following are examples: Common Salt; Fatigue, its Effects and Treatment; Alcoholism and Insanity; Infant Feeding; Preventable Diseases of the Skin; and Foods in Health and Disease. The lectures are exciting popular interest and will result in stimulating other medical schools to undertake similar work and thus meet a great public want.

Hospital for Nervous Diseases.

The Department of Charities of New York has established a hospital for the exclusive treatment of diseases of the nervous system on Blackwell's Island. Its capacity is for 250 beds. It is reported that there are more than 1000 patients in the hospitals of the city awaiting admission, all of whom are suffering from various forms of nervous diseases which unfit them for treatment in general hospitals. The new hospital will be equipped with laboratories and all necessary appliances for diagnostic and therapeutic research, and for lectures and demonstrations in neurological science. This is the first hospital of the kind established in this country.

Use of Nostrums by Physicians.

At a meeting of the Philadelphia branch of the American Pharmaceutical Association a discussion arose on the prevalence of the custom of physicians to prescribe advertised nostrums the ingredients of which were unknown. The editor of a leading magazine, which excludes from its columns all nostrums, stated that the present agitation against advertising nostrums had the effect upon the public to make thousands of people absolutely opposed to them. The result is that in three years 18 nostrum manufacturers have gone out of business and two of the largest concerns are for sale. He added that to-day it is practically impossible to get nostrum advertisements into any reputable magazine and within a short time it will be almost impossible to get patent medicine advertisements into the religious weeklies. The next effort is to be centred on the provincial and urban daily newspapers. Dr. H. C. Wood attributed the continuance of the evil of nostrum medication to the leading members of the profession. It appeared on examination of 6000 prescriptions made in the year 1906 that there was 6 per cent. more patent medicine prescribed by leading physicians of Philadelphia than in 1905.

New Board to decide on Pure Food Rules.

Dr. Harvey W. Wiley of the United States Agricultural Department has heretofore made and enforced the rules

Medical News.

UNIVERSITY OF OXFORD.—In a Congregation held on Jan. 23rd the following degrees in medicine and surgery were conferred:—

Bachelors in Medicine and Surgery.—C. G. Douglas, Fellow of St. John's College; G. M. Johnson, Magdalene College; N. Flower, Exeter College; S. Hartill, New College; and B. G. Klein, Corpus Christi College.

—The remaining degree days in the present term are:—Saturday, Feb. 15th, at 2.30 P.M., and Thursday, March 12th, at 10 A.M.

UNIVERSITY OF CAMBRIDGE.—The council of the Senate recommends that the centenary of the birth of Charles Darwin shall be celebrated by the University in the week beginning June 20th, 1909.—The following degrees were conferred on Jan. 30th:—

M.D.—C. J. Coleman, Trinity.
B.C.—C. E. M. Jones, King's; C. Heath, Trinity; A. F. Jackson, Peterhouse; C. H. Treadgold, Clare; and A. W. C. Drake and S. G. Luker, Pembroke.

UNIVERSITY OF LIVERPOOL.—At a meeting of the Senate held on Jan. 29th diplomas in Public Health were awarded to—

E. S. Jones, M.R.C.S., L.R.C.P.; R. C. Mather, M.B., L.R.C.P., L.R.C.S.; and J. Orr, L.R.C.P., L.R.C.S., L.F.P.S.

BRITISH MEDICAL BENEVOLENT FUND.—The annual general meeting of subscribers to the British Medical Benevolent Fund will be held at 15, Wimpole-street, London, W., on Tuesday, Feb. 18th, for the purpose of receiving the treasurer's financial statement and the report of the committee and for the election of a president and other officers and of a committee. The chair will be taken at 5.30 o'clock.

VACCINATION FEES.—At a meeting of the Falmouth board of guardians held on Jan. 29th a letter was read from the Local Government Board stating that the revised scale of fees submitted by the guardians for payment to the public vaccinators was too low. After some discussion it was decided to inform the Local Government Board that the guardians had arranged the fees with the public vaccinators.

MEDICAL INSPECTION OF SCHOOL CHILDREN.—The Thornbury (Gloucestershire) board of guardians at its meeting on Jan. 25th passed a resolution advocating the desirability of the medical inspection of school children being placed in the hands of local medical men instead of appointing a medical officer solely for that purpose.—At a meeting of the Somerset county council held on Jan. 31st it was stated that 68 candidates had applied for the post of chief medical inspector of schools, the salary offered being £500 per annum, with necessary out-of-pocket expenses. Eventually Dr. T. H. Craig Stevenson of Walthamstow was elected.

EXAMINATIONS IN HYGIENE.—A series of examinations in hygiene has been promoted and organised by the Incorporated Institute of Hygiene of London. These examinations will be held at the leading centres throughout England, Scotland, and Ireland, and will include not only the necessary examination showing general proficiency in hygiene but the following additional honours subjects—viz., the hygiene of the home; the hygiene of motherhood; the feeding and rearing of children; food and cooking; home nursing and first aid; school hygiene; and physical training. The future heads of households are those to whom this syllabus more particularly appeals, and there is no doubt that the young women of this country have still much to learn in connexion with personal and domestic hygiene. Nursing and the needs of the invalid and the feeding and rearing of children are subjects which are worthy of being placed in the forefront of a girl's education, as they are likely to be of far more practical use in her daily life than many branches of study which now receive an attention out of proportion to their value. The prevalent ignorance in regard to child-life is one of the chief causes of infant mortality. In personal and domestic hygiene we lag sadly behind some other countries, especially France. It is most important that every school teacher should have a general knowledge of the principles of hygiene, quite apart from the special knowledge required in teaching it. An examining board, composed of some of the leading physicians and men of science throughout the country, has been formed to further this branch of the educational work of the Institute of Hygiene; and every assistance and encouragement will be given to candidates who may carry on their studies at school, college, or at home, while they will receive the certificate of the institute for proficiency in elementary knowledge and the diploma of the institute for proficiency in advanced knowledge should they pass the examination successfully. Further particulars can be obtained from the Secretary, Incorporated Institute of Hygiene, 34, Devonshire-street, Harley-street, London, W.

THE ROYAL SANITARY INSTITUTE.—A provincial sessional meeting of the institute will be held at the Council Chamber, Exchange Buildings, Nottingham, on Saturday, Feb. 15th, when a discussion will take place on "Present-day Road Requirements in Town and Country." The discussion will be opened by Mr. E. Purnell Hooley, M.Inst.C.E., county surveyor, Notts, to be followed by, amongst others, Mr. A. Brown, M.Inst.C.E., city engineer, Nottingham, and Dr. F. R. Mutch, chairman of the health committee, and a general discussion is invited. The chair will be taken at 11 A.M. by Mr. H. D. Searles-Wood, F.R.I.B.A., chairman of the council of the institute. Tickets for admission of visitors may be had on application to Dr. P. Boobbyer, medical officer of health, Guildhall, Nottingham, who is acting as the local honorary secretary of the meeting; and of Mr. E. White Wallis, secretary, Parkes Museum, Margaret-street, London, W.

LITERARY INTELLIGENCE.—Messrs. J. and A. Churchill are just about to publish the second and concluding volume of "The Labyrinth of Animals," by Dr. Albert A. Gray, aural surgeon to the Victoria Infirmary, Glasgow; the work will be illustrated by stereoscopic plates. Another new book to be published by the same firm is entitled "Abdominal Tuberculosis," by Mr. A. E. Maylard; the text will be illustrated. New editions nearly ready are the second of "Lectures on Medical Jurisprudence and Toxicology," by Dr. F. J. Smith of the London Hospital; additional lectures on "The Examination of the Person Alive and Dead," "Anæsthetics," and "Death Certification" have been included; also the sixth edition of "A Simple Method of Water Analysis," by Dr. J. C. Thresh of the London Hospital.—A branch of the London Independent Labour Party, viz., the Committee for Promoting the Physical Welfare of Children, has issued a pamphlet by Mr. M. D. Eder on "Diseases in the Schoolroom," in which the writer points out how urgent the need is for attention to the many diseases now prevalent in the State schools. The pamphlet is published at the nominal price of *1d.* and aims at helping the efficacious carrying out of the Act which came into force on Jan. 1st for the medical inspection of school children.

THE ELEVENTH INTERNATIONAL CONGRESS OF OPHTHALMOLOGY.—This congress will meet at Naples at the beginning of April, 1909, and its organising committee has already issued a circular letter of invitation. Professor Marc Dufour will be honorary president and Dr. Landolt will be vice-president. The corresponding members of the congress for Great Britain are Mr. Walter H. H. Jessop, 73, Harley-street, London, W.; Professor George Mackay, 20, Drumsheugh-gardens, Edinburgh; and Sir Henry R Swanzy, 23, Merrion-square, Dublin. Ophthalmologists subscribing to the congress and wishing to communicate papers must forward their titles during the September of this year. All papers must be compiled in one of the official languages of the congress—viz., Italian, French, English, German, and Spanish. Documents will be sent before the meeting to those who shall have signified their intention to be present and will contain the information relating to the work of the commission nominated at the preceding congress to consider the themes of discussion: First, to fix, with regard to an indemnity, the value of a lost or damaged eye; and, secondly, unification of the measure of the visual power and unification of the notation of the meridians of astigmatism. The subscription for the congress is 25 francs for members and 10 francs for every member of their family. Notification of presence, subscriptions, and communications relating to the congress should be addressed directly to Professor Arnaldo Angelucci, R. Clinica Oculistica in S. Andrea delle Dame, Naples, or to one of the corresponding members of the respective countries. The member's ticket which those taking part at the congress will strong bar appeared on both sides. The jury found generally for the defendants and Mr. Justice Cussen said that he would appoint a future day to hear arguments as to how the verdict should be entered and as to costs. On a subsequent application judgment was entered for the defendants with costs upon one count, and as to the other count a new trial was ordered.

Diphtheria Patient Fined.

An unusual prosecution in this part of the world was made in the case of a woman who was charged under the Health Act that she was, while knowing she was suffering from a dangerous infectious disease—to wit, diphtheria—intentionally in a public place. The patient had been an inmate of the infectious diseases hospital and though convalescent left the institution against the order of the medical superintendent. In going home to her family she called at a friend's house and sat on the verandah. The magistrates imposed a fine of 10*s.* with £3 3*s.* costs.

State Relief.

The annual report of the State Children's Relief Board of New South Wales shows that 7049 children are under supervision, 4024 being boarded out apart from, and 3025 with, their mothers. The expenditure for the entire service of the department was £69,772. Contributions of parents amounted to £2078, leaving the actual cost to the State of each child at £15 6*s.* Allowances to widows and deserted wives towards the support of their children at home amounted to £19,269, so that the State appears to be assuming a large undertaking in addition to education. 1201 children are apprenticed under the control of the Board. Their wages are paid into the Savings Bank and disbursed according to a scheme that has worked well, two-thirds being retained till the child is 21 years old. Street-trading licences were issued to 735 children.

British Medical Association.

The annual meeting of the Victorian branch of the British Medical Association was held on Dec. 3rd. The retiring president (Professor H. B. Allen) delivered an address in which he outlined the scheme by which the branch had become amalgamated with the Medical Society of Victoria. The following office-bearers were elected for 1908: President, Mr. G. A. Syme; Vice-Presidents, Dr. R. R. Stawell and Mr. G. Cuscaden; Secretaries, Dr. L. J. Balfour and Dr. Henry Laurie; Treasurer, Dr. O. H. Mollison; Librarians, Mr. A. W. F. Noyes and Dr. H. D. Stephens; Council, Dr. W. R. Boyd, Dr. Felix H. Meyer, Dr. W. Moore, Mr. F. W. Morton, Dr. A. Lewers, Mr. W. Beattie-Smith, Dr. A. J. Wood, and Dr. G. T. Howard.

Dec. 28th, 1907.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Bradycardia in Appendicitis in Children.

Dr. János Bókay, professor of pædiatrics at the University of Budapest, has drawn attention in a clinical lecture to the importance of bradycardia in children suffering from appendicitis. This symptom has not been dealt with as yet; in the literature of the subject there is only one memoir referring to bradycardia in appendicitis, and in it only adults are considered. Professor Bókay draws the following conclusions from an experience of ten cases treated successfully. 1. During the absorption of the periappendicular exudation bradycardia sets in almost regularly and persists for many days; it may even last for more than a fortnight. 2. Bradycardia may also be observed after an appendicular abscess has been evacuated by an operation. 3. In children between the ages of seven and 16 years the pulse-rate ranged from 52 to 80. 4. There is no parallelism whatever between the pulse-rate and the temperature. 5. Bradycardia cannot be regarded as an unfavourable sign from the point of view of prognosis; on the contrary, in cases of periappendicular exudation it is a sign of the commencement of the process of absorption. In all the ten cases observed by Professor Bókay the bradycardia must have been of extracardial, i.e., nervous, origin, because organic heart disease could be excluded. He was therefore justified in assuming that the essential cause was irritation of the vagus, probably due to the absorption of toxins from the periappendicular exudation.

Why do not the Living Stomach and Intestine Digest Themselves.

Dr. Nandor Klug, professor of physiology, has been investigating in his laboratory the still unsolved question, why the living stomach does not digest itself. His investigations were based on Weinland's experimental results, according to which the walls of the stomach and intestines defend themselves against the proteolytic enzymes by means of anti-enzymes or anti-ferments. Professor Klug has found that the inner half of the gastric mucous membrane contained a substance which powerfully resisted the digestive action of the trypsin and the gastric juice. The stomach (and the small intestines as well) were therefore protected against self-digestion by mucin which they themselves secreted. Dr. Klug's experiments did not prove the presence of so-called anti-ferments, as supposed by Weinland. The mucin could not be digested either by the mixture of pepsin and hydrochloric acid or by the trypsin solution. Mucin was not liable to diffusion; it retained the trypsin and pepsin, and this property sufficed for the protection of the stomach and intestines from self-digestion. The ascaris lumbricoides was not digested by the intestinal fluids on account of the resistant properties of its external covering.

Cancer of the Lip.

At a recent meeting of the Budapest Medical Society Dr. Heiner Pál read a paper giving statistical details of the cases of cancer of the lip which have been under observation in Professor Dollinger's clinic during the last seven years. He said that labial cancer was ten times as frequent in men as in women and that cancer of the lower lip was twelve times as frequent as that of the upper lip. All parts of the lower lip were alike liable to be attacked; in the upper lip, on the other hand, the favourite site of the disease was the middle part. Cancer of the lip was most frequent in agricultural labourers and men who smoked pipes. It mostly occurred between the ages of 55 and 60 years. Preceding inflammations, psoriasis, leukoplakia, and scars had an important influence in the development of the disease. With regard to the period of admission to hospital, 84 per cent. of the patients presented themselves within the first year from the onset of the cancer and in 76 per cent. of the cases the parts were already ulcerated. In 67 per cent. of the cases there was a regional glandular infiltration present. Of the cases operated on, 69·6 per cent. have now remained free from recurrence for over five years. In two-thirds of the cases in which there has been recurrence death supervened in the course of the first year.

The Position of the Assistant Medical Officers of the Budapest Hospitals.

On Jan. 28th the assistant medical officers of the Budapest municipal hospitals—namely, St. Rochus, St. Ladislaus, St. Stephen, the Workhouse Hospital, St. John and Margareth Hospitals—gave notice to the director, Professor Kolomann Müller, that they would resign their posts on Feb. 4th. The motive for taking this step is the lowness of the salaries paid to the assistant medical officers. In 1904 they asked the municipal board to raise their remuneration from 1200 kronen (£50) to 2000 kronen, considering the great amount of work which they have to do and the expensiveness of living in Budapest. They pointed out that an assistant medical officer has to attend 200 patients daily and that the duties as well as the present salaries were fixed many years ago at a time when x ray work, advanced bacteriology, and the manifold forms of physical treatment now in use did not exist. It could therefore be easily understood that they have to work hard from early morning till late in the evening. They hoped that the municipal board would comply with their request, but on Jan. 27th the board refused the application. The assistant medical officers accordingly gave notice of their intention to resign their posts. The medical profession in general sympathises with them and is ready to offer help and support if the board maintains its present attitude.

Jan. 28th.

ST. MARY'S HOSPITAL.—A new special department for nervous diseases has been instituted in the out-patient practice of this hospital; it is a development of the electro-therapeutic department and will receive new cases as such, instead of only dealing with cases referred to it from other departments. The x ray department remains separate as before. Dr. Wilfred Harris has been appointed physician-in-charge of the department for nervous diseases in addition to his duties as senior physician to out-patients.

to the increase in the number of courses of lectures and the flourishing conditions of the teaching department, students being attracted from all parts of the world. The health of the chairman was proposed by Mr. R. Marcus Gunn, senior surgeon to the hospital.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Opening of Parliament.

Parliament was opened with the usual State ceremonial by His Majesty the King on Wednesday, Jan. 29th. Amongst the measures which were promised in the speech from the Throne were Bills to amend the Acts relating to the housing of the working classes and to regulate the laying out of land needed for the development of growing urban centres; to improve and extend university education in Ireland, and to consolidate and to amend the law relating to the protection of children and to the treatment of juvenile offenders.

The Pharmacy (Ireland) Acts.

An order approving of a regulation made under the Pharmacy (Ireland) Acts by the Pharmaceutical Society of Ireland has been ordered to lie upon the table of both Houses of Parliament.

New Bills.

Since the Session began the following Bills have been introduced into the House of Commons: The Sweated Industries Bill, by Mr. Toulmin; the Housing of the Working Classes (Ireland) Bill, by Mr. Hagan; the Education (Provision of Meals) (Scotland) Bill, by Mr. T. F. Richards; the Coroners' Inquests (Railways Fatalities) Bill by Sir Francis Channing; the Coroners' Inquests Bill, by Mr. Higham; and the Infant Life Protection Bill by Mr. Staveley-Hill. Several of these measures have been before the House on previous occasions. Mr. Higham's measure is designed to dispense with the compulsory viewing of bodies on the holding of coroners' inquests.

Legislation on Milk-Supply.

It is the intention of the Earl of Northbrook to put a question to the Government in the House of Lords next week with respect to legislation with regard to milk-supply. Mr. Burns, however, has intimated in the House of Commons that it is the intention of the Government to promote a Bill on the subject during the session.

Alcohol and Tuberculosis in Ireland.

On the motion of Mr. Sloan, the House of Commons has ordered a return giving statistics showing the number of deaths in Ireland due to alcohol and tuberculosis for the 12 months ending on the 31st day of December, 1907.

HOUSE OF LORDS.

Wednesday, Jan. 29th.

The International Conference on Sleeping Sickness.

Answering a question put by the Earl of Mayo in the course of the debate on the Address, Lord Fitzmaurice, the Under Secretary for Foreign Affairs, said that the International Conference upon Sleeping Sickness and Tropical Disease, which met at London, arrived at certain conclusions, but as the delegates who came from various foreign States had no power to sign a treaty the Conference adjourned. It was hoped that the Conference would reassemble in March and that then a convention would be signed.

HOUSE OF COMMONS.

Friday, Jan. 31st.

Medical Appointments in India.

Dr. V. H. Rutherford in the course of a speech advocating changes in the method of governing India, incidentally observed that the natives of that country could not get the high appointments in the medical profession there. All the best appointments in the hospitals and medical colleges were kept in the hands of Europeans.

Monday, Feb. 3rd.

Children in Public-houses.

Mr. Wedgwood asked the Secretary of State for the Home Department whether his attention had been drawn to the statement of the Chief Constable of Liverpool that the action of the Liverpool Licensing Bench in discountenancing the presence of children in public-houses was responsible for the fact that the children observed to be taken into public-houses in Liverpool amounted to only 1·25 per public-house per hour against 9·12 in London; and whether the same method of checking this evil could be recommended by the Home Office to other licensing benches.—Mr. H. Samuel (who replied) said: The Secretary of State does not find that the Chief Constable of Liverpool committed himself to so definite a statement as my honourable friend attributes to him, but there can be no doubt that the views of a licensing authority on the question of the admission of women and children into public-houses must have a strong influence on the licence-holders within their district. The Secretary of State has no power to advise licensing authorities in this matter, but he is sure that they must all be fully alive to a question which is so much in the public mind at the moment and which will be dealt with in coming legislation.

Tuesday, Feb. 4th.

The Sleeping Sickness.

Mr. Rees asked the Under Secretary of State for the Colonies what measures had been taken to prevent the spread of sleeping sickness from Uganda towards Nyassaland.—Mr. Churchill answered: The question of the spread of sleeping sickness towards Nyassaland is being investigated by a party of scientific experts sent out by the Liverpool School of Tropical Medicine with the assistance of a grant from Government funds. When their report has been received the Secretary of State will consider in consultation with the Governor of the Protectorate what measures, if any, are required. The whole matter is being closely watched.

Regulations on Imported Meat.

Mr. Courthope asked the President of the Local Government Board what steps, if any, were being taken to remove the danger to the public health arising from imported meat and to carry out the recommendations contained in Dr. G. S. Buchanan's recent report on the subject.—Mr. Burns replied: I have caused regulations to be prepared under the Public Health (Regulations as to Food) Act of last session dealing with the subjects referred to in Dr. Buchanan's report, and I am now in communication with the other departments concerned with regard to them.

Milk-supply and Legislation.

Mr. Victor Cavendish asked the Prime Minister whether, in view of the widespread anxiety existing in many parts of the country, he would cause a full inquiry to be made into the question of the supply of milk in relation to public health before any legislation was introduced.—Mr. Burns (who replied to the question) said: The Government is desirous that there should be legislation with regard to milk-supply during the present session, and I could not promise further inquiry before introducing a Bill on the subject.

Irish Poor-law Medical Officers.

Mr. Fetherstonhaugh asked the Chief Secretary to the Lord Lieutenant of Ireland whether it was intended to introduce any legislation during the present session to give effect to the report of the Commission on the Irish Poor-law Administration, and in particular to deal with the grievances of the Irish Poor-law medical officers.—Mr. Birrell answered: It is the intention of the Government to introduce legislation to amend the Irish Poor-laws, but I cannot hold out any hope that an opportunity will arise during the current session.

Wednesday, Feb. 5th.

A Tuberculosis Prevention Bill for Ireland.

Mr. Augustine Roche asked the Chief Secretary to the Lord Lieutenant of Ireland whether, in view of the unanimous expression of public opinion all over Ireland during the past six months on the urgent necessity of taking steps to check the ravages of consumption in Ireland, any action would be taken this session to amend the law in conformity with the views expressed at the meetings.—Mr. Birrell replied: It is intended to introduce a Bill on the subject referred to in the question. The Bill, which has been drafted, is entitled "The Tuberculosis Prevention (Ireland) Bill, 1908." I hope it will pass into law during the present session.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Bailey, T. Ridley, M.D. Edin., has been appointed School Medical Officer under the Bilston Education Committee.

Bird, W. E. F., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer to the York Post Office.

Charles, Herbert, M.R.C.S., L.R.C.P. Lond., has been appointed Anæsthetist to the Paddington Green Children's Hospital.

Collier, James, M.D., F.R.C.P. Lond., has been appointed Physician in Charge of Wards to St. George's Hospital.

Edington, G. H., M.D. Edin., F.F.P.S. Glasg., has been appointed Assistant to the Professor of Clinical Surgery, University of Glasgow.

Jardine, Robert, M.D. Edin., M.R.C.S. Eng., F.F.P.S. Glasg., F.R.S.E., has been appointed External Examiner in Obstetrics to the Victoria University, Manchester.

Maynard, Edwin, F.R.C.S. Eng., L.R.C.P., D.P.H. Lond., has been appointed Senior House Surgeon at the Bristol General Hospital.

Mudge, Zachary Belling, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health for the Hayle (Cornwall) Urban District Council.

Naylor, Rupert George St. John, F.R.C.S. Edin., has been appointed Public Vaccinator for the South-Eastern District of Victoria, Australia.

Sleeman, James Henry, M.B., Ch.B. Melb., has been appointed Public Vaccinator for the South-Western District of Victoria, Australia.

Stevenson, Thomas Henry Craig, M.D., B.S. Lond., L.R.C.P. Lond., M.R.C.S., D.P.H. Cantab., has been appointed Chief Medical Inspector of Schools by the Somerset County Council.

Thomas, Frank Leslie, M.B., B.S. Lond., M.R.C.S., L.R.C.P. Lond., has been appointed *pro tem.* District Medical Officer by the Barnstaple Board of Guardians.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Abertillery Urban District Council. Education Committee.—Doctor (female). Salary at rate of £150, rising to £200 per annum.

Acton Urban District Education Committee.—Medical Inspector of Schools (female). Salary £200 per annum.

Bangor, Carnarvonshire and Anglesey Infirmary.—House Surgeon. Salary £80 per annum, with board, lodging and washing.

Bath, Royal Mineral Water Hospital.—Resident Medical Officer. Salary £100 per annum, with lodging, board, and laundry.

SIR THOMAS McCALL ANDERSON, M.D. GLASG., F.F.P.S. GLASG.,
REGIUS PROFESSOR OF MEDICINE IN THE UNIVERSITY OF GLASGOW.

allowed the muffin-bell to become a familiar, but unnecessary, form of nuisance, only to take steps against it upon its disturbing the slumbers of members of "the force." Nevertheless, if we are to witness the total disappearance of the muffin-man as a result of his being unable to advertise his wares in the accepted manner of doing so we may temper our sympathy with the individual by the reflection that he distributed articles of diet of doubtful origin in a manner which few could regard as desirable. His tray often covered with a piece of baize of a hue suggestive of long service in the murky atmosphere of the London streets has not been an ideal means of conveyance from a sanitary point of view, nor has his personal cleanliness been always above criticism.

A MEDICAL correspondent writes under the signature "Phenad": "Can anyone give me information as to any localised poisonous possibilities from a leech-bite, as distinct from an infection of the wound left by the bite?"

◆

P. A. F.—We have read most of the stories before. These people thrive on contradiction, while nothing minimises the mischief of their action so much as never to mention them.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Ormond-street (2.30 P.M.), Tottenham (Gynæcological, 2.30 P.M.)

FRIDAY (14th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.).

SATURDAY (15th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, *Hanover-square, W.*

TUESDAY.—(*Surgical Section*). 5.30 P.M., Mr. A. H. Tubby: Co Valga

THURSDAY.—(*Obstetrical and Gynæcological Section*). 7.45 P.M. The President, Dr Macnaughton-Jones, Dr. E. Holland, an Dr. A. Routh: Specimens. Dr. R. Andrews and Dr. Maxwell; A Case of Difficult Labour, with Remarks on th Specimen of the Frozen Section of the Uterus. Dr. M. Randal An Ovarian Dermoid with Secondary Cysts connected with th Omentum, with Pathological Report and Remarks by M T. W. P. Lawrence.

FRIDAY.—(*Clinical Section*). 8.30 P.M., Dr. L. Guthrie and Mr. Mayou Mr. J. P. Roughton, Dr. H. French, Mr. R. J Godle, Dr. S. Taylor, Dr. A. Latham, and Dr. F. P. Weber: Exhibition of Cases. Dr F. G. Batten and Dr. J. G. Forbes: Note on a Case of Gaertner Infection in an Infant. The patients will be in attendance at 8 P.M.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Clinical Evening. Mr. G. Watson, Dr. Wynter, Dr. M. Dockrell, Dr. R. Hutchison, Dr. W. H. Willcox, Dr. de H. Hall, Dr. A. Morison, Dr. C. Wall, and *others*: Cases

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM, 11, Chandos-street, Cavendish-square, W.

THURSDAY.—8 P.M., Clinical Evening. Mr. L. Paton, Mr. J. Hosford, Dr. F. W. Edridge-Green, Mr. J. H. Fisher, and others: Cases and Demonstrations. 9 P.M., Discussion of th Cases.

UNITED SERVICES MEDICAL SOCIETY, Royal Army Medical College, Millbank, S.W.

THURSDAY.—8.30 P.M., Dr. Pembrey: The Physiological Principles of Physical Training.

MEDICO-LEGAL SOCIETY, 22, Albemarle-street, W.

TUESDAY.—8.15 P.M., Narration of Cases and Exhibits of Medico-Legal Interest. Dr. L. Freyberger: An Analysis of 14 Cases of Sudden Death while under the Influence of an Anæsthetic.

HARVEIAN SOCIETY OF LONDON, Stafford Rooms, Tichborne-street, Edgware road, W.

THURSDAY.—8.30 P.M., Mr. M. Smith: The Diagnosis and Treatment of Abdominal Injuries. Dr. C. Jones: The Treatment of Bronchial Asthma by Inoculation with a Bacterial Vaccine.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MONDAY.—5 P.M., Mr. S. G Shattock: Ovarian Teratomata.

WEDNESDAY.—5 P.M., Dr. J. W. H. Eyre: The Importance (Surgically) of the Pyogenetic Activities of Diplococcus Pneumoniæ.

FRIDAY.—5 P.M., Mr. L. S Dudgeon: Infection of the Urinary Tract due to Bacillus Coli.

(Erasmus Wilson Lectures.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. A. Whitfield: Clinique (Skin). 5.15 P.M. Lecture:—Dr. P Stewart: Thalamic Hemiplegia.

TUESDAY.—4 P.M., Dr. A. Morison: Clinique (Medical). 5.15 P.M. Dr. M. Dobbie: Swedish Medical Gymnastics, their App in the Treatment of Diseases of the Circulatory and Systems.

WEDNESDAY.—4 P.M., Mr. H. L. Barnard: Clinique: 5.15 P.M., Lecture:—Mr. R. H. J. Swan: Carcinoma of Breast, its Early Recognition and Treatment.

THURSDAY.—4 P.M., Clinique (Surgical). 5.15 P.M., Lecture:—D J. E. Squire: Pneumothorax.

FRIDAY.—4 P.M., Dr. StClair Thomson: Clinique (Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith road, W.

MONDAY.—12 noon: Lecture:—Dr. Low: Pathological. 2 P.M. Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M., Operations. 5 P.M., Lecture:— Davis: Clinical.

TUESDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 12 noon: Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M. Medical and Surgical Clinics. X Rays. Dr. Ball: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Moullin: Gynæcological Cases.

WEDNESDAY.—10 A.M., Dr. Ball: Diseases of the Throat, Nose, Ear. Dr. Saunders: Diseases of Children. 2 P.M., Medical Surgical Clinics. X Rays. Dr. Scott: Diseases of the 2.30 P.M., Operations. 5 P.M., Lecture:—Mr. Pardoe: Cystitis

THURSDAY.—12 noon, Lecture:—Dr. Pritchard: Practical Medicine 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Diseases of the Eye. 2.30 P.M., Operations. 5 P.M., L Mr. Baldwin: Practical Surgery.

FRIDAY.—10 A.M., Dr. M. Moullin: Gynæcological Operations 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Diseases of the Throat, Nose, and Ear. 2.30 P.M., Opera Dr. Abraham: Diseases of the Skin. 3 P.M., Lecture:— R. Jones: Types of Insanity (at the London County Asylum Claybury, Woodford Bridge, Essex).

SATURDAY.—10 A.M., Dr. Ball: Diseases of the Throat, Nose, Ear. Dr. Saunders: Diseases of Children. 2 P.M., Medical Surgical Clinics. X Rays. Dr. Scott: Diseases of the 2.30 P.M., Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—*Cliniques*:—10 A.M., Surgical Out-patient (Mr. Evans). 2.30 P.M., Medical Out-patient (Dr. T. R. Throat, Nose, and Ear (Mr. H. W. Carson); X Ray (Dr. Pirie). 4.30 P.M., Medical In-patient (Dr. A. J. Whiting).

founding the Glasgow Hospital and Dispensary for Diseases of the Skin. In this institution he worked hard all his life and obtained a wide experience of all varieties of cutaneous maladies. His annual clinique on diseases of the skin has done much to promote a thorough knowledge of dermatology amongst the practitioners graduating from the Glasgow school. During his busy life Sir Thomas McCall Anderson found time also to contribute largely to the literature of medicine. His largest work, as has already been mentioned, was the "Treatise on Diseases of the Skin." Among the long list the following may also be mentioned: "On the Curability of Attacks of Tubercular Peritonitis and Acute Phthisis (Galloping Consumption)"; on "Syphilitic Affections of the Nervous System: their Diagnosis and Treatment"; and "Lectures on Clinical Medicine delivered in the Royal and Western Infirmaries of Glasgow." These, and we might mention many more, are sufficient to show the wide scope of his literary efforts and of his clinical studies. As a writer his style was clear and terse; and his views both on diagnosis and treatment were always based upon cases actually observed and treated. As a man of affairs he had a high reputation. He was a good business man; and his sound common-sense was recognised by his being placed on a number of public and charitable boards. In politics he was a Conservative and he took an interest in the local affairs of the party. For many years he was an elder in the Church of Scotland.

In 1900 Sir Thomas McCall Anderson was transferred by Lord Balfour of Burleigh, then Secretary for Scotland, to the chair of Practice of Medicine vacated by Sir William T. Gairdner. In 1903 he succeeded the same gentleman as representative of the University of Glasgow on the General Medical Council. He was knighted in 1905 and two years later, on the death of Sir William Gairdner, he succeeded him as one of the honorary physicians to the King in Scotland. He has now ended his busy life full of honours, having discharged his daily duties to the very last. On the Monday after his death the headings of his intended lecture for that day on cerebral hæmorrhage were found written in his own hand on the blackboard of his class-room. His punctuality and diligence in his medical work have long been admired by his medical brethren; and those who were his students will not soon forget the clear and succinct clinical teaching which in the case of many of them laid the foundation of their own success in the profession of medicine.

He is survived by Lady McCall Anderson, one son, and five daughters, with whom much sympathy is felt.

JAMES BELL PETTIGREW, M.D. EDIN., F.R.C.P. EDIN., F.R.S. LOND., LL.D. GLASG.,

PROFESSOR OF MEDICINE AND ANATOMY IN THE UNIVERSITY OF ST. ANDREWS.

Professor James Bell Pettigrew died at his residence, The Swallowgate, St. Andrews, on Jan. 30th, after a long illness. He was born in 1834 at Roxhill in Lanarkshire, and was related on his mother's side to Henry Bell, the founder of steam navigation in Europe. He studied medicine in the University of Edinburgh, where he graduated as M.D. in 1861, receiving a gold medal for his thesis; he was also a gold medallist in the subjects of anatomy and medical jurisprudence. From 1862 to 1868 he held the appointment of assistant curator at the Hunterian Museum of the Royal College of Surgeons of England. Returning to Edinburgh he worked for the Royal College of Surgeons in that city, being appointed curator of the museum in 1869 and lecturer on physiology in 1873. In 1875 he became Chandos professor of medicine and anatomy in the University of St. Andrews, a position which he held till the time of his death, although increasing infirmities compelled him not long ago to relinquish the active duties connected with his chair. Professor Pettigrew made many valuable contributions to medical literature, chiefly in the form of articles published in various journals and papers read before societies. At an early part of his career he worked at the muscular structure of the heart, stomach, and bladder; and some of his results were published in the *Philosophical Transactions* in 1864 and 1867. The latter of these two memoirs gained for him in 1874 the Godard prize of the French Academy of Sciences and he also received the distinction of laureate of the Institute of France. He subsequently gave much attention to problems connected with the flight of birds. In 1873 he published a treatise on "Animal Locomotion," and the article entitled "Flight: Natural and Artificial," in the ninth edition of the "Encyclopædia Britannica" (1879) was written by him. Various forms of flying machines were devised by him for the purpose of illustrating his views. On Nov. 23rd and 30th, 1901, we published two valuable papers by him on the making of anatomical preparations, and again in January, 1904, an article on Spiral Fomrations in Relation to Walking, Swimming, and Flying. Marrying in 1890, Professor Pettigrew has left a widow who was a daughter, of the late Sir W. Gray of Greatham, Durham.

CHARLES JAMES WRIGHT, M.Sc. LEEDS, M.R.C.S. ENG.,

EMERITUS PROFESSOR OF OBSTETRICS, UNIVERSITY OF LEEDS; HONORARY CONSULTING SURGEON TO THE HOSPITAL FOR WOMEN AND CHILDREN, LEEDS.

THE loss which Leeds has sustained by the death of Mr. O. J. Wright will be felt not only by those with whom he has for so many years been associated but by a large number of medical men in practice in various parts of the county of York and elsewhere. Though Mr. Wright had been manifestly failing in health for some years he went on bravely with his work until about a week before he passed away on Jan. 17th, and the announcement of his death came as a surprise even to many of his friends in Leeds. Mr. Wright, who was in his sixty-sixth year, was a native of Wakefield. He was educated at St. Peter's School, York, and was a student of the old Leeds School of Medicine as well as of Guy's Hospital. It may be said that the whole of his professional life was identified with the Leeds School of Medicine, for as a student he worked in the old house in East Parade, and in this house he also taught. He was associated with the school when it was housed in the new premises in Park-street, opened by Sir James Paget, and he continued his work until last year in the new buildings opened by the present Prince of Wales in the early "nineties." To few men indeed is it given to be a member of the active teaching staff of any institution for the long period of 41 years, and not only was this the case with Mr. Wright, but everyone who was acquainted with his work will cordially agree that during the whole of that time his energies were unsparingly devoted to the welfare and reputation of the school. Mr. Wright's earlier work was done in the departments of anatomy and physiology but from the year 1884 he was responsible for the teaching of obstetrics, first as lecturer in succession to the late Mr. William Nicholson Price, and subsequently to 1888 as professor. The University honoured him by conferring upon him the degree of Master of Science and on his resignation of the professorship last year it will be remembered that he was promoted to the honorary position of emeritus professor.

For many years Mr. Wright was a member of the honorary staff of the Hospital for Women and Children. On retiring from the active staff last year he was elected honorary consulting surgeon to the institution. In the reconstruction of this charity and in the erection of the new buildings, which were opened a few years ago, he took a very active part. For many years he was connected with the important work of the Leeds District Nursing Association and the committee will for long look back with gratitude to his genial and unsparing solicitude for the welfare of the nurses, at whose disposal he always held himself in times of illness. Though always in general practice Mr. Wright devoted himself more especially to obstetrics and gynæcology and he was frequently called in consultation by his former students in cases of difficulty. A distinguishing characteristic of Mr. Wright was his extraordinary grasp of details; he was apparently able at any time to lay his hand on some memorandum of an event which everyone else was at a loss to give a clear account of. One of his colleagues described him as "a born secretary," and another in joke said "his house must be full of pigeon holes," so unfailing was his accuracy in this respect. With this he combined a geniality of manner and a true kindness of heart which those who came much in contact with him will never forget. He probably valued nothing so much as the esteem and gratitude of his students, and this he had in a measure which was alike an honour to them and to him on whom it was bestowed. The sympathy of all who knew him will be freely extended to Mrs. Wright and his family, and his colleagues will always keep his memory fresh in their minds as of one who did his duty manfully.

Communications, Letters, &c., have been received from—

A.—Acton Urban District Council, Clerk to the; Ancoats Hospital, Manchester, Secretary of; Dr. F. H. Alderson, Bournemouth; Anglo-American Pharmaceutical Co., Croydon.

B.—Sir John W. Byers, Belfast; Bath Royal United Hospital, Secretary of; Messrs. Bale, Sons, and Danielsson, Lond.; Bristol Royal Infirmary, Secretary of; Mr. F. D. Byrne, Lond.; Miss C. S. Bremner, Lond.; Mr. J. C. H. Beaumont, Plymouth; Mr. Frank Birch, Lond.; Dr. Alexander Brown, Lond.; Dr. G. P. Blacker, Lond.; Mr. J. L. Baskin, Salisbury; Messrs. S. W. Bush and Son, Bath; Mr. J. Bell, Hong-Kong; Dr. W. Bulloch, Lond.; Bayer Co., Lond.; Messrs. S. W. Bush and Son, Bath; Mr. F. Burgis, Buenos Aires; British Medical Benevolent Fund, Lond., Hon. Secretary of.

receive is strictly personal and available for no one else. It will also give free entrance to the museums and to public buildings as well and entitle its holder to reductions from the railways and to other privileges which will be indicated later.

DONATIONS AND BEQUESTS.—Under the will of Colonel Edward Sanderson Tozer, V D., of Sheffield, the Sheffield Royal Infirmary. the Sheffield Royal Hospital, and the Jessop Hospital for Women will each benefit by a legacy of £500.—By the will of Major Christopher Deake Brickmann of Bath £200 have been left to the Eastern Dispensary, Bath, and £500 to the Royal United Hospital, Bath, for the maintenance of a cot to be called after the testator.

THE After-Care Association for poor persons discharged as recovered from asylums for the insane held its annual meeting on Jan. 29th, at 48, Wimpole-street, London. Mr. Anthony Hope Hawkins was in the chair. The report of the council read by the secretary, Mr. H. T. Roxby, stated that the proportion of cases successfully treated had been very encouraging. The results showed that the prevention of relapse into insanity was possible when an efficient re-start in life was given. Many persons discharged from asylums for the insane were quite capable of work if suitable occupation were found for them, but were unable to stand the anxiety and strain of procuring it for themselves. The council wished to call particular attention to this point as it was often overlooked when patients were discharged and their slender means were spent before they applied for help from the Association at the Church House, Dean's-yard, Westminster. Amongst those present were Dr. G. H. Savage who spoke on the difficulties of convalescence from mental disorders, Dr. G. F. Blandford, Dr. G. Amsden, and Dr. H. Bond.

THE WEST AFRICAN MEDICAL STAFF.—The winter dinner of the West African Medical Staff took place on Jan. 29th, at the New Gaiety Restaurant, Strand, London. There was a large attendance of members, including Dr. W. T. Prout, C.M.G., of the Liverpool School of Tropical Medicine, late principal medical officer, Sierra Leone, who presided; Mr. G. J. Rutherford, senior medical officer, Gold Coast; Dr. C. R. Chichester, senior medical officer, Northern Nigeria; Dr. M. Cameron Blair, senior medical officer, Southern Nigeria, and others. Among the guests were Sir Patrick Manson, K.C.M.G., Mr. J. Robinson of the Colonial Office, and Dr. C. W. Daniels of the London School of Tropical Medicine. Letters regretting inability to be present were received from Mr. R. Antrobus, C.B., Assistant Under Secretary of State for the Colonies, Sir Alfred Jones, K.C.M.G., Sir Rubert Boyce, and others. Dr. Prout, in proposing "Success and Prosperity to the West African Medical Staff," said that he was sure that in the midst of these luxurious surroundings those present would remember their brother officers who were bearing the white man's burden in the unhealthy wilds of West Africa. He then briefly reviewed the changes which had come about since he first went out to West Africa and drew attention to the vast developments which had taken place in tropical science of late years, many of which were due to the ability, the dogged determination, and the far-sightedness of that veteran of tropical medicine whom they were proud to have as an honoured guest that evening, Sir Patrick Manson. But up to the present there had been one thing lacking—the feeling of comradeship and *esprit de corps* which was so essential to the welfare of any body of men, scientific or otherwise, who are bound together by a common training, common knowledge, and common interests. This was possibly due mainly to the geographical conditions of West Africa and he believed that these dinners would do much to foster that feeling of union and cohesion which was so necessary. It was his conviction that whatever was conducive to the efficiency of the medical staff would undoubtedly be for the benefit of the general community who lived under the unhealthy conditions of West Africa, and he was sure that he was speaking for all of them when he said that they would welcome any improvement of this nature, not for merely selfish and personal considerations, but because of the great gain to health and sanitation which would result. The health of the guests, coupled with the name of Sir Patrick Manson, was briefly proposed by Mr. Rutherford. Sir Patrick Manson, in reply, expressed the great pleasure he had at being present and considered that such meetings would be of great benefit to the West African Medical Staff and would be conducive to a feeling of union which would strengthen their hands for good. He was aware that there was a feeling that they had not always received that support in sanitary matters to which they were entitled; this was not due to any want of sympathy on the part of the Colonial Office which was fully alive to the value of their services and was anxious to assist in forwarding sanitary reforms, but was perhaps to be attributed to local conditions. He realised that it was desirable that some form of organisation should be devised which would enable them to bring forward their views in a more direct manner but it was difficult to see how this could be done at once and it was necessary to proceed slowly and cautiously. He hoped that ere long it would be found possible to find some means of surmounting these difficulties. Efficiency in the West African Medical Staff was especially desirable at the present time. They were at the beginning of new developments, of a new pathological era for West Africa, which the political changes of recent years, increasing inter-communication, and, above all, the new railways, were sure to bring about. Diseases formerly limited in their area would become diffused and widespread and diseases hitherto unknown there—for example, plague and cholera—would be introduced.—Mr. G. T. Whyte, medical officer in Northern Nigeria, has resigned his appointment with effect from Oct 4th, 1907. Mr. P. Phillips, medical officer in Southern Nigeria, has been invalided from the service with effect from Nov. 7th, 1907. Dr. W. Fletcher, D.S.O., medical officer in Southern Nigeria, has retired on pension from Nov. 15th, 1907. Mr. J. D. Small, senior medical officer in Southern Nigeria, has retired on pension from Dec. 12th, 1907. Dr. T. C. Caldwell, medical officer in Southern Nigeria, has been invalided from the service with effect from Dec. 24th, 1907. Dr. D. H. R. Waldron, senior medical officer of the Gold Coast, will retire on pension from Feb. 18th, 1908. Dr. C. R. Chichester, senior medical officer in Northern Nigeria, will retire on pension from March 28th, 1908. Dr. J. A. Pickels, medical officer in Southern Nigeria, has been promoted to senior medical officer, vice Mr. J. D. Small. The following gentlemen have been appointed to the staff:—Sierra Leone: Mr. J. C. Murphy, dated Nov. 16th, 1907. Northern Nigeria: Mr. F. E. Bissell, dated Nov. 16th, 1907. Southern Nigeria: Dr. G. Beatty, dated Dec. 28th, 1907; and Mr. W. R. Larbalestier, Mr. W. S. Snell, Dr. T. L. Craig, and Dr. J. Boyd, dated Jan. 11th, 1908.

DR. A. NEWSHOLME AND BRIGHTON.—At a special meeting of the Brighton town council on Jan. 30th it was unanimously decided that the following resolution should be engrossed on vellum, sealed with the common seal of the borough, and presented to Dr. Newsholme:—

> That the council with great regret accept the resignation of Dr. Newsholme, medical officer of health for the borough, and tender him their very hearty congratulations upon his appointment as head of the medical department of the Local Government Board. They desire to assure Dr. Newsholme of their high appreciation of the unstinted service rendered by him to the inhabitants of the borough during the period of 20 years throughout which he has held his important office, by which a continuous and progressive decline in the death-rate has been brought about, the housing conditions of the poor have been greatly improved, and the standard of public health administration has been raised to a very high degree of efficiency. They further wish to congratulate Dr. Newsholme upon his early recognition of the importance from the public health standpoint of the treatment of consumption and upon the national service which he has rendered in the department of medical science.

At the same meeting Dr. Newsholme was allowed to terminate his engagement on Feb. 3rd, thus abrogating the usual quarter's notice, and Dr. Henry Collier Lecky, resident medical officer of health at the sanatorium, was appointed acting medical officer of health pending the appointment of a successor to Dr. Newsholme.

SECOND ANNUAL DINNER FOR PAST AND PRESENT STUDENTS OF THE ROYAL LONDON OPHTHALMIC HOSPITAL.—The second annual dinner for past and present students of the Royal London Ophthalmic Hospital was held at the Trocadéro Restaurant on Jan. 29th, under the presidency of Sir John Tweedy, consulting surgeon to the hospital and late President of the Royal College of Surgeons of England. About 60 past and present students and guests were present and the success which attended the initiation of this celebration last year, under the presidency of Mr. Jonathan Hutchinson, was repeated. Sir John Tweedy proposed the toast of "The Moorfields Hospital and Medical School" in felicitous terms, response being made by Mr. Sturgis, chairman of the hospital committee, and Mr. W. T. Holmes Spicer, dean of the school. The latter drew attention add it to the heterogeneous category of such without violence, for it is as simple in structure, though not in its origin, as a cyst, say, of the urachus. It is a cyst produced from an embryo and I venture to name it an *embryonal cyst*. And such teratoma may become the seats of malignant disease. We may be sure that the localised epithelioma or squamous-celled carcinoma encountered at times in an ovarian cyst has arisen in the cutaneous covering of a teratoma. But more frequently the tumour arising from the teratoma is of a mixed kind; all the histological elements of the teratoma, seeing that they are all embryonic residua, may partake in the abnormal overgrowth and the resulting tumour may be simple, or malignant producing metastasis. Mr. H. T. Hicks and Mr. J. H. Targett have published two cases of malignant embryoma of the ovary, one of the patients being but six years of age. And a case of yet younger age is recounted by Mr. L. S. Dudgeon, where a huge tumour of this kind filled the abdomen of a child under four years of age. In some of the similar cases reported cerebral tissue has been found in the tumour.

To return now to the theories which have at different times been advanced in explanation of the so-called ovarian dermoid. One, which has been long held, is that such cysts result from an impregnation which has been relatively abortive and incomplete in result. As a sufficient refutation of this view it can be pointed out that these cysts may be met with in the unmarried and in children, and this objection has not yet been met. We often find it recorded that a patient from whom such a teratomatous cyst was taken was unmarried. Yet such a history of itself is scientifically inconclusive in this regard. And then we come across one of those decisive but simple observations of Hunter, which forces us to believe that he saw its importance for the simple reason that he made it. In the case of the Hunterian specimen (No. 4508 in the College Museum) we find it recorded that the hymen was intact. The cyst was taken from a woman, aged 18 years, and from its otherwise smooth interior there projects an embryoma covered with piliferous skin and bearing a tooth. And as regards the presence of such cysts in children, No. 4514 is a thin-walled ovarian cyst bearing a small piliferous teratoma, which contains cartilage, the parts being removed from a girl, aged eight years. It is clear, moreover, that in the case of the teratomatous or so-called dermoid cyst of the testicle the theory of a post-natal impregnation is reduced to an absurdity. The view usually adopted in regard to the ovarian teratoma is that the latter is due to the impaction of a second individual which has started on its development synchronously with its host but which has subsequently failed in its progress.

The chief argument against the theory of a twin impaction in explanation of the ovarian embryoma is the sheer commonness of the latter; partly this and partly the difficulty of understanding why such an impaction should so regularly take place into the substance of the ovary and why, being so common in the ovary, it should be of such excessive rarity in the testicle, seeing that these organs occupy the same primitive position and are, in fact, at first indistinguishable from one another. The occurrence, again, of a teratomatous cyst in each ovary adds to the difficulty of accepting this explanation. This bilateralism is, indeed, very far from rare. The presence of two or even three teratomatous cysts in the same ovary accentuates the difficulty, for it would involve the impaction of as many embryoes.

A further difficulty in regard to the theory of impaction arises from the discrepancies referable to the colour of the hair in such cysts. In multiple teratomatous cysts of the same ovary the hair may be of different colour. In bilateral dermoids, too, the hair may be of different colours; it has been found dark in one cyst and light in the other. The colour of the hair in the dermoid again may be markedly different from that of the patient. In the case described in the present communication the hair of the teratoma, which consists of a tuft growing from the pubes, the parasite being acephalous and devoid of teeth, is of the palest flaxen, whilst that of the patient is of a well-pronounced or medium brown, although, as is so regularly the case, it had darkened since infancy; it is fair, however, to contrast the two, for the growth of the pubic hair in the parasite must be regarded as synchronous with the puberty, and not with the infancy, of the patient. A more striking instance of this diff-rence is afforded by a specimen in which the cyst is filled with a mass of shed hair, the colour of which is flaxen or light yellow; hair of similar colour grows from the teratoma: the hair of the patient and that of her husband are of a full black.

Such facts go towards showing, in the first place, that the piliferous skin of the "ovarian dermoid" has not the same histological origin as the skin of the patient, i.e., that its pertaining epidermis is not a portion of the general and primitive epiblast. In the second place, they go towards showing that the embryoma is not an impacted homologous twin. For such twins (which arise from a single ovum, are formed on a single blastodermic vesicle, and inclosed within a single amniotic sac) are not only of the same sex, but so alike in detail as to be with difficulty or not at all distinguishable. This, too, is true of double monsters, which have the same kind of origin as homologous twins, from the misdevelopment of which they arise. For the colour of the hair is, I find, invariably the same upon the two heads. Were the ovarian embryoma due to the impaction of a homologous twin its hair should be of the same colour as that of the patient; and in the case of multiple embryomata it should, moreover, be of the same colour in all.

The foregoing considerations lead me to propose a theory which may explain both the frequency of the ovarian embryomatous cyst and its particular location, a theory, moreover, with which the occurrence of embryomatous cysts in the testicle is not incompatible and which at the same time is in harmony with their rarity. This theory is, that the ovarian teratoma results from the fertilisation of one of the primordial ova in the ovary of the embryo, so that the embryo gives rise to a second imperfect individual whose origin is, therefore, not synchronous with but of later date than itself. It is the formation of one embryo within another, and the name I venture to suggest for the theory is that of epi-embryogenesis.

With respect to the access of spermatozoa to the primitive ova, it is not necessary to suppose that a second penetration of the developing ovum takes place. It is well known that more than a single spermatozoon may perforate the investing membrane of the ovum. It becomes thus quite conceivable that surplus spermatozoa may remain about the segmenting mass or morula, may become engaged between its component cells, and in this way be actually ready in the blastoderm to fertilise the primordial ova which are developed so soon after its lamination and the cleavage of the mesoblast which results in the formation of the body-cavity. The longevity of spermatozoa when under conditions not adverse to their life is a subject upon which little is known. Somewhat to the point, however, is the fact, well known to poultry breeders, that after a single impregnation the hen of the turkey will lay her whole brood—that is, will lay the entire succession of fertile eggs, about 12 in number, which makes the brood, one egg being laid about every other day and the whole process extending over a period of about four weeks. Mr. W. B. Tegetmeier has told me that he knew of one instance in the common fowl in which fertile eggs were laid and hatched six weeks after the access of the male bird.

Not only does this theory of an epifecundation of primordial ova in the ovary of the embryo explain the frequency and particular location of embryomatous cysts of the ovary, but it explains the multiplicity of such cysts in the same ovary and their occurrence in both the ovaries of the same patient. The theory, again, will account for the difference in colour of the hair in multiple teratomatous cysts, or of the teratomata in cysts of opposite ovaries. For such differences become examples only of the differences in colour so frequently seen in children born of the same parents, or still more closely in heterologous twins whose hair may be of different colour. Nor does the difference in colour between the hair of the embryoma and that of the patient offer any difficulty. The patient is, whilst yet an embryo, the mother of the teratoma; the father of the teratoma is the father of the patient. The colour of the hair of the embryoma need not therefore resemble that of the patient, the mother; it might resemble that of the father, or it might not resemble either, but that of a more remote ancestor.

Amongst zoologists three methods of embryogenesis are recognised in addition to the common one in which the ovum, previously and independently matured by the extrusion of its polar globules, is fertilised by a spermatozoon. 1. Shock-fertilisation: this involves the preliminary independent maturation of the ovum, but the incentive to the subsequent division of the latter and the development of the embryo is mechanical. The ova of the star-fish, as is now universally known, can be fertilised by means of "soda-water" added to the sea-water of the aquarium, or by mere shaking. 2. Parthenogenesis, which takes place in many of the insecta (particularly the bee), involves a maturation of th, Royal United Hospital.—House Physician, also House Surgeon. Salaries £80 per annum, with board, lodging, and washing.

rkenhead Borough Hospital.—Senior Resident House Surgeon. Salary £100 and fees. Also Junior Resident House Surgeon. Salary £80 and fees.

righton, County Borough of.—Medical Officer of Health. Salary £800 per annum.

righton, Sussex County Hospital.—House Physician, unmarried. Salary £70 per annum, with board, residence, and laundry.

righton Throat and Ear Hospital, Church-street, Queen's-road. —Non-resident House Surgeon for six months, renewable. Salary at rate of £75 per annum.

ristol Royal Hospital for Sick Children and Women.—House Surgeon. Salary £60 per annum, with board, rooms, and attendance.

ristol Royal Infirmary.—Obstetric Officer. Salary £75 per annum. Also Junior House Surgeon for six months. Salary at rate of £50 per annum. Also Casualty Officer for six months. Salary at rate of £50 per annum. All with board, lodging, and washing.

armarthen, Joint Counties Lunatic Asylum.—Second Assistant Medical Officer. Salary £160, increasing to £180 per annum, with board, lodging, washing, and attendance.

olchester, Essex and Colchester General Hospital.—House Physician. Salary £80 per annum, with board, residence, and washing.

udley, Guest Hospital.—Assistant House Surgeon. Salary £50 per annum, with residence, board, and washing.

rocers' Company's Scholarships.—Two Scholarships for original research in Sanitary Science, value £300 a year each, with allowance to meet the cost of apparatus and other expenses.

ngham Infirmary and South Shields and Westoe Dispensary.—Junior House Surgeon. Salary £90 per annum, with residence, board, and washing.

ing Edward VII. Sanatorium, Midhurst, Sussex.—Junior Assistant Medical Officer, unmarried. Salary £100 per annum, with board, lodging, and attendance.

ing's College Hospital.—Assistant Physician.

icester Infirmary.—Assistant House Physician, for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

indsey County Council, Lincolnshire.—Medical Officer of Health and Medical Inspector of School Children. Salary £400 per annum, rising to £500, with expenses.

ondon Temperance Hospital.—Medical Registrar and Surgical Registrar. Salaries 40 guineas per annum. Also Pathologist and Bacteriologist. Salary 50 guineas per annum. Also Anæsthetist. Salary 20 guineas per annum. Also Radiographer. Salary 10 guineas per annum.

aidstone, Kent County Asylum.—Fourth Assistant Medical Officer, unmarried. Salary £175 per annum, with quarters, attendance, &c.

anchester, Ancoats Hospital.—Resident House Surgeon. Salary £100, with board, residence, &c.

etropolitan Hospital, Kingsland-road, N.E.—Resident Anæsthetist. Salary at rate of £40 per annum.

ullingar District Lunatic Asylum.—Resident Junior Assistant Medical Officer. Salary £100 a year, all found.

ational Hospital for the Paralysed and Epileptic, Albany Memorial, Queen-square, Bloomsbury.—Assistant Pathologist. Salary 50 guineas per annum.

rfolk County Council.—Medical Officer of Health. Salary £500 per annum, rising to £550.

rth-Eastern Hospital for Children, Hackney-road, Bethnal Green, E.—Resident Medical Officer. Salary £100 per annum, with board, residence, and washing.

ttingham City Asylum.—Second Assistant Medical Officer. Salary £150 per annum, with board, apartments, &c.

ttinghamshire Education Committee.—School Medical Officer. Salary £300 per annum, and travelling expenses.

yal Navy, Medical Department.—Examination for not less than 15 Commissions.

Peter's Hospital for Stone, &c., Henrietta-street, Covent Garden, W.C.—Junior House Surgeon for six months. Salary at rate of £50 a year, with board, lodging, and washing.

effield Royal Hospital.—Honorary Assistant Surgeon.

arrington Infirmary and Dispensary.—House Surgeon, unmarried. Salary £80 per annum, with residence and board.

Births, Marriages, and Deaths.

BIRTHS.

derson.—At Newholme, Pitlochry, on the 2nd inst., the wife of John Anderson, M.B., C.M. Edin., of a daughter.

rtis.—On Jan. 31st, at Alton House, Redhill, the wife of Frederick Curtis, F.R.C.S. Eng., &c., of a son.

MARRIAGE.

aylor—Robarts.—On Jan. 30th, at St. John the Baptist Church, Fladbury, Stuart Hopcraft Stanley Taylor, B.A. Cantab., M.B., Ch.B. Edin., of Lacock, Wilts, to Hilda Mary Fanny, third surviving daughter of the late Arthur Frederick Robarts and Fanny Robarts, of Craycombe Pershore, Worcestershire.

DEATHS.

llingham.—On Feb. 4th, at Kingsdene, Worthing, William Allingham, F.R.C.S., aged 72.

arke.—On Feb. 3rd, at St. John's Wood-road, N.W., Benjamin Harris, M.R.C.S. Eng., L.S.A. Lond., aged 70 years.

ttigrew.—On Jan. 30th, at The Swallowgate, St. Andrews, James Bell Pettigrew, M.D., LL.D., F.R.S., F.R.C.P., Chandos Professor of Medicine and Anatomy in the University of St. Andrews.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

MEDICAL CERTIFICATES FOR GOVERNMENT SCHOOL CHILDREN.

A correspondent asks us the oft-repeated question as to how a medical man giving a medical certificate to an educational authority for the absence of a child from school should be paid if the parents are too poor to pay. We have not seen the report of the case in question but we believe the position of affairs to be this. The London County Council has been charged by the Government with the duty of providing education for children and of seeing that they attend school. If the children do not attend school the London County Council has the right to summon the parents of such children and of demanding that they should give a reasonable excuse for their children not having been to school. A medical certificate properly signed by a registered medical man is, we believe, accepted as a reasonable excuse but the London County Council has no legal power to demand a medical certificate. It can only be demanded by the magistrate before whom the parents have to appear. The London County Council, we believe, has no power to pay medical men fees for certifying that the absence of a child is due to illness, and in fact the forms of certificate by the old London School Board had a notice distinctly printed upon them that the school board was not responsible for the fee. As the State requires the County Council to see that the children attend school it would seem to be only fair that the State should also reimburse medical men for certifying that children are unable to attend, but at present this is not the case.

HOSPITAL REFORM.

To the Editor of The Lancet.

Sir,—The few suggestions I venture to make might be the means of drawing out the opinions of other members of the profession as to much needed hospital reform. 1. All hospitals to be under State supervision excepting cottage hospitals in small towns supported by local subscriptions. 2. The staff to be advertised for and selected for their worth, ability, and experience alone, not chosen by interest, canvassing, or by purchase, the usual proceedings. 3. No member of staff to hold *more than one* hospital appointment—a gross injustice to others of equal ability who are thus debarred from obtaining office. 4. The staff to be paid by the State, the fees from students going to help such payment. 5. No out-patients to be treated without letter from one of their local medical men stating they are unable to pay a doctor. 6. Each member of staff to hold office for ten years only and (in any case) to be compulsorily retired at the age of 60 years. These suggestions may lead to far better being proposed, and certainly it appears high time something should be done to alter the plan of assessment of each hospital's claim on the King's Fund so as to improve on the usual one—viz., bulk of patients attended to—naturally making the staff of each hospital anxious for crowded attendance (numbers of whom can afford to pay cost of coming from a distance but prefer to save the money—by paying no doctor's fee—for admission to football-match, music-hall, or perhaps a drunken debauch).

I am, Sir, yours faithfully,

Feb. 4th, 1908. A Former Hospital Physician.

A WARNING.

To the Editor of The Lancet.

Sir,—I am informed that a young man, pretending to be a son of mine, is going about asking for pecuniary assistance. This person is an impostor and I shall be glad to hear that he is in custody.

I am, Sir, yours faithfully,

Upper Brook-street, W., Feb. 4th, 1908. F. H. Champneys.

THE MUFFIN-MAN.

So *far* as the streets of London are concerned which are inhabited by the more well-to-do class of citizen, the itinerant muffin-man's bell is less often heard than formerly, and probably we may regard the sale of muffins and crumpets from a tray carried on the vendor's head as a "disappearing industry." Its survival is not likely to be fostered by a recent prosecution at the Marylebone police court of a muffin-man for ringing his bell, although he was not fined by Mr. Plowden but was allowed to go upon payment of the costs, a sum of 2s. only. The magistrate informed the defendant that he was prosecuted under an Act of Parliament passed 60 or 70 years ago which provides a penalty for the use of any noisy instrument for the purpose o selling anything. It may also be observed that the man in question appears to have been made the subject of legal proceedings by the police not on account of their solicitude for the nerves of the ordinary citizen but because he was rousing some police officers who were asleep after night duty. Protest has frequently been made in The Lancet against the annoyance and even injury to health caused by street noises in a vast city like London where the majority of the inhabitants are workers, and it is a matter for observation that the police should have be an immense step in the direction of stamping out consumption. In any case, the serum is quite harmless and will only be used with the full consent of those parents whose children have been exposed to infection.

METHOD OF TREATMENT.

It is preferable (though not necessary) that the patient should stay in bed a few days before and after the first injection. The temperature and pulse should be noted every four hours before treatment and if not above 100° F. at any time the first injection of 0·0001 milligramme may be given under the skin with, of course, the strictest aseptic precautions. The temperature and pulse should be taken every two hours afterwards for 24 hours and then every four hours for 48 hours more. If any reaction is going to take place the temperature will rise up to 100° or 101° within the first 12 hours or even later; but experience has shown that if the injections are commenced with such a small dose and slowly and gradually increased no reactions follow and beyond an occasional slight headache or feeling of sickness no disagreeable symptoms are observed. In fact, many patients visit the consulting-room for their injections every week and continue their ordinary duties in the interval without any personal inconvenience. The second injection of 0·0002 milligramme is given after an interval of one week, provided no reaction has followed the first injection, in which case the first injection is repeated and then doses (in milligrammes) in the following order: 0·0004, 0·0005, 0·001, 0·002, 0·0025, 0·003, 0·004, 0·005, 0·0075, and 0·01 (maximum dose), making in all 12 injections. If the patient requires further injections the last injection of 0·01 milligramme is repeated for a few more doses but that dose is never exceeded. After the first two or three injections the patients feel better, the temperature drops to normal, the appetite is improved, and there is a feeling of general improvement. Not even the slightest bad effect has been observed from the injections, but of course great care must be exercised in the technique and a careful watch must be kept on the doings of the patient during the course.

Many of us had experience of the tuberculin introduced to the profession by Professor Koch 16 years ago. It was used in a great many cases of phthisis and other forms of tuberculosis without discrimination, but it was soon found that the most marked effects of the tuberculin were produced by injecting it in cases of lupus. I well remember, after obtaining it with great difficulty, injecting several cases of lupus. The reaction was terrific, and from notes of one of my cases I find that the temperature ran up to 105°, the pulse 140, whilst the inflammatory reaction on the lupus itself was most intense. The patient complained of a hot, parched, burning sensation all over his body—in fact, felt he was going to die. In the course of five days he developed acute tuberculous meningitis and died within a week. Although I had no other fatal cases yet in most of them the reaction was acute and in some alarming. In four cases of phthisis in which I used it the patients were made rapidly worse; in fact, the effects were so serious that the remedy was very quickly dropped by the profession. We now know that the only fault of the tuberculin was its dosage. It was a powerful remedy and too large a dose was administered without the slightest scientific knowledge as to its action. At the present time the effects of tuberculin are produced by the administration of minute doses with careful observation as to the effects of each dose. The tuberculin is slowly increased in strength, thus gradually immunising the patient to it until by degrees a maximum dose of $\frac{1}{100}$th part of a milligramme is administered.

In the year 1897 on the introduction of Koch's new tuberculin, or tuberculin R., I made a series of observations on 18 cases of phthisis and recorded the results in THE LANCET at that time. The dosage commenced with $\frac{1}{1000}$th milligramme and was slowly raised to 1 milligramme as a maximum dose. Even that dosage was found to be too high and I think the present method is scientifically correct. The results of that series of cases were not encouraging. In only one case of phthisis could we see any definite improvement. The remaining 17 cases were not in any way improved but they were certainly not in the slightest degree damaged by its use. Since then I have used Koch's tuberculin R. in a large number of cases of phthisis, and I came to the conclusion a year ago, after a very careful examination of its effects, that it was not beneficial in phthisis. But the same cannot be said when we inject Koch's tuberculin into other forms of tuberculosis. In fact, as I have mentioned before, the injection of this tuberculin has a most marked and lasting curative effect, so much so that now it is my routine practice to give every suitable case of surgical tuberculosis injections of Koch's tuberculin and also every case of early phthisis injections of tuberculin prepared from bovine sources. The results are most encouraging and in some cases wonderful, and I am convinced that the treatment of the future of tuberculosis in all its forms will be by the physician rather than by the surgeon.

I now proceed to relate the particular cases in which tuberculin has been used, and although it is impossible to enter into details in this short paper yet I will endeavour as far as possible to classify the different groups of cases with their results.

PHTHISIS PULMONALIS.

At the present time there are 16 cases of phthisis pulmonalis under treatment by injections of bovine tuberculin. They are all adults, nine women and seven men, and in each case the disease is in the first stage according to the classification of Turban—that is, involving one lobe of one lung, or both apices limited to above the clavicle and spine of the scapula. In ten of the cases tubercle bacilli were found; in the other six cases no expectoration could be obtained.

The following is a brief account of the 16 cases:—

CASE 1.—Male, aged 23 years. History of hæmoptysis six months ago; constant cough and slight expectoration. Tubercle bacilli found. He had been steadily losing weight and has even now a typical cachexia. Temperature 100° F. at night. He has had ten injections of tuberculin, commencing with 0·0001 milligramme and rising to 0·01 milligramme. He left the hospital after three months' treatment, having gained 10½ pounds and with total disappearance of all physical signs, cough, and expectoration, and with a normal temperature. He has since been seen on several occasions and remains well and at work. He had only early infection of the left apex.

CASE 2.—Male, aged 31 years. Early phthisis with consolidation of right apex. Tubercle bacilli found in sputum; profuse night sweats and loss of flesh for five months. The usual injections were commenced four months ago with the result that steady improvement has followed. Physical signs have practically disappeared and the man is feeling very much better.

It is, of course, too early yet to give a final verdict, but in this particular case the tuberculin has had a marked effect.

CASE 3.—Female, aged 31 years, with marked physical signs of tuberculosis at both apices. She is of rather frail and delicate constitution but there is no family history of tubercle. She had tried sanatorium treatment for two months but had to give it up on account of it not agreeing with her—in fact, she lost weight whilst in the sanatorium. Injections were started in July last and she has altogether had 14 injections at intervals of one week. Her cough has entirely disappeared, expectoration is almost *nil*, temperature is normal, and she has gained 20 pounds.

CASE 4.—Male, aged 17 years, with active tubercle of the left upper lobe. He was losing weight steadily and had a troublesome and continued cough with expectoration which contained tubercle bacilli. He has had nine injections and is steadily progressing towards recovery.

CASE 5.—Male, aged 23 years, with active phthisis of the right apex, temperature ranging to 101° F. with persistent cough, especially at night. He had hæmoptysis six weeks before treatment. He has had ten injections of tuberculin, has gained 17 pounds, and is steadily improving.

CASE 6.—Female, aged 29 years, with fairly extensive pulmonary tuberculosis and laryngitis. The cough and dyspnœa were very urgent. There was considerable ulceration of the larynx and she had great distress and pain in swallowing, especially hot liquids. Although it was not a case that one would select for treatment yet it was thought that something ought to be done to relieve the distressing laryngeal symptoms. She had altogether seven injections of tuberculin but I regret to say without any good effect whatever, so that they were discontinued. She died two months afterwards and at the necropsy there was considerable destruction of both lungs, with serious involvement of the larynx and extensive secondary ulceration of the intestines, a condition that I invariably find where the larynx is much involved. This case strongly supports the view which I hold—namely, that tuberculin can only be useful in a localised infection of tuberculosis. In other cases it has no immunising effects whatever, and I am rather inclined to believe, although I am not certain, that it may intensify the tuberculous process.

CASE 7.—Female, aged 19 years, with early phthisis at the left apex. She was very thin on admission and had been steadily going down-hill for the last 12 months. Cough troublesome; expectoration profuse in the morning. Under tuberculin she improved rapidly, and in 13 weeks she gained 24 pounds and left the hospital apparently quite well. Tubercle bacilli were never found in her expectoration, although the physical signs of phthisis were quite pronounced.

CASE 8.—Female, aged 26 years, a nurse, contracted phthisis probably from her husband who died from it. She had well-marked signs of tubercle over the whole of the left lobe in front and behind, constant cough and expectoration, progressive loss of weight and profuse night sweats. Tubercle bacilli were found in her expectoration and she readily consented to inoculation. After 13 injections she made a complete recovery. Physical signs were greatly diminished, although there was still some diminished resonance over the affected lung; tubercle bacilli disappeared from her sputum, her cough and night sweats entirely disappeared, and she gained 28 pounds in weight.

This I consider one of the most successful cases of the series.

CASE 9.—Female, aged 26 years, with marked phthisis at the left apex. She had been losing ground for the last 12 months, with cough,

TUESDAY.—Clinique:—10.30 A.M., Medical Out-patient (Dr. A. G. Auld). 2.30 P.M., Surgical Operations (Mr. Carson). Cliniques:—Surgical Out-patient (Mr. Edmunds); Gynæcological (Dr. A. E. Giles).

WEDNESDAY.—Cliniques:—2.30 P.M., Medical Out-patient (Dr. Whipham); Dermatological (Dr. G. N. Meachen); Ophthalmological (Mr. R. P. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations. (Dr. Giles). Cliniques:—Medical Out-patient (Dr. Whiting); Surgical Out-patient (Mr. Carson); X Ray (Dr. Pirie). 3 P.M., Medical In-patient (Dr. G. P. Chappel). 4.30 P.M., Throat Operations (Mr. Carson).

FRIDAY.—10 A.M., Clinique:—Surgical Out-patient (Mr. H. Evans). 2.30 P.M., Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld); Eye (Mr. Brooks). 3 P.M., Medical In-patient (Dr. M. Leslie). 4.30 P.M., Demonstration:—Mr. R. P. Brooks: Selected Eye Cases.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2.15 P.M., Sir Dyce Duckworth: Medicine. 2.30 P.M., Operations. 3.15 P.M., Mr. W. Turner: Surgery. 4 P.M., Dr. StClair Thomson: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

TUESDAY.—2.15 P.M., Dr. R. T. Hewlett: Medicine. 2.30 P.M., Operations. 3.15 P.M., Mr. Carless: Surgery. 4 P.M., Mr. M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

WEDNESDAY.—2.15 P.M., Dr. F. Taylor: Medicine. 2.30 P.M., Operations. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye. 3.30 P.M., Special Lecture:—Mr. Cargill: The Diagnosis of Errors of Refraction.

THURSDAY.—2.15 P.M., Dr. G. Rankin: Medicine. 2.30 P.M., Operations. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Mr. M. Davidson: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 2.15 P.M., Special Lecture:—Dr. Rankin: Neurasthenia, its Etiology and Treatment.

FRIDAY.—2.15 P.M., Dr. R. Bradford: Medicine. 2.30 P.M., Operations. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

SATURDAY.—2.30 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway-road, N.

MONDAY.—9 A.M., Operations (Mr. White). 2.30 P.M., In-patients—Medical (Dr. Beevor); Out-patients—Medical (Dr. Willcox), Surgical (Mr. Low), Eye (Mr. Morton and Mr. Coats).

TUESDAY.—2.30 P.M., In-patients Medical (Dr. Beale), Throat and Ear (Mr. Waggett); Out-patients—Surgical (Mr. Edmunds), Throat and Ear (Mr. French); Operations (Mr. Beale).

WEDNESDAY.—2.30 P.M., In-patients—Surgical (Mr. Stabb); Out-patients—Medical (Dr. Horder), Gynæcological (Dr. Lockyer), Skin (Dr. Whitfield), Teeth (Mr. Baly); Operations (Mr. Stabb).

THURSDAY.—2.30 P.M., In-patients—Medical (Dr. Morison).

FRIDAY.—3.30 P.M., Lecture:—Mr. G. B. M. White: Urethral Stricture.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Lecture:—Sir W. Gowers: Clinical.

FRIDAY.—3.30 P.M., Lecture:—Dr. Batten: Hereditary Ataxy.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, Leicester-square, W.C.

THURSDAY.—6 P.M., Lecture:—Dr. M. Dockrell: Treatment (Constitutional and Local in all its Forms).

CHARING CROSS HOSPITAL.

THURSDAY.—3 P.M., Demonstration:—Dr. Galloway and Dr. MacLeod: Diseases of the Skin. 4 P.M., Demonstration:—Mr. Boyd: Surgical. (Post-Graduate Course).

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.

WEDNESDAY.—4 P.M. Lecture:—Dr. Habershon: Cases from the Wards.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY.—4 P.M., Lecture:—Mr. Corner: Injuries and Diseases of the Epiphyses.

ROYAL INSTITUTION *OF GREAT* BRITAIN, Albemarle-street, Piccadilly, W.

TUESDAY.—3 P.M., Prof. W. Stirling: Membranes—their Structure, Uses, and Products.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1907, which was completed with the issue of Dec. 28th, were given in THE LANCET of Jan. 4th, 1908.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1907 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

During the week marked copies of the following newspapers have been received:—*Edinburgh Evening News, Morning Post, Daily Chronicle, Daily News, Manchester Dispatch, Northern Whig, Bournemouth Echo, Westminster Gazette, Cork Examiner, Lymington Chronicle, Poole Herald, Coventry Times, The Tribune, Daily Graphic, Liverpool Courier, Manchester Courier, Daily Express, Birmingham Post, &c.*

from human sources and exactly in contra-distinction to the cases of phthisis which were treated by a bovine tuberculin. In summing up the treatment of surgical tuberculosis I have found that if there is any waxy disease present the tuberculin has no effect, so that it is important to find out before treatment is commenced, especially in chronic cases, the condition of the liver, spleen, and kidneys. A large number of similar cases will be placed under treatment during the next few months and I hope to be able to record similar satisfactory results.

I would strongly advocate the treatment to be carried out by practitioners on their patients in their own homes. If careful precautions are observed there is no risk or danger whatever, and, from my experience, the tuberculin is carefully prepared and standardised by the Clinical Research Association at a moderate cost.

The following is a summary of the cases treated by Koch's tuberculin: glands in the neck, 23; lupus of the face, 24; joints, 27; peritonitis, 8; meningitis, 4; tuberculous sinuses, 18; total 104. Number of cases treated by tuberculin prepared from bovine sources: phthisis pulmonalis, 18.

ON A CASE OF ACUTE POLIOMYELITIS ASSOCIATED WITH A DIPLOCOCCAL INFECTION OF THE SPINAL SAC.

BY WILLIAM PASTEUR, M.D. LOND., F.R.C.P. LOND.,
PHYSICIAN TO THE MIDDLESEX HOSPITAL;
ALEXANDER G. R. FOULERTON, F.R.C.S. ENG.,
D.P.H. CANTAB.,
LECTURER ON BACTERIOLOGY AND ON PUBLIC HEALTH TO THE MIDDLESEX HOSPITAL;
AND
HENRY MACCORMAC, M.B., CH.B. EDIN.,
DEMONSTRATOR IN THE BACTERIOLOGICAL DEPARTMENT OF THE MIDDLESEX HOSPITAL.

WHILST it has been recognised for many years that an infective origin is probable for certain nervous affections which have a paralysis of acute onset as their chief clinical manifestation, such as acute poliomyelitis, acute disseminated myelitis, and Landry's paralysis, the evidence indicating the mode of causation has been hitherto of a circumstantial rather than a direct nature. In the course of an investigation into the case which we shall now describe we have obtained, however, further evidence of an important kind, inasmuch as having identified a micrococcus in the spinal fluid withdrawn during life from a boy with symptoms of acute poliomyelitis we have succeeded in producing an ascending motor paralysis in the rabbit, after a prolonged period of incubation, by inoculating this fluid into the subdural space. On the death of the experimental animal we have been able to demonstrate in the cerebro-spinal fluid a micrococcus similar to that seen in the fluid from the human case; and further, by similarly inoculating another rabbit with an emulsion of cerebro-spinal substance and fluid from the first experimental animal we have succeeded in reproducing a motor paralysis, again after a somewhat prolonged period of incubation, and again associated with the presence of the micrococcus in the spinal fluid. But whilst we have succeeded thus in obtaining direct evidence of the infective nature of the illness and of its association with a certain micro-organism, our evidence is incomplete bacteriologically, since we failed to obtain the micrococcus in culture on artificial media, and so are unable to give a complete description of it.

THE CLINICAL HISTORY OF THE CASE.

The patient was a slightly built schoolboy, aged 13½ years, and of rather delicate appearance. The history of the onset of his illness was as follows. He was apparently in his usual health on Nov. 11th, 1906. On the evening of the next day he complained of shooting pains in the thighs and across the abdomen at about the level of the anterior superior iliac spines. He was seriously ill during the night and the following day with severe abdominal pain and quiet delirium. On the 13th he was free from delirium and felt better generally, but during the night he suffered again from sharp pains in the legs, which were increased by movement. On the morning of the 14th the patient was unable to leave his bed because of an almost complete loss of power in both legs. By the 16th he had become quite helpless and, although he could use his arms to some extent, was unable to move himself in his bed. About this time his friends noticed that he was unable to cough. He was admitted into the Middlesex Hospital on the 19th. There was nothing in either the family history or the previous personal history of the patient which appeared to have any direct bearing on his present illness. He was one of a family of five children; the other four were in good health. The patient himself was described as having been always rather delicate and nervous; when younger he had suffered from scarlet fever, measles, chicken-pox, and whooping-cough, and when five years old had been treated at the hospital for rickets and bronchitis. He had had "a fit" on two occasions, once at the age of two years and again two years ago; latterly his general health had been fairly good and there was no history of any special indisposition immediately preceding the present illness.

On his admission into hospital the patient lay helpless in his bed. His complexion was somewhat dusky, his voice was feeble, and there were frequent toneless, non explosive efforts at coughing. The respiration-rate was 40 and the pulse-rate was 100 and regular. The temperature on admission was 99° F., but during the first ten days after admission it ranged between 100° and 103° in consequence of a broncho-pneumonia which was probably secondary to collapse of the left lung. The head was drawn somewhat towards the left side and was moved with difficulty because of muscular weakness, the patient being unable to lift it from the pillow. There was no evidence of any paralysis of the facial, lingual, or pharyngeal muscles; the movements of the eyes were not impaired, the pupils were normal in size and as to movement, and the conjunctival reflex was natural. Both lower limbs were in a condition of complete flaccid paralysis except for some flickering muscular contractions which could be seen on attempts to flex or extend the toes of the right foot. And, except the right peroneal muscles, which responded feebly to strong galvanic stimulation, the paralysed muscles did not react to either faradic or galvanic currents. The plantar, patellar, and cremasteric reflexes were not obtainable. Respiration was entirely thoracic in character; there was no movement of the abdominal muscles in respiration, nor was there any visible contraction of them when the patient attempted to cough or to lift his head from the pillow. The diaphragm was apparently paralysed completely. The patient was unable to turn to either side, but could arch his back slightly. The abdominal and epigastric reflexes were not obtainable. The sphincters were not apparently impaired. The thoracic movements were equal on either side but were distinctly deficient. On auscultation of the front of the chest a fair amount of air could be heard entering the lungs, but a complete examination of the chest was not made at the time because of the severe respiratory distress which accompanied the least disturbance of the patient. On subsequent examination, however, it was evident that there had been some considerable collapse of the lungs, and especially on the left side, as a result of paralysis of the diaphragm and intercostals. The range of movement of the arms was as normal, but the muscular power was notably weak. The extensor muscles reacted to strong faradic currents, the flexors reacted normally. Tactile sensibility and sense of temperature were normal everywhere. There were no abnormal sensations nor was there any exaggerated surface tenderness. The organs of special sense were apparently healthy.

During the first ten days when the patient was under observation his condition was one of much danger because of a broncho-pneumonia which was apparently related to the collapse of the lungs which had followed the paralysis of some of the respiratory muscles. But on Nov. 30th the temperature fell suddenly to normal and the patient's general condition improved quickly thereafter. Some recovery of power in the muscles of the arms, the shoulders, and the neck was evident early in December, and by the end of the year the patient had apparently free use of his arms, could turn readily from side to side in bed, and could raise himself to a sitting posture. Some further improvement followed, but when the patient was shown at a meeting of the Clinical Section of the Royal Society of Medicine on Dec. 13th, 1907, he was still completely crippled so far as any use of his lower limbs was concerned.

The evolution and progress of the symptoms in the case were in complete accordance with the recognised clinical features of acute poliomyelitis, and there was little difficulty

Erasmus Wilson Lecture

ON

OVARIAN TERATOMATA.

Delivered before the Royal College of Surgeons of England on Feb. 10th, 1908,

BY SAMUEL GEORGE SHATTOCK, F.R.C.S.,
PATHOLOGICAL CURATOR OF THE COLLEGE MUSEUM.

[MR. SHATTOCK commenced by describing an embryoma projecting into an ovarian cyst in which the indications of a second fœtus were unusually evident. The embryoma consisted of a trunk furnished with two lower limbs and a peritoneal cavity containing a blind coil of intestine. The skeleton comprised a short rudimentary spinal column with a pelvic girdle, and in each of the lower limbs there was a long osseous element filled with fatty marrow. Between the limbs were two distinct labia bounding a blind depression, and behind these a perineal raphé. The embryoma, except on the soles of the feet, was covered with short fine hair, but over the pubes there was a well-pronounced tuft of long pubic hair. The wall of the cyst into which the embryoma projected was smooth and devoid of hair or epidermal lining. He continued :—]

The growth of pubic hair is a subject of no little interest in this remarkable specimen. It must be taken as marking the advent of puberty. As the presence of sexual glands in the embryoma itself may be excluded (for there is nothing but a coil of intestine in the peritoneal cavity), the explanation of its puberty must be sought in a maternal influence, or more definitely in the action of an internal secretion produced by the sexual glands of the autosite; the autosite and the embryoma will have acquired the cutaneous marks of puberty simultaneously. It is, in fact, a natural experiment which successfully carries out one devised and attempted by Dr. C. G. Seligmann and myself. Our experiment consisted in grafting together by the legs a castrated cockerel (after its recovery) and an intact cockerel of the same age and kind. Although the operation was itself successful, one of the grafted birds, in each of the four cases in which it was carried out, died within a few days without obvious cause. The object of the experiment was to see whether the castrated bird would, as it matured, put on the plumage and comb of the cock from the access of blood to it from the intact bird. In the ovarian embryoma the experiment has been accomplished. The trunk of the embryoma being without heart and independent circulation has been supplied with blood from the side of the autosite and with the result that the overgrowth of hair which marks the advent of puberty has actually been brought about.

[Mr. Shattock next demonstrated a series of ovarian teratomata, showing the progressive disappearance of limbs from an amorphous trunk, the true nature of which latter appeared from the presence of a rudimentary intestine, or (as he had demonstrated in three cases) from the presence of a central nervous system. He continued :—]

The presence of teeth necessarily shows the teratomatous character of the cyst in which they occur; but in the case of other ovarian teratomata, even those of a well-pronounced kind, teeth are wanting. These differences we must attribute to differences in the developmental arrest which involves now one part and *now* another of the embryoma. There are acormous (or trunkless) and acephalous (or headless) embryomata, as there are trunkless and headless acardiac homologous twins. In regard to the displacement or lateral dislocation of dentigerous and other bone, and the utter absence in most cases of any structure morphologically like a cranium, one must not overlook the mechanical action of the enlarging cyst and the pressure of its contents in exaggerating what are, probably, also original defects of formation. The striking length of the hair in certain ovarian cysts, again, can hardly be explained, except by regarding such hair as growing from a cutaneous area answering to the scalp, and this view is strengthened when the hair arises in the neighbourhood of a dentigerous process of bone. The hair in one College specimen (Mr. J. Bland-Sutton's) is 20 inches in length. Here, as in other cases, the mass of hair is confined to an elevation covered with true skin—i.e., to the proper teratoma. But the view that such dentigerous bones represent the cephalic end of an embryo is definitely proved by the presence of central nervous tissue in connexion with them. So long ago as 1853 Henry Gray described an ovarian cyst containing a tooth and hair, and projecting into this cyst was an eminence about the size of a walnut, situated near the dentigerous bone referred to; the wall of this eminence was delicate, its inner surface was highly vascular, and the contents consisted of a soft white substance, the surface of which was perfectly smooth and presented all the characters of brain. On microscopical examination it was found to consist entirely of the ordinary elements of nervous matter, being composed of a very large number of varicose nerve tubules of varying size intermixed with the "elementary components of grey matter—viz, nuclei and nucleated vesicles containing granules."

[Mr. Shattock also demonstrated the presence of a stomodæum with two lips and an appendage containing elastic cartilage and representing a rudimentary pinna at the same end of an elongated ovarian teratoma. He continued :—]

The astonishing excess of teeth, in rare cases met with in a teratomatous cyst, is perhaps explained by the occurrence of twin or triple teratomata in a *single* cyst. Or, it may be that the excess is brought about by an abnormal extension of the epithelial surface corresponding with that of the gum during the early enlargement of the cyst, so that the dental germs are increased in number and give rise to as many teeth or ill-deformed denticles. For even if we allow that two complete sets of teeth, a first and second, have been produced, the total (20 + 32) would not equal the numbers which have been encountered, which may be over 100. One must not, of course, fall into the error of reckoning multiple dentigerous cysts in the same ovary as a single "dermoid," and must also recognise the possibility of such coming to communicate through their partitions so as to produce a single multilocular cavity.

Not one of the least strange things in connexion with ovarian teratomata is that though themselves so abnormal they may nevertheless be the seats of disease. Setting aside the different degrees of aplasia and hypoplasia which, *ipso facto*, they illustrate, or the misdevelopment of particular teeth, or the presence of odontomata upon their fangs, we must look upon the relative amount of fat as in some cases quite reaching the proportion of disease. It is not simply subcutaneous fat duly proportionate to the skin over it, but it may constitute the bulk of the embryoma, the amount of bone and other structures being relatively insignificant as in the case described in the present communication, or in others already referred to from the College Museum (Nos. 4511, 4511A, 4526E). The morbid condition, in short, is that of lipomatosis, or a generalised abnormal formation of fat, as distinguished from a local tumour or lipoma. For it must be borne in mind that the presence of any fat in the ovary itself is something altogether as abnormal as it is in the testicle and that the fat of the embryoma appertains entirely to the latter. I am not aware of a fatty tumour ever having been observed in the ovary. In the testicle I have examined one only, and this in the horse; and so far as my knowledge goes it is unique.

But that hydromyelus should occur is still more strange. Yet it is shown in three of the teratomata already described, from Specimen No. 2371 in St. Thomas's Hospital Museum. In one of these the tubular hydromyelic sac is lined with columnar epithelium and the halves of the spinal cord lie one on either side of it, the whole being invested with a separable membrano-cutaneous covering or body-wall. As there is no spinal column we cannot speak, of course, of a spina bifida. The largest example of this morbid condition of the embryoma is contained within an ovarian cyst in the opposite ovary of the same patient. It consists of a double sac, the portions of which, each about three and a half inches in length, lie side by side, and communicate by a small aperture half surrounded by a process of bone. From the inner aspect of the sac a delicate continuous membrane can be raised; there is no trace of further structure. Yet that this bilocular sac is an embryoma dilated into a great cyst by hydromyelic and hydrocephalic distension is clear if it be compared with that first referred to in which the halves of a spinal cord lie on the sides of the sac; and by the circumstance that the sac itself is furnished with a delicate, separable lining representing the meninges of the dilated central nervous system, and an outer membranous body-wall.

We may, indeed, classify the last as a new form of cyst and examined, but neither any change in the ganglion cells when stained by Nissl's method nor any perivascular change could be detected.

The diplococci, alike in the patient's cerebro-spinal fluid and in that from the rabbits, stained well and deeply with Loeffler's blue, but we were not able to detect any specimens of the micro-organisms in films of the fluid which had been stained by Gram's method, with a counterstain, and so we are unable to state the reaction of the diplococci in this respect. In the rabbits' spinal fluid the diplococci were very sparsely scattered, they were grouped in pairs, occasionally in tetrads, and in one instance (see Figure) a chain of four cocci was noticed.

The results of our inoculation experiments may be conveniently recapitulated in tabular form.

TABLE OF ANIMAL EXPERIMENTS.

Specimens of spinal fluid.	*Series I.*—Animals inoculated with cerebro-spinal fluid from patient.	*Series II.*—Animals inoculated with an emulsion of the cerebro-spinal substance and fluid from rabbits of Series I.	*Series III.*—Animals inoculated with an emulsion of cerebro-spinal substance and fluid from rabbit of Series II.
Specimen I., drawn off on Nov. 22nd, 1906. *Contained diplococci.*	Rabbit 1.—Intracranial inoculation; died on twenty-second day afterwards. *Diplococci present in cerebro-spinal fluid.*	Rabbit 2.—Inoculated on Dec. 14th from Rabbit 1; died on Dec. 25th; cause of death not ascertainable; result of experiment negative. Rabbit 3.—Inoculated on Dec. 14th from Rabbit 1; killed on twenty-sixth day, apparently healthy.	—
Specimen II., drawn off on Dec. 14th, 1906. *Contained diplococci.*	Rabbit 4.—Intracranial inoculation; died from accident within 24 hours of operation. Rabbit 5.—Intracranial inoculation; marked paralysis of hind limbs on fiftieth day after inoculation; partial paralysis of forelimbs on fifty-second day; death on fifty-third day. *Diplococci present in spinal fluid.*	Rabbit 6.—Inoculated on Feb. 6th, 1907, from Rabbit 5; killed under chloroform on forty-first day. Result of experiment negative. Rabbit 7.—Inoculated on Feb. 6th, 1907, from Rabbit 5; complete paralysis of hind limbs and partial of forelimbs on forty-ninth day; killed on fiftieth day. *Diplococci present in cerebro-spinal fluid.*	Rabbit 10.—Inoculated on March 27th from Rabbit 7; died on fourth day after inoculation cause of death not ascertainable. Rabbit 11.—Inoculated on March 27th from Rabbit 7; alive and well four months afterwards.
Specimen III., drawn off on March 25th, 1907. No diplococci seen in cover-glass preparations.	Rabbit 8.—Intracranial inoculation; killed on twenty-first day; result of experiment negative. Rabbit 9.—Intracranial inoculation; alive and well four months afterwards.	—	—
Specimen IV., drawn off on April 17th, 1907. No diplococci seen in cover-glass preparations.	Rabbit 12.—Intracranial inoculation; died on July 2nd from coccidiosis. Rabbit 13.—Intracranial inoculation; alive and well three months afterwards. Rabbit 14.—Intraperitoneal inoculation; died on May 9th from coccidiosis. Rabbit 15.—Subcutaneous inoculation; died on July 12th from coccidiosis.	—	—

AS TO THE INFECTIVE ORIGIN OF SOME CASES OF ACUTE POLIOMYELITIS.

Whilst there is, as we said at the commencement, a considerable volume of indirect or circumstantial evidence which indicates a probable infective origin for, at any rate, some cases of acute poliomyelitis, the only reliable direct evidence as to causation which has been obtained hitherto is that derived from the work of Geirsvold,[2] to which we will refer a little later. The indirect evidence as to the causation of this affection is comprised in records of outbreaks of illness, either limited to a single family or of widely epidemic character, in which an acute paralysis, apparently due to acute poliomyelitis, has been either a prominent primary feature or a frequent consequence.

As a typical example of what may be termed the family outbreak we may refer to the instance recorded by one of us (W. P.)[3] in which an entire family of seven children were attacked by a mild febrile disorder which was followed in between five and seven days by marked motor paralysis in three cases, by muscular tremors and temporary strabismus in another case, and by general muscular tremors in a fifth case. Other outbreaks of similar character have been recorded and most of them are referred to in Dr. Farquhar Buzzard's Goulstonian lectures for 1907 on Certain Acute Infective or Toxic Conditions of the Nervous System.[4]

Epidemic outbreaks of an illness of which acute poliomyelitis was a prominent feature occurred in Norway during the years 1903, 1904, 1905, and 1906, and have been recorded by Geirsvold[5] and by Harbitz and Scheile.[6] Geirsvold, writing in 1905, states that 437 cases of the disease, with 69 deaths, had occurred in Norway during the year. The disease was of an epidemic character, spreading from farm to farm over the whole country. Frequently preceding, sometimes coincidently with, a local outbreak of cases of acute poliomyelitis there were cases of illness of a milder or abortive character. In these milder cases, in which obvious illness lasted for from one to four days, the principal symptoms were those of fever, with rigors, sore throat, sweating, and sometimes evidence of some meningeal irritation. In this type of case paralyses did not occur as a rule but Geirsvold notes that in some of them a progressive paralysis, sometimes terminating fatally, developed after apparent convalescence and after the patient had returned to work, and comments on the likelihood of the mild antecedent illness being overlooked in such cases of late paralysis. In the course of the epidemic children and adults were attacked and whilst some types of the disease resembled in their broad features cases of epidemic cerebro-spinal meningitis caused by diplococcus intracellularis of Weichselbaum a consideration of the epidemic as a whole leaves no doubt as to the different specific nature of the infection.

Dealing next with the direct evidence as to the infective nature of these cases of acute poliomyelitis, one has only to refer to a recent review by Carl Looft[7] of the Bacteriology of Acute Anterior Poliomyelitis to show how contradictory and generally unsatisfactory most of the evidence which has hitherto been brought forward has been. Thus, Harbitz and Bulow-Hansen[8] have recorded the finding of a diplococcus in the spinal fluid of a case of anterior poliomyelitis examined after death. Schultze[9] recorded the finding of the meningococcus in a single case, and in a second communication[10] recorded the finding of diplococci in two other cases, one of which, however, appears to have been of a tuberculous nature. Concetti[11] has published the results of the ovum, but not a proper fertilisation, the embryogenesis being started by the return, or want of extrusion, of the second polar globule which acts in place of the male element. 3. Sporogeny: here the embryo develops from the ovum without any preliminary maturation of the latter and apart from fertilisation. This phenomenon has been observed in the jelly-fish.

The theory of epi-embryogenesis in connexion with ovarian embryomata involves (as would also that of parthenogenesis) a premature preliminary "maturation" of the ovum, seeing that the process of fertilisation would take place in the embryo itself. The phenomenon of parthenogenesis, however, is limited to forms so far below mammals that it is difficult to think it obtains with such great frequency in the human subject as the common occurrence of ovarian teratomata would necessitate. Still more inapplicable is the phenomenon of sporogeny, the only one which does not involve a histological maturation of the ovum, when the extreme lowness of the forms in which it occurs is considered.

Let me, in conclusion, take up the difficulty presented by the occurrence of similar embryomatous cysts in the testicle. How is the extremely rare occurrence of such cysts to be accounted for on the theory advanced? In the embryonic sexual gland the proper reproductive cells are at first undifferentiated from one another. These cells become in the female the ova and in the male the spermatogenic elements of the testicle. The occurrence of embryomatous cysts of the testicle, then, would involve on the theory of epi-embryogenesis a hermaphrodite condition of the gland in which the cyst is formed, and the intra-embryonic fertilisation of one of the ova. True it is that in the human subject the condition of glandular hermaphroditism is but rarely observed, but still more rare is the teratomatous cyst of the testicle. The rarity of the one accords with the rarity of the other. Yet on any of the other theories advanced such cysts should be as frequent in the testicle as they are in the ovary.

A Lecture

ON

THE TREATMENT OF TUBERCULOSIS BY DIFFERENT KINDS OF TUBERCULIN.

Delivered at the Medical Graduates' College and Polyclinic, London, on Nov. 12th, 1907,

BY NATHAN RAW, M.D., M.R.C.P. LOND.,
F.R.S. EDIN.,

PHYSICIAN TO THE MILL ROAD INFIRMARY, LIVERPOOL; MEMBER OF THE INTERNATIONAL COMMITTEE FOR THE PREVENTION OF CONSUMPTION, ETC.

GENTLEMEN,—The treatment of phthisis pulmonalis and other forms of tuberculosis is of such intense urgency and importance that any method based on scientific investigation ought to be thoroughly tested with a view to diminish the awful mortality in this country from tuberculosis. I have been greatly disappointed in the treatment of phthisis by Koch's tuberculin R., but in the treatment of surgical tuberculosis, such as tuberculous peritonitis, meningitis, bone and joint disease, enlarged glands and lupus, the results with tuberculin R. (Koch) have been most excellent, and I have at present a great many cases under treatment in hospital by this tuberculin as supplied by the Clinical Research Association.

I have recently had prepared from my own cultures of bovine tubercle a tuberculin for use in phthisis pulmonalis with, so far, encouraging results. A perusal of my paper in the April, 1907, number of *Tuberculosis* (Berlin) will explain the reason why tuberculin from bovine sources should be used for phthisis, whilst Koch's tuberculin R., which is prepared from human tubercle bacilli, should be used for the other forms of tuberculosis. The general results and impressions of that work are given here, but in the limited space at my disposal it is impossible to do more than touch generally on a few of the more important points investigated during this research.

Following the lines of my original paper of 1903, I have no reason to modify the view then set forth—namely: "That human and bovine bacilli are divisible into two distinct types of a common species: (1) typus humanus; and (2) typus bovinus." Another fact of the most profound importance in studying this problem is that for centuries man has been accustomed to feed upon cattle and their products—milk, butter, cheese, &c.—and in this way the human body has become tolerant to bovine tubercle bacilli. Whilst I firmly believe that human and bovine bacilli are different types of parasites, yet I am convinced that bovine bacilli are freely communicable to humans and are the cause of a large amount of tuberculosis in children. I believe that man is attacked by two distinct varieties of tubercle, one conveyed by infection from one person to another, the other by receiving into the body bovine bacilli from infected food. In other words, the human body is susceptible to both forms of tubercle. The difficult problem to determine now is what particular lesions in the human body are produced by each variety of tubercle.

To sum up my own views on the distribution of tubercle in the human body, I would say, speaking provisionally and without any final evidence of proof, that (1) tubercle bacilli of the typus humanus produce phthisis pulmonalis, ulceration of the intestines, and tuberculous laryngitis; and (2) tubercle bacilli of the typus bovinus produce tuberculous peritonitis, tuberculosis of the lymphatic glands, tuberculous joints, meningitis (probably), and lupus. I am of opinion, also, that acute miliary tuberculosis is of bovine origin.

Working on the hypothesis that the human body is attacked by two varieties of tubercle which may be present in the body at the same time and which, generally speaking, are antagonistic to each other, I have devoted my attention within the last few months to the preparation of tuberculins for the treatment of these different lesions. After a fairly complete experience I have come to the conclusion that Koch's tuberculin R. has little or no healing effect in phthisis pulmonalis, and when we remember that it is manufactured from human tubercle, if my theory is correct it is exactly what we would expect. Consequently I have had prepared from one of my own pure cultures from bovine sources a special tuberculin for the treatment of phthisis pulmonalis. The tuberculin was made from a typical culture of "perlsucht" and was very carefully sterilised and standardised. Several guinea-pigs were inoculated but without any bad effect. Working on these lines I am at present treating over 70 cases of surgical or bovine tuberculosis in the wards of Mill Road infirmary with Koch's tuberculin R., commencing with very small doses and slowly increasing up to a maximum dose of one-hundredth of a milligramme. The results, without any accessory treatment, have been beyond all my anticipation. Enlarged glands, joints, and lupus have been immensely improved, whilst discharging sinuses have cleared up and in two cases the symptoms of tuberculous meningitis associated with tuberculous peritonitis entirely disappeared. The full results of this large number of cases treated by tuberculin will be published in due course. On the other hand, I have treated 16 cases of early phthisis, four of which were associated with hæmoptysis and all of which showed tubercle bacilli in the sputum, with distinctive physical signs at one apex, with the tuberculin prepared from a pure culture of bovine tubercle (kindly supplied to me by Professor Calmette of Lille). These cases are still under treatment, but up to the present many of them have shown marked improvement, with total disappearance of physical signs. It is too soon yet to speak of the final results of treatment, but I hope to publish them after one year. My tuberculin should only be used in early cases and, if possible, in conjunction with open-air or sanatorium treatment. The directions and dosage issued by the Clinical Research Association should be strictly adhered to if good results are to be obtained.

With a view to produce immunity against human tubercle in children, especially in those who have been exposed to infection from a consumptive father or mother, I have lately been working with the serum of tuberculous cattle. I have purchased several dairy cows suffering from tuberculosis of the udder and have obtained, with the kind coöperation of Professor H. E. Annett, a large amount of the serum of these cows. This serum has been very carefully sterilised and injected into guinea-pigs without any ill-effects. I believe that the serum of a cow which has suffered from bovine tuberculosis will confer such immunity when injected into a child as will suffice to protect him against an attack of human tuberculosis. Considering the large number of children who are attacked by phthisis pulmonalis as the direct result of contact with a consumptive parent a protective serum would serums in doses strictly limited in quantity to avoid "inverted action" such as obtains in the analogous case of calcium salts. I found, however, that the clinical results of giving serum in this way in severe cases of hæmorrhage were, apart from hæmophilia, most disappointing. Hæmorrhage was little affected and coagulation time was not accelerated. I therefore gave much larger doses by the mouth and gave it repeatedly, and found it possible to control severe hæmorrhage in cases of purpura, acute hæmatemesis, and in cases of tuberculous hæmoptysis otherwise uncontrollable. Further, by extending the range of application I found that a most remarkable improvement in the clinical symptoms and in the condition of the blood followed in cases of many affections in no sense hæmorrhagic, such as chlorosis and ulcer without hæmorrhage. Hence, whatever value normal serum therapy may prove to have, it does not seem obviously connected with supplying fibrin ferment.

What the true explanation is must at present be a matter of speculation. It is conceivable that the administration of normal serum may affect the production of auto-anticomplement, or in some unknown way correct a disturbance of the regulating mechanism that Ritchie and others have postulated in order to explain Ehrlich's "horror autolyticus." For instance, in the paper referred to I have suggested that gastric ulcer is not a disease *sui generis* but is merely the local expression of a general blood dyscrasia at present unrecognised and that the essence of such disease may be the presence in the blood of cytolysins for gastric epithelium. The success that I have so far been able to obtain by the repeated oral administration of serum in many of these cases supports the view that it in some way affects the autolysis here supposed to cause the disease. Whatever the explanation, the exhibition of a large number of cases of different diseases treated in this way cannot fail to be of value in determining the utility of the treatment.

It will be seen that many interesting questions will arise in connexion with normal serum-therapy. For instance, what share have the normal constituents of serum in the results obtained by the use of serums such as the anti-diphtheritic and the polyvalents which we now attribute entirely to the action of abnormally produced bodies? Although I am optimistic as to the effects of normal serum-therapy in various conditions, our knowledge of its action is so slight that caution must be exercised in its use, and it is desirable that methods of testing and standardising the serum with regard to its anti-autolytic, anti-hæmorrhagic, and other properties should be employed in the future. It is also important that serum should be used from a horse that has been repeatedly bled, as its activity seems to be thereby enhanced.

The results in some of my own cases have been so striking that an anonymous donor has placed at my disposal a fund for the further investigation of the action of fresh serums. I am by this means able to avail myself of the aid of two other investigators on the staff of St. George's Hospital—viz., Dr. F. L. Golla and Dr. A. J. Jex-Blake, and collateral researches are now being actively pursued in the laboratory and in the clinical wards of several public institutions. I hope shortly, therefore, to present a large series of cases of various diseases treated in this way and to indicate thereby the limit of application. Appended are notes of four cases to indicate the possibilities apparently involved.

CASE 1. *Marked anæmia.*—The patient, an unmarried woman, aged 30 years, looked very ill and anæmic. She had had poor health for three years and had twice been treated in a nursing home without benefit. She complained of obstinate dyspepsia and distaste for food, troublesome constipation and amenorrhœa, slight gastrectasis and heavily loaded tongue, and dyspnœa on the slightest exertion. There was œdema in both legs up to the hips which pitted deeply on pressure. A loud hæmic bruit could be heard and the apex beat was in the nipple line. The urine was normal and there was no enlargement of the spleen. The blood count showed 60 per cent. of hæmoglobin and a fall in red corpuscles to 2,800,000. The blood had never previously been examined. The treatment adopted was rest, simple salines, ordinary diet and serum given in milk by the mouth on the following days—Nov. 24th, 26th, 28th, and 30th, and Dec 1st, 3rd, 5th, 7th, 9th, and 11th. In three days the œdema had nearly disappeared and in a week it was entirely gone, as also were the dyspnœa and dyspepsia. The patient was driving in ten days and walking in 14 days. The blood counts were as follows:—Nov. 20th, hæmoglobin 60 per cent. and red corpuscles 2,800,000; Nov. 26th, hæmoglobin 65 per cent. and red corpuscles 3,500,000; Dec. 6th, hæmoglobin 75 per cent. and red corpuscles 4,000,000; and Dec. 19th, hæmoglobin, 85 per cent. and red corpuscles 4,560,000.

This case, then, was one in which there had been obstinate dyspepsia for three years, which had proved refractory to treatment, and which had been associated with progressive anæmia and latterly marked œdema. Coincidently with the giving of serum there was immediate improvement in all the symptoms and the patient made a rapid recovery.

CASE 2. *Tuberculous hæmoptysis.*—This was an exceptionally good test case. The patient was a man, aged 26 years, with early but rapid tuberculosis of both lungs. When I first saw him in consultation he was bleeding profusely. "Stereotyped" treatment, including calcium chloride, had been tried for three days without avail. Amyl nitrite was the first suggestion that I made. This was as unsuccessful as I have always found it to be. Serum was then given by the mouth and bowel and two doses were sufficient to arrest bleeding. There was no more bleeding of any importance for some weeks when a fresh, though much less alarming, attack occurred. On auscultation a fresh focus of infection was clearly made out. The hæmorrhage was again immediately arrested by giving serum. In the next few months, at intervals of a few weeks, fresh hæmorrhages occurred from fresh foci of infection and in each case were immediately arrested as before by serum. It is fair to add that in two of these attacks the medical man in charge had previously employed again the ordinary methods of treatment without avail. An interesting point in this case was the fact that in spite of the rapid invasion of the lungs at the beginning of treatment by serum the tendency to great improvement, apart from arrest of hæmorrhage, was in the later months manifest. This may or may not have been due to the influence of the serum given, the total amount of which was considerable.

CASE 3. *Probable gastric ulcer without obvious hæmorrhage in a chlorotic.*—The patient, a young woman, aged 20 years, had for seven years suffered from almost constant gastric pain which always became aggravated by taking food and was always referred to one spot, which was also extremely tender. There had been occasional attacks of vomiting but no hæmatemesis and no melæna. Occult hæmorrhage was never searched for. The patient had often for many months at a time been dieted and put on iron with some improvement, but she had often relapsed. There had been no amenorrhœa and the urine was normal. Constipation had been a constant trouble and headache had persisted. No ocular defects had been discovered. The present attack of acute gastric pain with frequent vomiting had lasted for three days. There was extreme tenderness to the left of the epigastrium. A loud hæmic bruit audible over the left chest was loudest in the pulmonary area. There was slight dyspnœa on movement with slight dilatation of the stomach and some stasis of the gastric contents. The patient looked anæmic. The pulse was 110 and the temperature was subnormal. The following treatment was adopted. Complete rest in bed was enjoined and the administration of one drachm of compound liquorice powder every night. Every four hours small meals, in rotation, of stale bread and butter, chicken jelly, and four ounces of milk to which eight grains of sodium citrate were added were taken, and once a day for two days 10 cubic centimetres of normal horse serum were given by the mouth in milk. No other treatment whatever was undertaken. In 48 hours all pain, tenderness, vomiting, and even nausea had entirely disappeared and have not returned. On the third day of treatment pounded fish and chicken and the yelks of lightly-cooked eggs were given. On the fifth day 10 cubic centimetres of serum were given and pounded meat was added to the dietary. On the tenth day the patient was allowed to get up and was given ordinary household diet. On the thirteenth day she was in full work and she declared herself to be in perfect health. On Oct. 21st the hæmoglobin was 65 per cent. and the red corpuscles numbered 5,300,000. On the 27th, after the administration of 30 cubic centimetres of serum, the hæmoglobin was 75 per cent. and the red corpuscles numbered 5,500,000.

This, then, was a case in which there had been a condition of gastric pain for seven years and in which the subacute and acute attacks responded little, if at all, to ordinary treatment. When serum was given an immediate improvement set in and was followed by complete recovery.

CASE 4. *Duodenal ulcer with hæmorrhage.*—In this case, seen by me in consultation, the medical man in charge kindly allowed me every facility and to his courtesy I am indebted for the notes of the case. The patient was an anæmic-looking woman, aged 32 years. For many years she had had constant dyspepsia and severe pain referred always to one spot in the epigastrium, which she found also frequently very tender. The pain had the following characteristics: it sometimes occurred during the swallowing of food and was frequently accompanied by a sense of soreness in the neighbourhood of the cardiac orifice; it disappeared after meals to reappear very constantly after one and a half hours; and it was at times very severe before meals. Constipation had never been troublesome and menstruation had always been normal. Until 12 months ago no evidence had been available as to the presence or the absence of occult hæmorrhage and the patient had never vomited blood or had melæna, but within the last three months both had occurred three times. On the last occasion she went about for three days with duodeno-stasis, still continuing until faintness and impending collapse compelled her to lie up. On examination slight gastrectasis and stasis were present and epigastric pain and tenderness, strictly localised, were elicited. The following treatment was adopted: rest in bed; small frequent meals of pounded chicken fish, brain, eggs, and stale bread, with strictly limited intake of milk, and serum in doses of 10 cubic centimetres given in milk on the fourth, sixth, eighth, tenth, twelfth, fourteenth, sixteenth, seventeenth, eighteenth, nineteenth, and twenty-first days. A control was, so to speak kept in this way. For ten days the patient was given no serum, though complete rest and the above diet were given. No improvement took place until the serum was given. From the first day of its exhibition improvement was marked and progressive. The pain and the vomiting rapidly disappeared, there was no trace of recurrence of hæmorrhage, and the dyspepsia of years had gone. On Oct. 30th the hæmoglobin content was 60 per cent. Serum was first given on Nov. 4th. On the 11th the hæmoglobin was 75 per cent. and on the 26th it was 92 per cent.

The blood counts have been taken for me in the above cases by Mr. E. Quant, F.C.S., of the South Devon Laboratory.

It may at first sight seem unreasonable to expect good results from the application of normal serum-therapy to such expectoration, and night sweats. She made application for admission to a sanatorium but was declined on the ground that her case was not sufficiently early. She has up to the present time had six injections of tuberculin. Her cough has practically gone, physical signs much less active, and she has gained nearly a stone in weight.

The case is still under treatment and I feel no doubt that she will eventually make a complete recovery.

CASE 10.—Man, aged 40 years, in Stage 1 of the disease. Tubercle bacilli found. Has had 11 injections and is steadily gaining weight.

CASE 11.—Male, aged 60 years. Phthisis involving both apices, physical signs most marked behind. He has a very distressing cough; has had two attacks of hæmoptysis. Under tuberculin he has made a little improvement but he does not seem to possess much natural resisting power so that it is rather difficult to produce immunity.

Although the patient is a little better I am not satisfied that he is making any great headway and I rather think of discontinuing the treatment.

CASE 12.—Male, aged 31 years, with active tubercle at the right apex. Had a severe hæmoptysis two months ago when he lost a large quantity of blood. Tubercle bacilli are present and it looked as if he was going to develop acute tuberculosis of both lungs. Things, however, settled down after two weeks' rest and tuberculin was commenced. From the very first injection he commenced to improve, his appetite returned, the cough became less, expectoration not tinged with blood and diminished, night sweats disappeared, and he gained over 18 pounds in weight. At the end of 12 injections he was transferred to our sanatorium where his recovery was completed and he left that institution two months ago with his disease completely arrested.

I examined this patient a few days ago and found him continuing his work with no symptoms at all to cause him any inconvenience. He has still retained all his weight and there are no tubercle bacilli found in the sputum.

CASE 13.—Male, aged 37 years, with tuberculosis of both apices with old pleurisy at the right base. He had been losing weight for two years and has not been able to follow his employment for that time. He came into hospital for the purpose of having injections and has progressed extremely well after ten injections of tuberculin. He has greatly improved, has gained weight, and cough has disappeared.

The case is still under treatment and although I do not hope for cure yet there is certainly great improvement.

CASE 14.—Male, aged 35 years. Tuberculosis at right apex, erratic temperature, quick pulse, night sweats, and emaciation. He was treated for one month on ordinary hygienic principles, with complete rest in the open air—such as we have in Mill Road Infirmary—which had a good effect. Injections were commenced four months ago and although he has only had 10 yet he appears to be greatly benefited and expresses himself as being quite a different man.

I think in this case the disease will be arrested.

CASE 15.—Female, aged 21 years, two sisters having died from phthisis within the last three months. She had only complained for six weeks of cough and expectoration. Temperature was high at night; pulse 120, with progressive emaciation. Under treatment she has made wonderful recovery, although no marked improvement was observed until after the seventh injection. She has now had 13 injections. Her temperature is normal at all times; pulse 90. She has gained 15 pounds in weight and says she is better than she ever was in her life.

The physical signs in this case were limited to the left apex but were evidently of an acute and progressing character. The girl herself had practically no resisting power, consequently she would have very soon been destroyed by the tubercle bacilli. This is an example of the excellent effects of tuberculin.

CASE 16.—Female, aged 19 years, strong, sturdy physique. Hæmoptysis three months ago, temperature raised one degree each night, and the physical signs limited to the right apex above the clavicle; in fact, a typical example of Class I. in Turban's classification. There were no tubercle bacilli found. After 12 injections of tuberculin no signs or symptoms could be detected. She has gained 8 pounds, cough has disappeared, and she has left the hospital apparently cured.

From this series of cases of phthisis pulmonalis, the results of which I will publish in the course of another 12 months, I am convinced beyond any shadow of doubt that a tuberculin prepared from bovine sources has a most marked and curative effect in tuberculous affections of the lung, but my experience teaches me that, first, the patient must have a certain amount of natural resistance to the organism. If this is not present at the time of observation endeavours must be made by feeding and general tonics to raise the resistance somewhat before the tuberculin treatment is commenced. If it is found impossible with the aid of pure air, nutritious food, blood tonics, &c., to improve the resisting power I have come to the conclusion that tuberculin itself will not be of much avail. Secondly, the tuberculous infection must be limited either to one lobe of a lung or to two small areas of two lungs. If the disease has progressed to the formation of cavities and general constitutional infection, tuberculin has little or no lasting effects, although it improves the patient for a time. Thirdly, the age of the patient is of great importance; the younger the patients the more readily do they respond to tuberculin, and I have found that after the age of 50 it is very difficult to produce good effects with it, although it is quite common, of course, to see patients of that age recover from an early infection of tubercle of the lungs. Fourthly, if there is any concurrent disease, such as kidney trouble, tuberculin seems to have little or no effect.

I intend to continue the treatment for another 100 cases and I will hope to have the pleasure of reporting to you on a future occasion on the total results. At present I am quite certain that every early case of phthisis under suitable conditions should be inoculated with bovine tuberculin.

TUBERCULOUS GLANDS.

Twenty-three cases of tuberculous glands of the neck and other parts of the body have been treated with tuberculin, with, in many instances, the most extraordinary results. Several cases of extensive disease, especially when localised in the neck, have completely recovered. The glands are noticed first of all to become softer, the peri-adenoid tissue seems to become more flaccid and less inflammatory, and the glands themselves rapidly diminish in size to vanishing point. I have noticed, however, that where there is a tendency to suppuration the tuberculin has no good effect and there is nothing for it but either to incise the glands or remove them altogether. In two instances of inflammatory glands where suppuration was threatening tuberculin seemed rather to increase the swelling than diminish it, so that from my experience of treating glands I would say that tuberculin is only indicated where the glands are enlarged and not caseating or suppurating.

LUPUS.

Twenty-four cases of lupus have been treated in the hospital, and it is here that the very best results of tuberculin are obtained. All stages of the disease seemed to respond rapidly to injections, and in all the cases in which I have used tuberculin, without any other treatment such as scraping or medication, the ulcerated surface has healed with a firm cicatrix and in only two instances so far has the disease recurred.

TUBERCULOUS JOINTS.

Twenty-seven cases of tuberculous joints, mostly of a chronic or subacute variety, have been inoculated; 15 diseases of the knee, 8 of the hip, and 4 of other joints. The cases where the best results were obtained were those in which there was some suppuration or sinus directly leading down to tuberculous disease. In the great majority of cases the suppuration ceased first and then the sinus closed. In cases of pulpy disease of the joints there was in many instances marked diminution of the size of the joints with absence of inflammation and more movement. I have not yet seen any case where fixed or ankylosed joints have been benefited.

TUBERCULOUS PERITONITIS.

Eight cases of tuberculous peritonitis have been treated; 4 of the plastic or dry variety and 4 associated with fluid in the abdomen. Every one of the cases has recovered and all have been discharged well after 12 injections each of tuberculin. I consider that tuberculin is an absolute specific in cases of tuberculous peritonitis where the disease is confined to the abdomen.

TUBERCULOUS MENINGITIS.

This, the most terrible of all diseases that we are called upon to treat, may possibly be deprived of its terrors by timely inoculation of tuberculin. Unfortunately, as a rule, in hospital practice the cases do not come until the disease is well advanced or where there is some intercurrent tuberculous lesion. In two cases of apparent tuberculous meningitis with all the classical signs the symptoms entirely disappeared after four injections of tuberculin and both children made rapid recovery. In other two instances tuberculin had no effect and the children died. Of course, it is impossible to be sure that the first two cases were of a tuberculous nature, as tubercle bacilli could not be recovered by lumbar puncture, but I have no doubt myself that they were.

TUBERCULOUS ABSCESSES AND SINUSES.

Eighteen cases were treated. In 13 of them no definite good results were obtained as they were of a chronic nature, but in five cases the sinuses closed and the patients soon got fat and apparently well.

The whole of these 104 cases of surgical tuberculosis have been, of course, treated by Koch's tuberculin R., which, as you know, is manufactured from tubercle bacilli obtained another cast as large as the first and a good deal of mucopurulent expectoration. The apex immediately returned nearly to its former position and was felt half an inch *inside* the left nipple line. As before, the whole left side became resonant, vocal resonance returned, the breath sounds became audible, and were accompanied with some rhonchus and crepitation. At the base behind, as before, there was still some dulness and the voice and breath sounds remained absent. The child was greatly relieved and slept peacefully afterwards for some time. In the course of the next few days the same series of events recurred, the heart gradually passed out again, dyspnœa and duskiness recurred, until on the 28th another cast of the same size and character as the others was coughed up with similar relief to the patient and with the return of the heart to its normal position. However, a few hours later it was evident that another cast was forming with considerable rapidity, for the heart was moving outwards again and the other physical signs were returning, and at midday on Feb. 1st another large cast appeared. On the 3rd several small casts were coughed up and on the 7th a large one, each event being accompanied by the same changes in physical signs as have been described. Up to this time the temperature had been very unstable, rising frequently to 103° and being generally at its highest just before the cast was expectorated. From the 7th convalescence proceeded without interruption. The temperature remained normal or subnormal. The heart continued in its normal place and the patient looked well. She was kept in the hospital for some time largely as a matter of charity and was discharged on May 7th perfectly well, with the heart and lungs in their normal position and without any physical signs in the chest. The casts were examined microscopically and bacteriologically but without any positive result.

The case is an ordinary one of plastic bronchitis and except for the size of the casts does not present any remarkable features. The point of interest is *the displacement of the heart and complementary dilatation of the opposite lung* which followed on the collapse of the affected lung, changes which could hardly have been greater with pneumothorax of the right side. I have once before observed this in a case of extensive broncho-pneumonia of the left lung in a small child, the apex beating half an inch outside the left nipple line and returning to its normal place as the collapse passed off. I have not met with any account of a similar case to the present, which therefore seems worth recording. Some considerations of physiological interest arise out of it. The processes by which the air is absorbed from the air vesicles on collapse or from the pleura in pneumothorax are not fully understood. So far as the O and CO_2 are concerned, these gases exist in the blood partly in solution and partly in loose chemical combination. So that we may fairly suppose that they are removed in these ways. The N presents greater difficulties, being so inert a chemical body. Yet it, too, is removed and often with considerable rapidity.

The forces under which the gases are removed are greater than the elasticity of the lung—i.e., 6–8 millimetres of Hg—otherwise there would be a tendency for air to collect spontaneously in the pleura, and this does not occur. But this case shows that the forces must be much greater than this, for they were sufficient to cause the opposite lung to expand to the maximum. No doubt the violent coughing increased the forces of expiration very considerably and thus favoured absorption during the time of coughing, but in the intervals between the attack of coughing the forces at work would have to be equal to the elastic tension of the lung in its condition of exaggerated stretching, which can hardly be less than 10 millimetres of Hg or 5 inches of water and is probably more, and it must be against this resistance at least that absorption of the air took place.

Wimpole street, W.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—A quarterly meeting of the Royal College of Physicians of Edinburgh was held on Feb. 4th, Dr. C. E. Underhill, the President, being in the chair. Theodore Charles MacKenzie, M.B. Edin., F.R.C.P. Edin., was introduced and took his seat as a Fellow of the College. Patrick Hehir, M.D. Brux., M.R.C.P. Edin., Lansdowne, India; and Harold Sherman Ballantyne, M.B., C.M. Edin., M.R C.P. Edin., Dalkeith, were admitted by ballot to the Fellowship of the College. Lindsay Stephen Milne, M.B., Ch.B. Edin., Montrose, was admitted by ballot to the Membership of the College after examination. The Registrar reported that since the last quarterly meeting 27 persons had obtained the Licence of the College by examination.

AN ARTIFICIAL "AIR-WAY" FOR USE DURING ANÆSTHETISATION.

BY FREDERIC W. HEWITT, M.V.O., M.A., M.D. CANTAB.,
ANÆSTHETIST TO HIS MAJESTY THE KING; PHYSICIAN-ANÆSTHETIST TO ST. GEORGE'S HOSPITAL; CONSULTING ANÆSTHETIST AND EMERITUS LECTURER ON ANÆSTHETICS AT THE LONDON HOSPITAL.

ON several previous occasions, not only in the columns of THE LANCET but elsewhere, I have endeavoured to establish the proposition that in most of the cases in which difficulties arise during general anæsthesia these difficulties are directly dependent upon mechanically obstructed breathing and that this condition, occurring as an incident, introduces into administrations an auto-asphyxial element the true nature of which is frequently misunderstood. It has been pointed out that whilst there are many different varieties of mechanically obstructed breathing—i.e., many different ways in which the respiratory pump may be thrown out of gear independently of any defect in the nerve energy at its disposal—these varieties are capable of being arranged in two main groups. In Group 1 we have obstructive states dependent upon the operation of causes *within* the upper air-passages, and in Group 2 we have obstructive states dependent upon the operation of causes *external* to those passages. As an example of obstructed breathing of the former kind may be mentioned that arising from altered position, spasm, or swelling of the tongue. As an illustration of mechanically impeded breathing of the latter kind, that dependent upon spasm of the external respiratory muscles may be cited. On the present occasion I propose to deal only with the treatment of certain of the obstructive conditions of the first of these two groups and to confine my remarks to cases in which the respiration of semi-anæsthetised or anæsthetised patients becomes partially or completely obstructed owing to occlusion of the air-tract *above the larynx*.

Were it customary, as in physiological experiments, to introduce anæsthetic gases and vapours into the pulmonary passages through a tracheal cannula the text-book descriptions of the clinical phenomena of incipient and complete general surgical anæsthesia would markedly differ from those with which we are now familiar. Under such circumstances we should obtain far more equable results in our administrations and there would be much less intercurrent respiratory disturbance. But as it is necessary in surgical practice to introduce anæsthetics through the ever-varying nasal and oral passages this smoothness in anæsthetisation cannot be depended upon. The upper air-passages of all subjects are liable to alterations in their conformation and calibre during general anæsthesia. This is specially noticeable in certain subjects, e.g., the thick-set and plethoric, whose upper air-passages are naturally narrow; in certain postures, e.g., the Trendelenburg, in which the tongue gravitates towards the palate; and in certain operations, e.g., rectal, which have a tendency reflexly to produce spasmodic tongue retraction. Everyone who has paid much attention to the clinical aspects of general anæsthesia knows how frequently he has to adopt some means for preserving a free air-way. In some cases the jaw must be pressed forwards or the chin pulled up continuously; in others, a mouth-prop adjusted to meet the special peculiarities of the case is required; whilst in others again it is necessary to apply tongue forceps in order to insure free breathing.

The question here presents itself: Should anæsthetic gases and vapours be administered through the oral or through the nasal passages? It is interesting that the natural tendency towards nasal as opposed to oral respiration persists in a marked and often in an inconvenient degree during general anæsthesia. Even though a patient, obeying instructions, commence to breathe orally he will tend, as anæsthesia deepens, towards purely nasal respiration, and this nasal respiration frequently proves inadequate. Whilst nasal breathing is undoubtedly of paramount importance in everyday life it is, as a rule, inferior to oral breathing during the induction and maintenance of general anæsthesia. Suffocative sensations during induction are generally due to nasal respiration, the nasal passages being of insufficient calibre to allow of that quantity of oxygen reaching the lungs per minute which is essential to full blood oxygenation, and hence to the patient's comfort during incipient anæsthesia. It is true that when anæsthesia has become established nasal respiration may in arriving at the conclusion that the patient was suffering from one of the less common types of this affection, the motor nerve-supply of almost the whole muscular system of the trunk as well as that of the limbs being affected in greater or less degree.

THE BACTERIOLOGICAL INVESTIGATION.

Four specimens of the patient's cerebro-spinal fluid were obtained by lumbar puncture on the following dates: Specimen I. on Nov. 22nd, 1906; Specimen II. on Dec. 14th, 1906; Specimen III. on March 25th, 1907; and Specimen IV. on April 17th, 1907. The fluid was clear when withdrawn, but on standing threw down a small greyish sediment which microscopically consisted of lymphocytes.

Cytological examination of the cerebro-spinal fluid.—The deposit obtained on centrifugation of the fluid apparently consisted entirely of mononuclear cells (lymphocytes); no polymorphonuclear leucocytes were seen. In this respect, it may be noted, the fluid resembled that obtained by Geirsvold[1] from 12 cases occurring during an epidemic of acute poliomyelitis which happened in Norway in 1905. Geirsvold found that the deposit from the spinal fluid in his cases consisted chiefly of mononuclear cells and very rarely contained any polymorphonuclear leucocytes.

Bacteriological examination of the cerebro-spinal fluid.—A micrococcus with an obvious arrangement in pairs was recognised in stained preparations of the fluid drawn off by lumbar puncture on Nov. 22nd and on Dec. 14th, but could not be found in the specimens of the fluid which were drawn off on the two later dates. In most of the cover-glass preparations made from the two earlier specimens of fluid a few widely scattered diplococci could be distinguished unmistakeably; in one or two observed instances two pairs were grouped as tetrads. The cocci were of comparatively large size and in this respect were equally comparable with micrococcus pneumoniæ; there was some indication of a capsule, but this was not so distinct as it was with the diplococci which were found in the cerebro-spinal fluid of the experimental rabbits. The diplococci were always found free in the fluid, no intracellular forms occurred. We were unable to obtain a culture of this diplococcus on artificial media; media of every description were inoculated with the fluid and incubated both aerobically and anaerobically, but in no instance was growth of any kind obtained.

Animal experiments.—Altogether nine rabbits were inoculated with cerebro-spinal fluid obtained from the case, seven being inoculated intracranially, one intraperitoneally, and one subcutaneously. Sundry other rabbits were inoculated intracranially with an emulsion of cerebro-spinal substance and fluid from certain of the first series of experimental animals. The intracranial inoculations were carried out by means of a fine hypodermic syringe through a small trephine opening in the frontal region; in the case of the first series of animals a cubic centimetre of cerebro-spinal fluid from the patient was injected into the subdural space. One animal (Rabbit 4) died as the direct result of the operation; all the others apparently recovered quickly and completely from the immediate effects of the operation. The results of our experiments were as follows.

Rabbit 1, inoculated from the specimen of spinal fluid drawn off on Nov. 22nd, was found dead on the twenty-second day afterwards and diplococci similar to those identified in the patient's fluid were found in its spinal sac. This animal had not been under close observation during the week which preceded its death and consequently we are unable to say whether there had been any paralyses.

Two rabbits (Nos. 2 and 3) were inoculated with an emulsion of the cerebro-spinal substance and fluid of Rabbit 1. Rabbit 2 died on the eleventh day after the inoculation and Rabbit 3 was killed under chloroform on the following day. Both animals were apparently quite well up to the time of death; no cause for the death of the former could be found, and the appearances in each after death were quite normal, nor were any micro-organisms found in the cerebro-spinal sac of either.

Two rabbits (Nos. 4 and 5) were inoculated with the specimen of fluid drawn off on Dec. 14th. Rabbit 4 died within 24 hours from an intracranial hæmorrhage the result of the operation. Rabbit 5 remained apparently well for more than six weeks, but on the fiftieth day after inoculation it was noticed that the hind limbs were partially paralysed. Two days later the hind limbs were completely paralysed and the fore limbs partially paralysed; the animal meanwhile had been eating well and, except for the paralysis, was not obviously ill. Death occurred on the fifty-third day after the inoculation, and a fair number of diplococci were found in the animal's cerebro-spinal fluid.

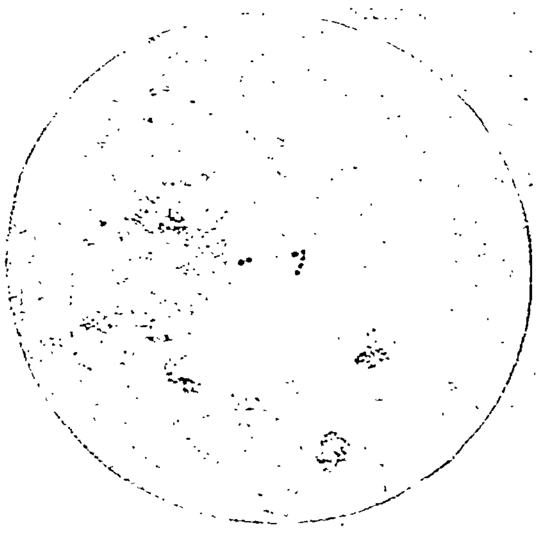
Two rabbits (Nos. 6 and 7) were inoculated with an emulsion of the cerebro-spinal substance and fluid from Rabbit 5. Of these, Rabbit 6 was killed under chloroform on the forty-first day after the inoculation, the animal being then apparently healthy, and no diplococci could be found in the cerebro-spinal sac. Rabbit 7 was found to have complete paralysis of the hind limbs on the forty-seventh day after the inoculation, followed rapidly by a paralysis of the fore limbs which was very plainly obvious on the forty-ninth day. The animal was killed on the fiftieth day after the inoculation and diplococci were found in the cerebro-spinal sac.

Rabbits 10 and 11 were inoculated with an emulsion of the cerebro-spinal fluid and substance from Rabbit 7. One died on the fourth day after inoculation, but the cause of death could not be ascertained; the other did not suffer from any apparent ill-effects and was alive and well four months afterwards.

Diplococci had been seen in the specimens of spinal fluid from the patient from which these rabbits had been inoculated, but none were seen in the specimens withdrawn on March 25th and April 17th, 1907, with which the remaining animals (Rabbits 8, 9, 12, 13, 14, and 15) were inoculated, and none of these animals suffered apparently from the inoculation.

In the case of each animal that either died naturally or was killed under chloroform a careful examination was made of stained specimens of the cerebro-spinal fluid, the heart blood and the juice from the spinal cord, the spleen, and other organs, but in no case were any diplococci found except in those instances in which we have noted its presence in the cerebro-spinal fluid. Culture media of the most varied description were inoculated also from the cerebro-spinal fluid, the heart blood, and various tissue juices in every case. But except for occasional growth, which was obviously due to accidental causes, all the media used remained sterile on incubation; and, in particular, no growth of any kind was obtained on any of the media inoculated with the cerebro-spinal fluid from Rabbits 1, 5, and 7, in which we had been able on microscopical examination to demonstrate clearly the presence of the diplococci.

Except in the case of the rabbit which died from an accident of the inoculation operation, and Rabbits 14 and 15, which died from coccidiosis, no macroscopic morbid change was found after death—in every case the meningeal membranes appeared perfectly natural and healthy, nor was any excess or other abnormality of the cerebro-spinal fluid noticed.



Microphotograph showing cocci in cerebro-spinal fluid of Rabbit No. 1 dying on twenty-second day after inoculation.

Unfortunately, no adequate histological examination of the spinal cords of the rabbits was made. Small portions of the cervical, dorsal, and lumbar cord from Rabbit 7 only were

CASES OF OPERATION FOR ACUTE APPENDICITIS.

TABLE I.—EARLY OPERATIONS (*i e., within 48 hours*). PRIVATE CASES.

No.	Under the care of—	Date of operation.	Sex.	Years of age.	Approximate duration of symptoms	Pulse and temperature at time of operation.		Suppuration.	Removal of appendix.	Condition of appendix.	Result.
						P.	T.				
	Dr. F. R. Mallett (Bolton).	1906. Feb. 1st.	M.	29.	48 hours.	88	100°	Localised.	Yes.	Small perforation; inflamed and very friable; three concretions.	Recovered.
2	Dr. Helene Goldberg-Saul (Withington).	June 18th.	M.	19	19 ,,	110	103°	Absent.	,,	Lumen completely occluded, distal portion distended with pus; three concretions.	,,
3	Mr. J. T. Finlay (Rawtenstall).	July 14th.	M.	7	42 ,,	124	105°	,,	,,	Mucous membrane inflamed; two patches of superficial ulceration.	,,
4	Dr. D. Macmillan (Prestwich).	,, 21st.	F.	30	48 ,,	108	104°	,,	,,	Intensely injected, coated with flaky lymph; mucous membrane ulcerated.	,,
5	Mr. R. A. Shelton Daly (Manchester).	Nov. 3rd.	M.	38	42 ,,	120–130	—	Localised	,,	Gangrenous and perforated.	,,
6	Mr. J. T. Finlay (Rawtenstall).	,, 19th.	F.	24	18 ,,	118	99°	Absent.	,,	Intensely congested.	,,
7	Dr. D. Macmillan (Prestwich).	,, 21st.	F.	25	24 ,,	96	100°	,,	,,	Acutely inflamed, and roughened from deposit of lymph.	,,
8	Mr. G. M. Drury (Cheadle Heath).	1907. Jan. 13th.	F.	20	42 ,,	120	101°	Localised.	,,	Gangrenous and perforated; concretion.	,,
9	Dr. A. A. Mumford (Chorlton-cum-Hardy).	,, 15th.	M.	24	12 ,,	108	100°	Absent.	,,	Intensely congested and of purplish colour, becoming gangrenous; distended with dark fluid and on point of rupture; concretion.	,,
10	Mr. A. P. Walker (Hadfield).	Feb. 9th.	M.	54	43 ,,	88	99·6°	Localised.	,,	Small perforation, with extensive patch of gangrenous mucous membrane; concretion.	,,

Number of cases 10. Died, 0. Mortality, *nil.*

TABLE II.—INTERMEDIATE OPERATIONS (*i.e., third to fifth day*). PRIVATE CASES.

1	Dr. J. Mason (Windermere).	1906. Feb. 19th.	M.	8	5 days.	116	101°	Encysted.	No.	Not seen.	Recovered.
2	Mr. J. T. Finlay (Rawtenstall).	April 16th.	F.	20	3 ,,	140	99·6°	General.	,,	,,	Died.
3	Dr. D. J. Mackenzie (Glossop).	Oct. 3rd.	F.	25	3 ,,	120	104°	Localised.	Yes.	Gangrenous and perforated; concretion.	Recovered.

Number of cases, 3. Died, 1. Mortality, 33 per cent.

TABLE III.—LATE OPERATIONS (*i.e., after fifth day*). PRIVATE CASES.

1	Mr. Edmund Lee (Manchester).	1906. March 28th.	F.	8	12 days.	—	—	Encysted.	No.	Not seen.	Recovered.
2	Dr. G. F. Waterston (Bolton).	May 1st.	F.	23	14 ,,	110	101·2°	,,	,,	,,	,,

Number of cases, 2. Died, 0. Mortality, *nil.*

and "late" stages no fewer than eight died, giving a mortality of 30 per cent. Five private patients were operated upon during the "intermediate" and "late" stages with one death, giving a mortality of 20 per cent. (Tables II. and III.). If all the cases are considered together the result is as follows:—

	Cases.		Died.		Mortality.
"Early" operation	10	...	0	...	*Nil.*
"Intermediate" operation ...	17	...	8	...	47 per cent.
"Late" operation	14	...	1	...	7 ,,
Total	41	...	9	...	22 ,,

It is worthy of note that in eight out of the nine fatal cases there was general suppuration throughout the peritoneal cavity at the time of operation. Judging by the condition found in four of the cases recorded in Table I (Cases 1, 5, 8, and 10), where there was localised suppuration and where success attended the "early" operation, it is probable that a similar result would also have followed earlier surgical intervention in the fatal cases—that is to say, if the peritoneal cavity had been opened and drained before the suppuration had spread and become general. In the remaining fatal case (Table IV., Case 14), though suppuration had not taken place, the appendix was becoming gangrenous at the time of operation; in this instance death was due to infective endocarditis with pericardial effusion.

As regards the indications for early operative interference in acute appendicitis, the difficulty that we often meet with at the onset is that it is impossible to foretell the course which the inflammatory process will take—viz., whether the attack will be of the simple or of the destructive variety. For it is a recognised fact that the early symptoms may be of a very mild character, even when grave lesions are taking place in the appendix.

The temperature and pulse-rate bear no constant relation to the severity of the attack. They may both be increased in the simple form, while in the destructive variety—even when perforation and gangrene are impending or have taken place—there may be very little rise in either (as in Table I., Case 10), or they may remain normal or even become subnormal. A rapid pulse, however—e.g., over 100, and especially if above 120, in the early stage—is always suggestive of serious mischief and points to a probable termination in suppuration. The same applies to a high temperature—e.g., 103° or the examination of the fluid removed by lumbar puncture in 10 cases of anterior poliomyelitis; nine of the cases were examined by bacteriological methods, and the pneumococcus was found in two cases and the meningococcus in a third. Looft and Dethloft[12] isolated from the spinal fluid of two cases an organism which is described as resembling Heubner's type of meningococcus. And, finally, Engel[13] obtained staphylococcus albus on media inoculated with the spinal fluid of a boy with acute anterior poliomyelitis, disease of the middle ear, and osteo-myelitis of the clavicle. To these bacteriological observations mentioned by Looft may be added the experience of Barnes and Miller[14] who found staphylococcus pyogenes citreus and staphylococcus albus in a case examined after death.

The results of bacteriological work so far are not of any particular value for the elucidation of the causation of cases of acute poliomyelitis; in some cases it is highly probable that the organism obtained on culture media came from accidental contamination during the bacteriological procedure. In other cases question arises as to clinical diagnosis, and in no case is any evidence brought forward that the organism obtained in culture had any causative relationship to the disease.

The results obtained by Geirsvold, on the other hand, were consistent and afford the strongest presumptive evidence that he was successful in isolating a diplococcus which stood in causative relationship to the disease which was under investigation. Geirsvold examined the cerebro-spinal fluid obtained either by lumbar puncture during life or after death from cases of the epidemic disease which has recently prevailed in Norway. It does not appear how many cases were examined, but in 12 cases Geirsvold obtained in pure culture a diplo- or tetro-coccus which readily produced chains of four or six elements when growing in nutrient broth.

On solid media the growth of the organism was slow at first and scanty, resulting in sparsely scattered, small, greyish colonies having the appearance of dewdrops, but in subsequent subcultures a more vigorous growth was obtained. After growing for some time on agar the colonies acquired a toughish consistence; in nutrient broth the growth formed a coherent sediment; in peptone water growth was scanty, and in this medium "degenerate" forms of the micrococcus were seen. Some growth was obtained on potato and in milk, the latter medium being coagulated after some days. Growth was obtained occasionally on gelatin and then the medium became liquefied. The organism stained by Gram's method. The organism was pathogenic for mice; some of the animals inoculated died within 24 hours and in some cases showed signs of muscular paralysis before death; other mice appeared to recover from the inoculation but developed paralysis later. Rabbits also were susceptible, sudden paresis of the hind limbs developing after a prolonged incubation period. Geirsvold notes that in order to obtain cultures of the micrococcus large quantities of the spinal fluid must be incubated. He very rarely obtained cultures after the tenth or twelfth day of the disease, although diplococci could be seen in the fluid withdrawn from the spinal sac, an experience which has a bearing on our own failure to obtain any growth of the organism which could be seen in spinal fluid withdrawn on about the twelfth day after the onset of illness and again later.

CONCLUSIONS.

It appears to us that Geirsvold's investigations have established beyond question the existence of a specific infective disease of which acute poliomyelitis is a frequent and prominent, but not essential, feature. And we believe that the case which we now record represents a sporadic case of the disease which Geirsvold investigated under epidemic circumstances. From the somewhat scanty information at our disposal it would appear that this specific disease has no clearly distinguishing primary features to enable one to differentiate it by its clinical symptoms from many other febrile conditions of probably infective origin which are frequently met with in practice but which may not have sufficiently distinctive symptoms to enable a definite diagnosis to be arrived at. And so whilst the serious complication of acute poliomyelitis when it has occurred has been at once recognised, the primary disease has not been differentiated hitherto but has in fact usually been altogether overlooked. That the disease is not confined to man is suggested by an epidemic of some 160 cases of what appears to have been acute anterior poliomyelitis which has been recorded by Dana,[15] and in which cases of paralysis were observed amongst lower animals in the locality in which the human cases occurred.

It would be unprofitable, again because of the insufficient information at our disposal, to attempt to discuss the exact pathology of the acute poliomyelitis which is one of the results of this infection. Neither our own experience nor Geirsvold's much more extensive investigation throws any light upon the question as to whether the affection of the nervous system is merely a casual incident of what may be termed broadly a general infection or whether, having gained an entrance into the tissues, the infecting parasite has, as diplococcus intracellularis of Weichselbaum apparently has, a special tendency to locate itself in the cerebro-spinal sac. Nor are we at present in a position to consider whether the poliomyelitis is due to a direct and localised action of the diplococci which are seen in the spinal fluid or whether it results from the action of toxins circulating in solution in the lymph or blood, which may have an affinity, such as that of the toxins of the tetanus bacillus, for nerve-cell substances. It must not be forgotten that although the diplococcus has hitherto been recognised only in the cerebro-spinal fluid there is no reason for assuming that it is specially localised in the sac of the central nervous system. We failed in the case of our experimental rabbits to obtain cultures of the organism from either the cerebro-spinal fluid or from the blood and other tissue juices, and the fact that the organism was identified in very small numbers only in the almost clear cerebro-spinal fluid in which its recognition would be comparatively easy did not preclude its existence in the blood, where its presence would be much more difficult of demonstration by merely microscopic methods without corroborative cultivation experiments.

In conclusion, we would suggest that there is not sufficient reason for assuming that acute poliomyelitis is always a result of this particular diplococcal infection. The symptoms by which acute poliomyelitis is recognised in clinical practice are the consequences of a constitutional alteration of certain cells of the central nervous system which causes an impairment of their functional efficiency. That this constitutional alteration is necessarily produced by only one specific cause appears to us to be highly improbable. We think rather that it is probable that the cell changes which result in the symptoms of acute poliomyelitis may be caused also by the toxins produced in other infective processes, and we may refer to the experience of so good an observer as Trevelyan[16] who found that out of 50 cases of infantile paralysis which he had treated the symptoms had followed immediately on measles in two cases, in one case had come on after typhoid fever, and in another case after acute rheumatic fever.

THE THERAPEUTIC USES OF NORMAL SERUM.

BY E. C. HORT, B.A., B.SC. UNIV. PARIS, M.R.C.P. EDIN.

IN THE LANCET of Dec. 21st, 1907, p. 1744, I mentioned that during the last 12 months I had been treating with most encouraging results a number of morbid conditions by the administration of normal serum. Amongst the diseases that I have treated, and am proposing to treat, in this way are the following conditions: gastric and duodenal ulcer, with and without hæmorrhage; chlorosis and other forms of anæmia; hæmophilia; purpura hæmorrhagica; tuberculous peritonitis; hæmoptysis; ulcerations of all kinds; pulmonary œdema; pneumonias, &c. In addition to these Dr. Arthur Latham has, at my suggestion, employed normal serum in a number of similar and other cases and has most kindly allowed me access to his notes.

My attention was first drawn to the subject by the work of Dr. Emil Weil of Paris on the treatment, by fresh animal serums, of hæmophilia and allied conditions, and by Dr. Perthes's observations on hæmophilia. It appears that these observers, believing that a deficiency in coagulation power was an important factor in the blood in such diseases as hæmophilia, sought to remedy this by giving an artificial supply of fibrin ferment. With this object Weil gave intravenously or subcutaneously injections of various animal cases, even when the initial symptoms are of a mild character and point to the attack being of the "simple" form, for it is never possible to predict with certainty what course the inflammatory process will take, and there is always the risk of a termination in suppuration. Supposing, however, that this does not take place and the appendix is allowed to remain, it will probably be left more or less thickened and contracted or bound down by adhesions, and therefore in such a condition that sooner or later the attacks will almost certainly recur. If all cases of appendicitis are operated upon in the early stage, as soon as the diagnosis is established, I believe that the danger will not be any greater than that which attends removal of the appendix in the quiescent period following one or more attacks. In the latter circumstances appendectomy is frequently a complicated operation owing to the presence of adhesions, the result of the previous attacks, and the appendix may be so fixed and buried in these adhesions that its recognition, as well as its removal, are often attended with considerable difficulty.

As regards the after-treatment in the cases recorded in the accompanying tables drainage was employed in every instance and even when suppuration had not taken place a small tube was left in the wound for 36 or 48 hours, perhaps rather as a safeguard than because it was absolutely necessary. When there was an encysted abscess or localised suppuration larger tubes and strips of gauze were inserted and a counter-opening was usually made in the loin, or through the vagina in females, when the pus tracked down into the pelvis. Care was always taken to disturb the parts around the area of suppuration as little as possible, so as not to break down any protective adhesions which might be forming. When the suppuration was general one or more openings were also made in the middle line or on the opposite side of the abdomen; and under the same conditions Fowler's position, and Murphy's method of saline injections into the rectum, were employed in some of the cases.

CAVERNOUS NÆVUS: TREATMENT BY METALLIC MAGNESIUM.

By JOHN A. C. MACEWEN, M.B., C.M., B.Sc. GLASG., F.F.P.S. GLASG.,

SURGEON TO THE ELDER HOSPITAL, GOVAN; ASSISTANT SURGEON, GLASGOW ROYAL INFIRMARY; SENIOR ASSISTANT TO REGIUS PROFESSOR OF SURGERY, UNIVERSITY OF GLASGOW.

MY attention was first directed to the above mode of treatment by a paper on the subject by my friend Dr. Gavin McCallum of Geelong, Australia, in which he reported one or two cases in which highly satisfactory results were obtained by the method to be described.

The patient, a weakly girl, 15 months old, was first seen by me at the Elder Hospital in May, 1905, suffering from a large cavernous nævus of the right side of the face which occupied the whole substance of the cheek, being covered superficially by a layer of thin, white skin resembling that which is seen covering scars which have stretched, while internally it projected slightly into the cavity of the mouth, being covered by the mucous membrane which appeared healthy and of normal texture. The tumour was larger than a walnut normally, but increased considerably in size when the patient cried, while it diminished slightly on digital pressure. Slight arterial pulsation was felt. The patient was first operated on in July, 1905, then in January, 1906, and, lastly, in July, 1906, so that a period of six months elapsed between each application. After the first operation the tumour increased in size for a few days succeeding the operation, became firmer, and conveyed a sensation of increased warmth to the touch. It then gradually decreased in size and became distinctly firmer, presenting more definite outline than it previously had done. Similar results followed the other two operations, but after the third operation I was still doubtful as to the entire success of the treatment; the tumour had become distinctly smaller and firmer, but I was still uncertain whether some tumour tissue did not remain. The patient became ill shortly after the third operation, so that I did not see her again until November, 1907—over a year since the third operation—when I again had an opportunity of examining her. I now found that the tumour had entirely disappeared, the cheek presenting, on palpation, a thickening over the site of the tumour, due doubtless to the connective tissue which had formed as a result of the treatment. Not only had no scar resulted from the treatment but the skin over the surface, which it will be remembered was of a very unsatisfactory character when first seen, had slightly improved.

The mode of treatment, which I modified slightly, consisted in preparing several needles out from magnesium ribbon. These were sterilised by boiling and were introduced by pushing with a pair of forceps into the substance of the tumour through a slight puncture in the surface made with a bistoury. The needles were entirely buried in the substance of the tumour, no part being left projecting on the surface, and care being taken to prevent perforation of the mucous membrane on the inner surface. Some six or eight needles were introduced on each occasion into various parts of the tumour, strict asepsis being observed throughout, and the surface operated on was covered by a film of gauze with celloidin to exclude contamination after operation. The magnesium ribbon is a little troublesome to manipulate owing to its being both soft and brittle, but with a little patience these difficulties are overcome. I do not know of any other method which would have yielded an equally satisfactory result in this case, where the tumour was large and situated on the most prominent part of the face where scarring or change of contour would at once attract attention.

The beneficial action which the magnesium needles exert in such cases is probably due to two causes. In the first place, the needles exert a mechanically irritating effect on the walls of the vessels with which they come in contact, a constant movement being kept up both by the pulsation of the little arteries and by movements of the cheek. In consequence of this movement the endothelial lining of these vessels will be abraded and a white thrombus will form; as has been demonstrated by Sir William Macewen to occur when an aneurysm is treated by his method of needling. This is the more important action. In the second place, magnesium, as is well known, is very readily oxidised, and this process of oxidation appears to take place very rapidly in the tissues; indeed, so rapid was the process in the case here reported that it was difficult to detect the presence of the needles in the tissues some three or four days after their introduction. This, of course, is an important point in this method of treatment, as it enables one to bury the needles at the outset, thus permitting rapid healing of the minute surface wound, and the needle is removed after a few days by the oxidising action of the blood and probably the leucocytes. During the oxidising process, however, the magnesium probably causes the formation of small red thrombi, in addition to the white ones mentioned above. The embryonic fixed tissue cells in the white thrombi will rapidly become converted into adult connective tissue, while the red thrombi will to some extent be replaced by similar fibroblasts which will also become converted later into adult connective tissue. The connective tissue so formed will occlude the vessels in connexion with which it grew, and, by its subsequent contraction, will obliterate the vessels in its neighbourhood. Thus the ultimate result is occlusion of all the vessels of the tumour by fibrous tissue formation, which ultimately will greatly diminish in bulk.

A NOTE ON THREE CASES OF PLAGUE TREATED BY YERSIN'S SERUM.

By AUSTIN C. DIXON, L.R.C.P. LOND., M.R.C.S. ENG.,

CHIEF MEDICAL OFFICER OF THE ANTOFAGASTA HOSPITAL.

IN the fourth Croonian lecture by Professor W. J. R. Simpson, reported in THE LANCET of July 27th, 1907, the following remarks are made: "Great expectations were raised on the introduction of Yersin's serum but they have not been realised and a serum has yet to be discovered which while being germicidal in its action also possesses antitoxic properties." I must acknowledge that up to now widely different conditions as, for example, hæmophilia and tuberculous caseation of lung or other tissue. But it is not impossible that there is a common basis of autocytolysis in these and in a vast number of other conditions characterised by destruction of epithelial, endothelial, hæmic, or other cell, and that such autolysis can be inhibited by normal serum. It appears from the results that I have obtained by the oral administration of serum that subcutaneous or intravenous injections are not at all necessary. I found at the same time that T.R. tuberculin and antistaphylococcal vaccines and other vaccines may be given in the same way, and apparently the clinical results are in no way impaired. This will of course require confirmation. Since writing this paper I learn that in Australia a number of diseases have been treated by Dr. Montgomerie Paton with antidiphtheritic and other serums administered by the mouth. The cases he has published seem to confirm amply the value of normal serum-therapy that I have independently arrived at.

PLASTIC BRONCHITIS

IN A GIRL, AGED 11 YEARS, THE SEVENTH ATTACK IN FOUR YEARS, THE FIRST OCCURRING AT THE AGE OF SEVEN YEARS: EXTREME DISPLACEMENT OF THE HEART AND MEDIASTINUM, PRODUCED BY COLLAPSE OF THE LUNG, DISAPPEARING WITH EXPECTORATION OF THE CAST, BUT RECURRING AS EACH FRESH CAST FORMED.

BY SAMUEL WEST, M.D. OXON., F.R.C.P. LOND.,
PHYSICIAN TO, AND LECTURER ON MEDICINE AT, ST. BARTHOLOMEW'S HOSPITAL.

A GIRL, aged 11 years, was admitted into St. Bartholomew's Hospital with plastic bronchitis. The first attack was at the age of seven years; since then she had had six attacks, this being the seventh. She had been in this hospital for the previous three attacks. The present attack began on Jan. 14th, 1907, with headache and cough. On the 15th she was at school, but on the 16th she was too unwell to leave bed. She had slept badly, had much headache, vomited several times, complained of a "lump in the throat," and brought up some blood-stained sputum. The patient was a well-developed child, but she looked ill, was somewhat dusky, had a tight cough, and expectorated a little blood-streaked sputum. The temperature was 99° F., the pulse was 140, and the respirations were 36. She complained of feeling a "lump in the chest" in the upper part of the left side in front. The percussion note was greatly impaired over the whole left side, back and front, and at the base behind was almost dull. The vocal resonance and breath-sounds were absent everywhere except in the left interscapular space, where they were somewhat exaggerated. The stony dulness here almost suggested fluid, but there was no displacement of the heart to the opposite side; on the contrary, the apex beat was an inch to the left of the left nipple line in the fifth space and the resonance of the right lung extended across the sternum and reached an inch to the left of the edge of the sternum along the third rib. Corresponding with this the respiratory sounds changed from the somewhat exaggerated sounds of the right lung to the defective sounds of the left. It was evident that the left lung was contracted and the right expanded. This was thought to be due to collapse of the left lung consequent on the occlusion of the left main bronchus by a cast. On Jan. 18th the condition was much the same but the breath was shorter and the duskiness more marked. On the 19th, at 4 A.M., a large cast was coughed up two and a half inches long and the stem was nearly one-third of an inch in diameter. It was brought up after much coughing and great distress. The temperature the evening before reached 103° but on the morning after the cast had been expectorated it fell to 99·8°. On the 20th several more pieces of casts of smaller size were brought up along with some muco-purulent sputum. The apex of the heart returned to the left nipple line—i.e., moved two inches towards its proper place. The upper part of the left lung became resonant and the breath sounds there distinct and accompanied with a little crepitation. The base behind, however, continued *in statu quo* with dulness to percussion and absent breath sounds. The patient was now placed upon ten grains of iodide of potassium three times a day. Gradually the physical signs became much as they were on admission, and the heart's apex returned to its former place outside the left nipple line. The patient became more dusky and drowsy, and on the evening of the 22nd she brought up

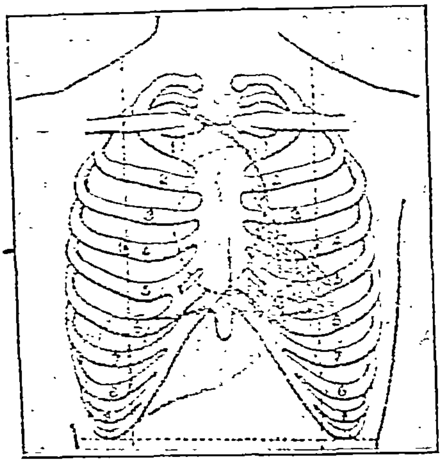

Diagram showing the displacement of organs before the expulsion of the cast.

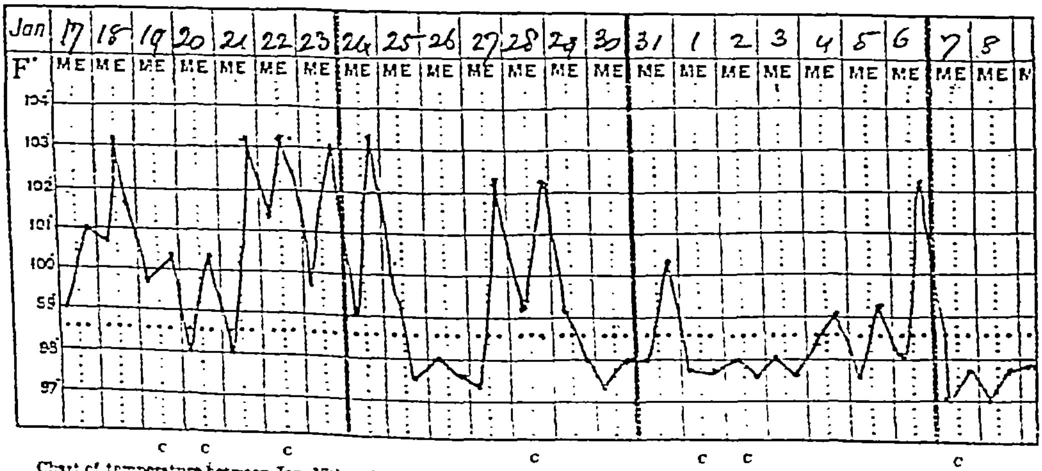

Chart of temperature between Jan. 17th and Feb. 8th. On the dates indicated below by the letter C casts were expectorated.

cases, even when the initial symptoms are of a mild character and point to the attack being of the "simple" form, for it is never possible to predict with certainty what course the inflammatory process will take, and there is always the risk of a termination in suppuration. Supposing, however, that this does not take place and the appendix is allowed to remain, it will probably be left more or less thickened and contracted or bound down by adhesions, and therefore in such a condition that sooner or later the attacks will almost certainly recur. If all cases of appendicitis are operated upon in the early stage, as soon as the diagnosis is established, I believe that the danger will not be any greater than that which attends removal of the appendix in the quiescent period following one or more attacks. In the latter circumstances appendectomy is frequently a complicated operation owing to the presence of adhesions, the result of the previous attacks, and the appendix may be so fixed and buried in these adhesions that its recognition, as well as its removal, are often attended with considerable difficulty.

As regards the after-treatment in the cases recorded in the accompanying tables drainage was employed in every instance and even when suppuration had not taken place a small tube was left in the wound for 36 or 48 hours, perhaps rather as a safeguard than because it was absolutely necessary. When there was an encysted abscess or localised suppuration larger tubes and strips of gauze were inserted and a counter-opening was usually made in the loin, or through the vagina in females, when the pus tracked down into the pelvis. Care was always taken to disturb the parts around the area of suppuration as little as possible, so as not to break down any protective adhesions which might be forming. CAVERNOUS NÆVUS: TREATMENT BY METALLIC MAGNESIUM.

BY JOHN A. C. MACEWEN, M.B., C.M., B.SC. GLASG., F.F.P.S. GLASG.,
SURGEON TO THE ELDER HOSPITAL, GOVAN; ASSISTANT SURGEON, GLASGOW ROYAL INFIRMARY; SENIOR ASSISTANT TO REGIUS PROFESSOR OF SURGERY, UNIVERSITY OF GLASGOW.

MY attention was first directed to the above mode of treatment by a paper on the subject by my friend Dr. Gavin McCallum of Geelong, Australia, in which he reported one or two cases in which highly satisfactory results were obtained by the method to be described.

The patient, a weakly girl, 15 months old, was first seen by me at the Elder Hospital in May, 1905, suffering from a large cavernous nævus of the right side of the face which occupied the whole substance of the cheek, being covered superficially by a layer of thin, white skin resembling that which is seen covering scars which have stretched, while internally it projected slightly into the cavity of the mouth, being covered by the mucous membrane which appeared healthy and of normal texture. The tumour was larger than a walnut normally, but increased considerably in size when the patient cried, while it diminished slightly on digital pressure. Slight arterial pulsation was felt. The patient was first operated on in July, 1905, then in January, 1906, and, lastly, in July, 1906, so that a period of six months elapsed between each application. After the first operation the tumour increased in size for a few days succeeding the operation, became firmer, and conveyed a sensation of increased warmth to the touch. It then gradually decreased in size and became distinctly firmer, presenting more definite outline than it previously had done. Similar results followed the other two operations, but after the third operation I was still doubtful as to the entire success of the treatment; the tumour had become distinctly smaller and firmer, but I was still uncertain whether some tumour tissue did not remain. The patient became ill shortly after the third operation, so that I did not see her again until November, 1907—over a year since the third operation—when I again had an opportunity of examining her. I now found that the tumour had entirely disappeared, the cheek presenting, on palpation, a thickening over the site of the tumour, due doubtless to the connective tissue which had formed as a result of the treatment. Not only had no scar resulted from the treatment but the skin over the surface, which it will be remembered was of a very unsatisfactory character when first seen, had slightly improved.

The mode of treatment, which I modified slightly, consisted in preparing several needles out from magnesium ribbon. These were sterilised by boiling and were introduced by pushing with a pair of forceps into the substance of the tumour through a slight puncture in the surface made with a bistoury. The needles were entirely buried in the substance of the tumour, no part being left projecting on the surface, and care being taken to prevent perforation of the mucous membrane on the inner surface. Some six or eight needles were introduced on each occasion into various parts of the tumour, strict asepsis being observed throughout, and the surface operated on was covered by a film of gauze with celloidin to exclude contamination after operation. The magnesium ribbon is a little troublesome to manipulate owing to its being both soft and brittle, but with a little patience these difficulties are overcome. I do not know of any other method which would have yielded an equally satisfactory result in this case, where the tumour was large and situated on the most prominent part of the face where scarring or change of contour would at once attract attention.

The beneficial action which the magnesium needles exert in such cases is probably due to two causes. *In the first* place, the needles exert a mechanically irritating effect on the walls of the vessels with which they come in contact, a constant movement being kept up both by the pulsation of the little arteries and by movements of the cheek. In consequence of this movement the endothelial lining of these vessels will be abraded and a white thrombus will form; as has been demonstrated by Sir William Macewen to occur when an aneurysm is treated by his method of needling. This is the more important action. In the second place, magnesium, as is well known, is very readily oxidised, and this process of oxidation appears to take place very rapidly in the tissues; indeed, so rapid was the process in the case here reported that it was difficult to detect the presence of the needles in the tissues some three or four days after their introduction. This, of course, is an important point in this method of treatment, as it enables one to bury the needles at the outset, thus permitting rapid healing of the minute surface wound, and the needle is removed after a few days by the oxidising action of the blood and probably the leucocytes. During the oxidising process, however, the magnesium probably causes the formation of small red thrombi, in addition to the white ones mentioned above. The embryonic fixed tissue cells in the white thrombi will rapidly become converted into adult connective tissue, while the red thrombi will to some extent be replaced by similar fibroblasts which will also become converted later into adult connective tissue. The connective tissue so formed will occlude the vessels in connexion with which it grew, and, by its subsequent contraction, will obliterate the vessels in its neighbourhood. Thus the ultimate result is occlusion of all the vessels of the tumour by fibrous tissue formation, which ultimately will greatly diminish in bulk.

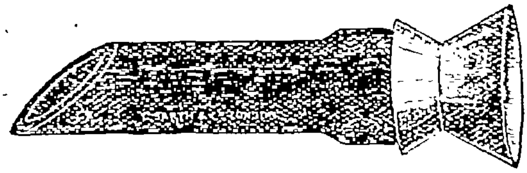
Glasgow.

A NOTE ON THREE CASES OF PLAGUE TREATED BY YERSIN'S SERUM.

BY AUSTIN C. DIXON, L.R.C.P. LOND., M.R.C.S. ENG.,
CHIEF MEDICAL OFFICER OF THE ANTOFAGASTA HOSPITAL.

IN the fourth Croonian lecture by Professor W. J. R. Simpson, reported in THE LANCET of July 27th, 1907, the following remarks are made: "Great expectations were raised on the introduction of Yersin's serum but they have not been realised and a serum has yet to be discovered which while being germicidal in its action also possesses antitoxic properties." I must acknowledge that up to now under certain conditions, be quite satisfactory, these conditions being (1) the existence of spacious nasal channels, and (2) a sufficiently high oxygen percentage in the atmosphere presented to the patient. But it often happens in practice that the nasal passages, either from pre-existing conditions within them, or from causes which have arisen during the administration, do not permit that *free* intake of oxygen by the lungs which is necessary in order that all asphyxial phenomena may be prevented. With such a restricted inlet to the respiratory pump the abdominal and thoracic muscles necessarily become thrown into exaggerated action; and muscular rigidity, cyanosis, dilatation of the pupils, separation of the lids, and even pallor may result. Auto-asphyxia thus insidiously arising is not infrequently mistaken for chloroform overdosage, surgical shock, or other conditions.

In order to secure free and exclusively oral respiration when administering anæsthetics it is necessary (1) to keep the teeth or gums apart; (2) to keep the tongue away from the palate and pharynx; and (3) to block the nasal channels. The little appliance here figured effects this in most cases —not, perhaps, in all, because of the great variations which exist in the conformation of the upper air passages of different subjects. It consists of a circular metal ring, with an internal diameter of half an inch, and with a deep groove in its outer circumference to allow of the ring being held firmly by the teeth. The two flanges which result from the presence of this circular groove or trough are of unequal size, the smaller projecting within the mouth and the larger outside the teeth or gums. From the inner circumference of the ring there also projects into the mouth a short metal collar carrying a portion of indiarubber tubing the free end of which is cut obliquely or whistle-shaped, as shown in the figure. The tubing should have a maximum length of about three and a quarter inches, a clear internal bore of half an inch, and its wall should be sufficiently thick to prevent kinking. By a simple screw adjustment in the collar the rubber tube may, if desired, be removed from the metal ring which will then act as a mouth prop.



The artificial "air-way" is not intended for use in every case. It is principally serviceable in those cases in which respiration is performed with some embarrassment or difficulty owing to the upper air-tract being more or less obstructed. If at the conclusion of the induction period, when the patient should be settling down into smooth and deep anæsthesia, the breathing be laboured and noisy, with sniffing or snorting sounds—if, in other words, the patient be "taking the anæsthetic badly" or "breathing badly"—the jaws should be separated and the whistle-shaped end of the "air-way" passed backwards into the pharynx, so that the oblique opening of the rubber tube faces the laryngeal orifice, and the metal ring adjusted so that it is grasped by the teeth or gums. The substitution of free oral for imperfect nasal or oral respiration will, in the great majority of cases, immediately be followed by slower and quieter breathing, an improvement in colour, and greater muscular relaxation; in fact, by an altogether better type of anæsthesia. Should there be much jaw spasm at the moment when it is desired to introduce the "air-way" it may be necessary to separate the teeth by means of a Mason's gag. It is advisable to secure a fairly deep anæsthesia before the instrument is placed *in situ*, otherwise inconvenient reflex retching and coughing may be excited. The appliance is, in fact, only suitable for cases in which it is desired to maintain a fairly deep anæsthesia. As regards the administration after the introduction of the "air-way," it must be remembered that with the more free intake of atmospheric air less anæsthetic will be required. In cases in which partial occlusion of the upper air-tract exists much of the vapour which is presented to the patient never actually gains access to the pulmonary passages. If, therefore, a certain rate of administration has been in force during the period of hampered breathing this rate must be reduced when the insertion of the "air-way" has secured free respiration, otherwise an unnecessarily deep anæsthesia will result. As the air-way does not project beyond the lips it may be used either during the administration of ether, chloroform, or chloroform mixtures. The writer finds it of great value when anæsthetising patients in the Trendelenburg posture, for in this posture the swollen tongue frequently obstructs breathing.

Messrs. Barth and Co. of 54, Poland-street, Oxford-street, London, W., are the makers of this artificial "air-way." I am indebted to them for having made other experimental appliances for me whilst working at this subject.

Queen Anne-street, W.

THE "EARLY" OPERATION IN ACUTE APPENDICITIS: THE INDICATIONS FOR ITS PERFORMANCE AND ITS ADVANTAGES.[1]

BY F. A. SOUTHAM, M.B. OXON., F.R.C.S. ENG.,
SURGEON TO THE MANCHESTER ROYAL INFIRMARY; PROFESSOR OF CLINICAL SURGERY, MANCHESTER UNIVERSITY.

THE advisability of early surgical interference in cases of acute appendicitis is becoming more and more recognised every day and instead of waiting for indications of suppuration, as was formerly the practice, we now attempt to forestall this complication by operating at a much earlier stage in the course of an attack.

For clinical purposes we may divide cases of acute appendicitis into two classes—viz., simple and destructive. In the first variety there is a simple or catarrhal inflammation of the mucous membrane which does not run on to suppuration or perforation but terminates in resolution, though often leaving the appendix in a somewhat altered or damaged condition with a tendency to recurrent attacks. In the destructive form serious changes result, either a localised perforation or more or less extensive gangrene of the walls of the appendix, both conditions being usually accompanied by suppuration. This may take the form of an encysted abscess or there may be a formation of pus either localised, i.e., at first confined to the region of the appendix, though not encysted or surrounded by a barrier of lymph, but soon spreading and becoming more or less general, i.e., diffused throughout the peritoneal cavity ("diffuse suppurative peritonitis"), if the case is allowed to run its course.

It has recently become the custom to divide the course of an attack into three stages—viz., (1) the "early" stage, which includes the first 48 hours; (2) the "intermediate" stage, which extends from the third to the fifth day; and (3) the "late" stage, which extends from the fifth day until the termination of the case. Operations are now classified as "*early*," "*intermediate*," and "*late*," according to the corresponding stage in which they are performed.

During the past year it has been my practice, when possible, to operate at a much earlier period than formerly, i.e., in the "early" stage, in all cases where the initial symptoms were of a grave nature and indicating that destructive changes were taking place, or were likely to do so, in the walls of the appendix. So far the results have been most satisfactory, and I append a brief record (Table I.) of ten cases, all operated upon in the "early" stage, viz., within 48 hours, the onset of abdominal pain or sickness being taken as the initial symptom. In each instance the appendix was removed at the same time and all the patients made a good recovery. These cases all occurred in private practice, it being unusual to obtain the opportunity of such early operation in hospital patients. That this is so is proved by a reference to Tables IV. and V., which include all the acute cases, 26 in number, admitted into my wards at the Manchester Royal Infirmary during the same period. Some of these were operated upon by myself, the others by the honorary assistant surgeons (Mr. J. W. Smith, Mr. A. H. Burgess, and Mr. J. H. Ray), or by the resident surgical officer (Mr. P. R. Wrigley). None of the 26 cases were admitted in the "early" stage and therefore operative interference was not possible within the first 48 hours. The contrast in the result is striking, for of the 26 hospital patients operated upon in the "intermediate" she displayed the symptoms described.—Professor CUSHNY replied.

---

[1] A paper read before the Manchester Medical Society on March 27th, 1907, in a discussion on the Diagnosis and Treatment of Acute Appendicitis.

Professor W. E. DIXON dealt with Arterio-Sclerosis and its Causation. He referred to two theories of causation—(*a*) raising of blood pressure and (*b*) toxic influences, and showed that it had been established conclusively by experiment that arterio-sclerosis could be produced in the lower animals by simply compressing the abdominal aorta for one minute once or twice a day for a comparatively short period. The changes consisted in a drawing out of the elastic fibres and degeneration of the muscular coat, plaques of calcareous material being formed. He explained how this might be brought about in man owing to violent exercise, and more especially was this likely to occur as man grew older, as the rise of blood pressure was then greater after exertion than in youth. Professor Dixon also spoke of the effect of nicotine on the blood pressure, comparing the sudden high rise in the young non-smoker after his first cigar with the slight rise in the moderate smoker and the absence of effect in the habitual smoker. He concluded by stating that man produced a ferment, probably in his liver, which counteracted the effect of nicotine.—Professor CUSHNY hoped that the study of this subject might lead to some advance in treatment. He did not think that the raising of blood pressure in man by the administration, for example, of digitalis would give rise to these changes.—Dr. SAVILL stated that he was surprised to hear that the compression of the abdominal aorta for such short periods in small animals should give rise to so serious changes in the aortic arch as had been described by Professor Dixon.—Mr. MABEN also spoke.

OTOLOGICAL SECTION.

Ménière's Disease.—Primary Epithelioma (?) of the Tympanum.—Exhibition of Cases and Specimens.

A MEETING of this section was held on Feb. 8th, Dr. PETER MCBRIDE, the President, being in the chair.

Mr. H. TILLEY showed a case of Extensive Development of Keloid in the Line of Incision made for Mastoid Operation. Various suggestions with regard to the occurrence of keloid were put forward by members of the section and also methods of treatment. Mr. Tilley proposed to try the x rays and, if not successful, to excise the scar freely.

Dr. D. R. PATERSON showed an unusual case of Cerebellar Abscess in a boy, aged 11 years, who had only been ill three weeks without any apparent sign of middle-ear suppuration. The chief symptoms were tenderness along the posterior border of the mastoid and optic neuritis. The abscess was opened by operation and the patient made an uneventful recovery without impairment of hearing.

Mr. SYDNEY R. SCOTT showed an interesting series of Histological Preparations of the Human Cochlea.

Mr. ARTHUR H. CHEATLE showed a specimen of the Right Temporal Bone of a Man in which, owing to the anatomical arrangement of the cells, it was possible for pus in the antrum to reach the neck without passing through the mastoid process.

Mr. RICHARD LAKE read the notes of a case of Ménière's Disease in a girl aged 14 years.—It was suggested by several members of the section that the cause of the symptoms might be due to congenital syphilis.

Mr. R. STURGEON COOKE showed a Case for Diagnosis—namely, a girl, aged eight years, in whose left mastoid region was situated a hard swelling of about half the size of a pigeon's egg, which had gradually increased in size since it was first noticed 15 months ago.—The members could not agree to a definite diagnosis, which was variously given as a calcified gland, a bony growth, an enchondroma, a solid dermoid, or a new growth. Mr. Cooke was asked to report the result found at operation at the next meeting of the section.

Mr. HUNTER F. TOD showed the following: 1. A case of Vertigo in a man in whom the coördination tests, as suggested by von Stein, demonstrated a definite lesion of the semicircular canals on the right side. 2. An unusually interesting case of Lateral Sinus Thrombosis occurring in a boy aged eight years. A few days after the operation there were facial paralysis on the opposite side, paresis of the sixth nerve on both sides, and optic neuritis on the affected side. For a considerable period the boy was very ill and showed definite signs of basal meningitis. Convalescence was slow and with this complete recovery of all the symptoms. Two months later optic atrophy was noticed on the left (the opposite) side which was now well marked; otherwise the boy was restored to complete health.

Mr. A. L. WHITEHEAD read notes of a case of Primary Epithelioma (?) of the Tympanum, following chronic suppurative otitis media. The first symptom of the disease was an aural polypus which was very vascular and which recurred on removal. Eventually the mastoid operation was performed and the growth was found to extend deeply into the cochlea and petrous bone and forwards involving the orifice of the Eustachian tube. The hæmorrhage during the operation was so profuse as to be almost alarming but was arrested by pressure. Eight weeks after the operation the wound cavity was dry and covered with epithelium. There had been no recurrence since the operation, performed 12 months ago. The pathologist's report stated that the growth had the structure of an atypical carcinoma. A microscopical section was referred to the Morbid Growths Committee for further examination.

Dr. J. BARRY BALL showed a case of a Pulsating Growth in the Left External Auditory Meatus in a man aged 73 years. The patient had consulted Dr. McBride ten years ago who noticed a small growth in the meatus. Since then it had increased slowly and occasionally there had been a sharp attack of hæmorrhage. The growth filled the meatus and protruded slightly from the orifice; there was a distinct expansile pulsation in it which was communicated to the auricle and the pre-auricular region. The growth was presumably angeiomatous in nature.—The question of tying the external carotid artery was discussed but the opinion of the section was that owing to the age of the patient and the duration of the growth it would be wiser to do nothing.

MEDICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on Feb. 10th, Dr. J. KINGSTON FOWLER, the President, being in the chair.

Dr. F. DE HAVILLAND HALL showed a case of Ascites treated by Epiplopexy. The patient, a man aged 35 years, was admitted into the Westminster Hospital on Nov. 7th, 1907, complaining of swelling of the abdomen. He gave a history of a chancre five years ago; four years ago he had right-sided pleurisy and was at home for eight weeks. He stated that he was a heavy drinker until about the age of 30; since then he had drunk on an average four or five pints of beer daily and occasionally spirits. About 12 months ago he noticed that he was getting thinner and since that time there had been gradual loss of flesh. Four months ago he noticed that he was getting fuller about the abdomen and the swelling had steadily increased up to the time of admission. On admission the patient was thin and sallow. The liver was palpable for about four fingers' breadth below the costal margin; the surface was hard and irregular. There was no jaundice. The abdomen was distended with free fluid. On Nov. 11th and 26th and Dec. 17th the patient was tapped and 9 pints 5 ounces, 10 pints 8 ounces, and 16 pints respectively were drawn off. On Jan. 7th Mr. W. G. Spencer made a vertical incision about two inches long three inches below the ensiform cartilage. The liver was examined and presented white lumps which were regarded as either of syphilitic or malignant origin, probably the former. Another incision was made in the median line below the umbilicus and a drainage-tube inserted; a portion of the great omentum was sutured to the upper wound. On the next day a large quantity of fluid escaped through the drainage-tube; the tube was removed five days later. Since the operation the patient had been treated with liquor hydrargyri perchloridi and iodide of potassium.—In answer to a question by the PRESIDENT, Mr. SPENCER said that patients who had been thus operated on showed enlargement of the superficial veins, sometimes to such an extent that a photograph could be taken of the veins.

Mr. W. H. BATTLE showed a case of Diffuse Cancellous Osteoma of the Femur following Fracture in a boy, aged three and a half years. He was admitted to the Rochester Hospital for a fracture of the right femur on July 11th, 1907. The fracture, which was situated slightly below the middle of the shaft, was caused by a fall from a fence. On August 1st it was noticed that there was an unusual amount of swelling of the thigh; on the 11th this had increased and extended the whole length of the shaft of the femur and measured 14 inches in circumference. On the 14th an examination of the growth was made under an anæsthetic and a piece was removed. This was examined and consisted

TABLE IV.—INTERMEDIATE OPERATIONS (*i.e., third to fifth day*). HOSPITAL CASES.

No.	Date of operation.	Sex.	Years of age.	Duration of symptoms.	Suppuration.	Removal of appendix.	Condition of appendix.	Result.

Number of cases, 12. Died, 1. Mortality, 8 per cent.

104° F. On the other hand, a subnormal temperature, especially if the fall has been sudden, often indicates that perforation has taken place, and the pulse-rate may not be increased under the same conditions. A high temperature and a slow pulse, or *vice versâ*, are always unfavourable symptoms. An initial rigor is always a grave symptom and should be regarded as a danger-signal. Urgent vomiting or acute pain at the onset renders it probable that the attack will be a severe one. Painful rigidity of the abdominal wall, especially if general, when well marked in the early stage, is always a most important indication of the gravity of the attack and generally symptomatic of the existence of acute peritonitis.

Another early symptom upon which I place great importance as indicative of the latter condition and pointing to the onset or the presence of the destructive form of appendicitis is the absence of abdominal respiration, the breathing being mainly or entirely thoracic. If the patient is told to take a deep inspiration, the abdomen being freely exposed to view, it will be found that there is either no movement whatever of the abdominal wall or only a very slight expansion at its upper part—viz., immediately below the sternum and lower margin of the ribs. Even this amount of movement is frequently absent and occasionally there may be noticed a slight in-drawing of the abdominal wall in this situation if the pain does not prevent the patient from taking a deep breath. When this state of the abdomen is present at the onset of the attack and there are in addition the three cardinal symptoms of appendicitis, viz., pain, tenderness, and rigidity of the abdominal wall, most marked over the region of the appendix, together with quickened pulse and increased temperature, or even without much alteration in pulse and temperature, it is probable that the attack is, or will be, of a severe character—i.e., of the destructive type. This motionless condition of the abdomen during respiration was observed in all the cases recorded in Table I. and it was the main indication which induced me to advise immediate operation even when there was little increase in the pulse-rate or temperature (as in Cases 1, 7, 9, and 10). I believe it is always indicative of the presence of peritonitis, and a reference to the cases in Table I. will show that in these circumstances serious changes were commencing, or had already taken place, in the walls of the appendix.

The advantages of surgical interference in the early stage of acute appendicitis are as follows: 1. The infective centre—i e., the appendix—can be removed in many cases before suppuration has taken place, and if it has not perforated or become gangrenous the operation is practically an aseptic one. 2 If pus has formed, even though not encysted and surrounded by a barrier of lymph, it will usually be found to be localised as yet to the neighbourhood of the appendix and small in quantity (Table I., Cases 1, 5, 8, and 10). In these circumstances its evacuation, together with the removal of the appendix, if followed by free drainage, will usually check the spread of the suppuration which otherwise so often tends to become general. 3. The operation being performed before the onset of general toxæmia, the common cause of death in fatal cases, is usually well borne by the patient. 4. The risks of the later complications of acute appendicitis, viz., subphrenic and hepatic abscess, empyema, parotitis, phlebitis, and infections in other parts of the body, are greatly minimised. In past years I have met with instances of all the secondary complications just mentioned. 5. In the early stage the appendix—unless bound down by adhesions the result of a previous attack—lies quite free and is therefore easily removeable. In the later stages, especially in the less acute cases, it is often surrounded and imbedded in a deposit of lymph, which may form part of the wall of an abscess when the pus is encysted. In these circumstances, it is often not easy to recognise the appendix, and its removal is frequently difficult or impossible without breaking down this barrier of lymph, and thus running the risk of infecting the general peritoneal cavity.

It is a question whether the rule of early operation in acute appendicitis might not with advantage be extended to all

Dr. EDMUND CAUTLEY read a paper on the Pathology of Congenital Hypertrophy of the Pylorus in Relation to Treatment. Accepting the view that there is such an affection as pyloric spasm and that the action of the pylorus is that of the closed door which only opens in response to duodenal stimuli, he argued that there was no evidence that spasm could cause hypertrophy. Almost all physicians had found antispasmodic drugs of no value in treating pyloric hypertrophy, a remarkable fact if the symptoms were due to spasm grafted on to, or causing, hypertrophy. Moreover, spasm might occur at any age, and yet these cases of hypertrophy were peculiar to the first few months of life, and there was no evidence of spasm at a later age causing hypertrophy. Recovery from pyloric spasm under medical treatment, in cases mistaken for true hypertrophy, had led to an unduly favourable estimate of the value of medical treatment in true hypertrophy. The latter affection varied from a degree of hyperplasia which was fatal unless treated surgically, down to a slight hyperplasia which was compatible with life, if no secondary effects occurred. These effects—viz., dilatation of the stomach, gastric catarrh, and occasionally acute œdema of the pyloric mucosa—were due to contraction of the muscle. In mild cases the degree of contraction might prevent sufficient nutritive food passing through the pylorus and yet not set up the secondary symptoms. Three of his cases had been of this type and under medical treatment had succumbed to marasmus, although food was present in the intestines after death. It was these cases in particular that made a person critical of the assumed value of diet and lavage. Drugs he had found useless. A diet of whey or albumin water, carefully regulated, would suit such cases for a time but as soon as the strength of the food was increased the secondary symptoms arose. On the assumption that the condition was induced by hyperchlorhydria cases had been treated by undiluted cow's milk. Such a food had proved useless in his hands and he suspected that the successful cases were due to pyloric spasm. Recent observations by Miller and Willcox supported the view that there is no excess of acid in these cases and all clinical and pathological evidence was in favour of the weak nutritive fluid rather than undiluted milk. Lavage would be useful in hyperchlorhydria and pyloric spasm but could hardly be expected to be of value in cases of mild hypertrophy without secondary symptoms. It seemed unnecessary if food was passing through the pylorus, if vomiting was absent, and if there was little or no dilatation. There were undoubted cases of this type. It was of great value in curing secondary dilatation and gastritis, but it only cured these secondary effects and not the hypertrophy and might place the child in the *status quo ante*. Then if the degree of hypertrophy and contraction was compatible with life the child might recover. He regarded it as of vital importance to differentiate spasm from hypertrophy and thought that the medical treatment of true hypertrophy should not be unduly prolonged. The greater the degree of marasmus previously to operation the smaller was the chance of the child's recovery.

Dr. G. A. SUTHERLAND protested against the assumption that if pyloric stenosis were cured medically it must have been in such a mild form that it would have recovered without treatment. Operation was a very serious matter and many infants who had stood the operation died afterwards from bowel trouble of some sort. He did not think that for a complete diagnosis one should be able to feel a pyloric tumour, as the pylorus was a very uncertain thing to feel in an infant. The diagnosis could be made if vomiting, constipation, wasting, and marked visible peristalsis were present. Where trouble arose when breast milk was given the fault was not with the milk but with the manner of feeding. Small feeds of the most digestible materials were required and if there was a residue of food left in the stomach after washing out for a day or two the infant was not having suitable food.

Mr. J. P. LOCKHART MUMMERY said that it was scarcely possible to have a more unsuitable subject for a severe operation. The child was very young and badly nourished and had probably been vomiting all the nourishment given for some days before. Very few cases died on the table. The only patients in whom the prospect of operation was good were those seen early before there had been wasting and in whom there was a fair amount of fat.

Dr. CHARLES W. CHAPMAN said that in the condition under discussion there was a great deal of irritation causing the closure and he was therefore surprised that no one had suggested the administration of carbonate of bismuth. It might be given freely in as much as teaspoonful doses.

Mr. HUGH LETT said that the members were much indebted to the readers of the papers as the subject was one of great importance. Surgical treatment was a very serious matter and in many cases by the time the surgeon was called in the condition was practically hopeless. The physician should be clear at the beginning of his treatment how long he would continue medical measures, lest by unduly prolonging them the prospects of operation were affected. He advocated the claims of gastro-enterostomy as being simpler than pyloroplasty and safer than Loreta's operation.

Dr. REGINALD H. MILLER suggested that the symptoms of pyloric stenosis were entirely referable to spasm. First, because of the onset of the disease. At the Clinical Society of London last year 40 cases were collected and in 70 per cent. of them the onset did not occur until the third or fourth week of life. He had a case in which diarrhœa preceded the onset of the symptoms. It was true that many babies vomited from birth but not sufficiently to cause wasting, and the well-marked constipation was frequently absent during the first two or three weeks of life. That suggested that there was not marked blocking at the pylorus as a congenital lesion. Again, even though the baby were not saved by lavage and careful dieting, he or she usually died from diarrhœa, showing that the pylorus was once again patent and that something had happened, for presumably the spasm had been relaxed. Such cases strongly simulated the real condition which Dr. Cautley referred to, and he (Dr. Miller) thought that they were quite identical. It was difficult to say what was the cause of the spasm, but he thought that it was due to a congenital defect in the gastric juice, and he had tried to find what that defect was in the observations alluded to by Dr. Cautley; he believed the so-called hyperacidity was not the cause. It would be a very engaging idea if it were so. Hyperacidity was found in babies who ran a different course, generally getting well in a few weeks. The hyperacidity of pyloric spasm occurred in older and less wasted children, the tongue was clean, and there was no true peristalsis so that the viscus stood up on palpation. There was Mr. Clinton T. Dent's well-known fœtus in which the pylorus was found hypertrophied. He regarded spasm of the pylorus as the entire cause of the symptoms of the condition, if not of the disease itself.

Dr. T. R. WHIPHAM showed a case of Congenital Heart Disease in a girl, aged 17 years, who showed no cyanosis or clubbing.

Dr. J. PORTER PARKINSON showed a case of Synovitis of the Knee-joint without pain or tenderness in a boy, aged seven years. The patient was the subject of congenital syphilis and the effusion followed periostitis of both tibiæ.

Dr. SUTHERLAND showed: 1. A case of Cretinism. The patient, a boy, aged nine years, was seen in November, 1907, when typical signs of cretinism were present. He improved markedly under thyroid treatment. Growth in the long bones was very delayed and pituitary extract had been given without any benefit so far. 2. A case of Tuberculous Peritonitis in a girl nine years old. When first seen in September, 1907, the case seemed hopeless. There had been signs of tuberculous peritonitis for five months. The patient, who was wasted and in a stuporous condition, suffered from diarrhœa and had delirium at night and hallucinations during the day. She was now convalescent and the signs of active tuberculosis had subsided, although the abdomen was still distended.

Dr. MCMASTER (for Dr. L. G. GUTHRIE) showed a case of Acute Polioencephalitis following Measles. The patient, a girl, aged five years, was well nourished and intelligent but had spastic diplegia. There were no ocular symptoms. There was weakness of the muscles of the back so that she could not sit upright and could not hold her head up. The condition simulated one of congenital spastic diplegia.

Mr. LOCKHART MUMMERY showed a case of Supernumerary Auricles in an infant, on both sides of the head, situated just in front of the external auditory meatus in the position of the inter-maxillary cleft.

LIVERPOOL MEDICAL INSTITUTION.

The Physics of the Mitral Regurgitant Murmur.

A MEETING of this society was held on Jan. 16th, Mr. THOMAS H. BICKERTON, the President, being in the chair.

Dr. T. R. BRADSHAW read a paper on the Physics of the Mitral Regurgitant Murmur, especially with regard to its audibility at the heart's apex. He assumed the correctness of

I have not what one might call an extensive personal experience of plague, as most of my cases are sent into the lazaretto here and then I lose sight of them, but I should like to report the effect of Yersin's serum in the few cases of foreigners that I have treated myself as I feel sure that this serum is maligned.

CASE 1.—The patient was a woman, aged 22 years. I was called to see her about 4 P.M. Her temperature was 103° F. Her face was flushed and she was feeling very ill. I visited her at 8 A.M. on the following day when her temperature was 105°. I called in the medical officer of health who confirmed my opinion that it was a case of bubonic plague. At 12 noon we gave an intravenous injection of Yersin's serum, the dose being 80 cubic centimetres. About two hours later the patient had a rigor. On the day after there was no fever and she was feeling much better. In this case the patient completely recovered except that she suffered from rheumatism about 14 days later, the effects of the injection.

CASE 2.—The patient, a man, aged 50 years, was admitted to hospital as a case of typhoid fever (?). His temperature was 102° F., the pulse was dicrotic, and the spleen was palpable. Two days later a bubo appeared in the left groin. The patient was given 40 cubic centimetres of serum intravenously with the effect that the temperature fell to normal, but he had no rigor. Two days afterwards the temperature again rose to 102°; the same dose was repeated and the temperature fell to 100°. The man died, however, in a comatose condition, and I believe that in this case I gave insufficient serum but was advised not to increase the doses.

CASE 3.—The patient, a man, aged 25 years, was seen at 12 noon. His temperature was 106° F. in the rectum. He had been quite well the day before. I called in the medical officer of health who agreed that the man was suffering from bubonic plague. The patient was given an intravenous injection of 80 cubic centimetres of serum. His temperature on the next morning was normal. On the following day the temperature in the rectum was 104°. The dose was repeated and the temperature fell to 100° and kept so for two days, when he began to cough and to expectorate pneumonic sputum. This was examined microscopically and was found to contain numbers of bubonic bacilli. On examination the right apex was found to be consolidated. I then thought the case almost hopeless and gave the patient an intravenous injection of 130 cubic centimetres of Yersin's serum. Two hours later he had a *severe* rigor. The temperature on the following day was normal, there were much less cough and sputum, and the lung was better. After this the patient made an uninterrupted recovery except that about ten days later he had rheumatism and fever, no doubt due to the injections.

These are the three cases that I myself have attended and they seem to me to show that: (1) unless the patient has a rigor after the injections they have not had a large enough dose; (2) that the doses advised are not nearly large enough for severe cases; and (3) that there is no ill effect from large intravenous injections of Yersin's serum.

I am unaware what dosage is generally used in India, but I presume from about 20 to 40 cubic centimetres as per instructions. At the same time I am aware that three cases are insufficient to judge from, but I was anxious to give only those that I myself could vouch for, although I could get plenty more examples of large doses from the Chilian lazaretto in this town with excellent results.

Antofagasta, Chili.

NOTE ON A CASE OF SEPTICÆMIA DUE TO PNEUMOCOCCUS; DEATH.

By JOHN BELL, L.R.C.P. LOND., M.R.C.S. ENG.,

SUPERINTENDENT OF THE GOVERNMENT CIVIL HOSPITAL, HONG-KONG.

AN Indian male, aged 22 years, was admitted to hospital under my care on Dec. 1st last, with a fluctuating swelling just below the left clavicle which he attributed to having tried to raise a very heavy box a few days previously. The abscess, containing about two ounces of pus, was opened on the next day and the case progressed well up to the 12th when there was still a small sinus about one inch in depth. The patient was most anxious to leave the hospital but he was kept in until the wound was completely closed. On the next day he complained of feeling chilly with pains all over and there were a few fine crepitations at the base of the right lung. His temperature in the morning was 99° F. and in the evening it was 100°. On the 14th he felt better, the temperature in the morning being 98·4° and in the evening 100·8°. On the 15th he was very seriously ill. He had much pain and discomfort all over the abdomen, especially over the bladder, where there was a diffuse swelling extending to the flanks. There was slight delirium, the tongue was very dry and furred, and there were hæmorrhages under the conjunctivæ and petechial eruption all over the body. The temperature was 100·6° and the pulse was very small and quick. The wound looked well. A blood slide showed no plague bacilli or malarial parasites, but was full of normoblasts. The patient was not anæmic. He rapidly succumbed and died in the afternoon.

Post mortem, the abdominal swelling consisted of a large extravasation of blood between the skin and the peritoneum through all the muscular layers and extending on both sides to the back to the level of the pelvic brim. Smears from this were full of typical pneumococci. The heart was covered with small petechiæ, and the blood from the ventricle showed almost a pure growth of capsulated pneumococci. All the other organs were healthy and the wound was normal, though a scraping from the sinus also showed pneumococci. Dr. C. M. Heanley, Government bacteriologist, who was present at the time, kindly saw the slides and agreed with the diagnosis of septicæmia due to pneumococcus.

The patient was a healthy, well-nourished Indian and the abscess was quite superficial and was treated throughout aseptically. It is difficult to understand why, when he was practically well, such a serious disease should arise which carried him off in 48 hours.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION.

Nutmeg Poisoning.—Arterio-sclerosis and its Causation.

A MEETING of this section was held at the Apothecaries' Hall, Blackfriars, on Jan. 28th, Dr. T. E. BURTON BROWN, the President, being in the chair.

Professor A. R. CUSHNY gave an address on Nutmeg Poisoning. He referred to the scanty recognition of this in English medical literature and noted the work of his former assistant, Dr. Wallace, in America, who found that cases of poisoning occurred exclusively from the use of the crude nutmeg or mace; in many instances it had been used as an abortifacient, although it does not appear to have this action. As far back as 1576 Lobelius relates a case in which a woman was rendered delirious by nutmeg. The symptoms are drowsiness, stupor, diplopia; delirium frequently is present, and sometimes the first symptom is burning pain in the stomach, præcordial anxiety, or giddiness. One case of death in a boy occurred after eating two nutmegs. The symptoms resembled those caused by cannabis indica. Professor Cushny showed how the powerful poison was contained in the oil of nutmeg and it was the fraction which came over at 150° C. under 14 millimetres mercury pressure; from this several bodies have been isolated—e.g., myristicin. From experimental work Professor Cushny came to the conclusion that the symptoms were to be attributed to the action on the central nervous system, which was depressed but exhibited some indications of stimulation in the form of restlessness, slight convulsive movements, and tremor. The oil also had a marked local irritant action, whether given by the mouth or hypodermically. The stomach wall was found red and injected, the urine often containing albumin.—Dr. POWER (introduced by Professor Cushny) said that he had been working on the chemistry of oil of nutmeg, which he found a very complex mixture. He had isolated large quantities of myristicin which did not conform in its features with the substance described by Semmler under that name. He drew attention to the very small amount of myristicin contained in the quantity of nutmeg necessary to induce poisoning, this suggesting a doubt to his mind whether the symptoms were entirely due to this body.—Dr. J. GRAY DUNCANSON mentioned the case of a woman who aborted after taking, amongst other things, a ground nutmeg in gin;

of the bowel, and peritonitis was present. An end-to-end anastomosis of the resected gut was performed but the patient only lived 36 hours after the operation.

Mr. F. T. PAUL and Mr. FRANK A. G. JEANS showed: 1. Hydatid Cyst of Retrorenal Tissue. The kidney, which was stretched over the cyst, was removed with it. There were no urinary symptoms. 2. A Chronic Ileo-colic Intussusception from a man, aged 23 years. The operation involved removal of the ileum, cæcum, the ascending, and half the transverse, colon. 3. A Carcinoma of the Transverse Colon. An immediate end-to-end anastomosis had been attempted with fatal result.

Dr. R. J. M. BUCHANAN showed specimens of Myelocytes from a case of Myelogenous Leukæmia. The cells had been washed twice with sodium citrate solution and once with normal saline solution in the centrifuge. On staining the films with Leishmann's stain the myelocytes showed long flagella projecting from the surface and were more granular, the granules responding to the stain in the same manner as the nuclei. In some of the flagella a few granules could be seen, while into others strands of nuclear chromatin extended. These flagella did not resemble pseudopodia and the cells in which they occurred were slightly if at all amœboid.

Professor A. M. PATERSON exhibited Specimens and Models illustrating the Normal Form of the Stomach, and variations from the normal type, including several examples of "hour-glass" stomach resulting from hypertrophy of the circular muscular coat of the organ between the cardiac and pyloric portions.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

The Treatment of Gastric Ulcer.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Jan. 31st, Dr. J. ALLAN, the President, being in the chair.

Dr. A. G. BARRS and Mr. B. G. A. MOYNIHAN opened a discussion on the Treatment of Gastric Ulcer.

Dr. BARRS said that the rapid rise and striking success of the surgical treatment of gastric ulcer had invested the subject with a new interest and a greater importance, whilst the responsibility of the physician had proportionately increased, for with him still rested, and very properly so, the duty of determining in any given case whether medical or surgical treatment should be adopted, and it was only by maintaining him in his position of judge of first instance that unnecessary, and therefore unjustifiable, operations were to be avoided. The first and by far the most important question the physician had to decide in the treatment of any case of gastric ulcer was whether the case was one for medical treatment at all. He said that was a question to which he had up to a *certain point no difficulty* in making an answer which he thought would be generally accepted. The following cases, he thought, should be handed over to the surgeon without delay: (1) all perforations or suspected perforations; (2) all cases in which visible and palpable signs were present, due either to perigastritis or dilatation; (3) probably all male cases; (4) many of the older female cases, in which gastric ulcer was rarely got rid of without operation and in which duodenal ulcer was not infrequently present; and (5) all cases which, though having no visible or palpable signs, resist prolonged and efficient medical treatment, especially those with repeated hæmatemesis, even though the hæmatemesis was small in quantity. Where no definite lesion in the stomach was detected when the abdomen was opened he would suggest that no gastro-enterostomy should be done. No cases of first hæmatemesis should be treated by operation and he thought that in no case of repeated hæmatemesis should an operation be performed during the actual bleeding. He said this because the surgeon's present method of dealing with hæmatemesis was not scientific. He (the surgeon) could not help it but it was usually impossible for him to deal directly with the bleeding point. When all these had been disposed of the physician was left with a large class of cases, represented most commonly by the young unmarried woman, frequently a domestic servant but rarely a *cook*, whose complaint was of months, or possibly years, of great suffering (frequently with striking intermissions) from severe gastric pains which were usually, but not always, aggravated by food and relieved by vomiting, with or without occasional and profuse hæmatemesis along with profound anæmia and cachexia. These young women were, as a rule, poor meat-eaters by nature, and many of them had had their teeth destroyed by the medicinal use of iron. Of physical signs in the abdomen in these cases there were none save superficial sensitiveness in Head's gastric area and tenderness on pressure in the epigastrium. The area of tenderness was, as a rule, quite definite and easily covered by the end of a thumb. This was the type of case which it was customary to treat by medical means and apparently with much success. Almost all of these patients were entered as "cured" when they left the hospital. But gastric ulcer was a very inveterate and long-drawn-out disorder, and many of the so-called "cures" were, he was afraid, very temporary affairs. Patients returned again and again, especially the older ones, until, as a last resort, gastro-enterostomy had to be done; so that in regard to these cases he would say that medical treatment should always be tried for a reasonably long period of time; but if frequent relapses occurred and above all if frequent hæmorrhages—large or small—occurred gastro-enterostomy should be done. But his experience of the surgical treatment of the intractable cases of this class, without definite physical signs, had not been *without its* disappointments, for it was obvious that the more definitely mechanical the causes of the symptoms were the more certainly were they relieved by the purely mechanical procedures of the surgeon; that was to say, surgery was most successful in cases where the ulcer had produced mechanical defects in the stomach. What then should be regarded as efficient medical treatment? The most essential part of medical treatment was prolonged and complete rest in bed; without that all other means were of no avail whatever. To make a diagnosis of gastric ulcer, whether it turned out to be right or wrong, and, at the same time, to allow the patient to be out of bed, was, to his mind, an unpardonable *inconsistency*. The moment a patient was even suspected of gastric ulcer she should be put to bed. He was not permitted to enter into the question of diagnosis but he would like to say that they ought *not* to insist upon *the presence* of hæmatemesis or even of vomiting before making a working diagnosis of gastric ulcer. Having put the patient to bed what next was to be done? The general public, and possibly *many of the profession*, still thought that diet was the most important thing in the treatment of gastric disorders. As time went on his system of dietetics became simpler and simpler, and he thought that any adult patient (except perhaps a diabetic subject) who could not take ordinary articles of diet—that *is, solid food*—had better take no food at all and lie in bed and drink water until he could. He never ordered milk for patients with gastric ulcer; he repudiated entirely the old practice of saying to a patient with gastric ulcer, "A milk diet or your life." He wished they could see the *same reduction* in the milk bills of the hospitals as recent years had seen in their alcohol bills. He could not *understand how* they as a profession could go on countenancing milk drinking in bulk by adult patients and the public at large, *knowing* as they did that it was probably the surest way of introducing the tubercle bacillus as well as other pathogenic organisms into their bodies. Bulk was a much more important consideration in the food of a patient suffering from gastric ulcer than *kind*, and small meals of meat and stale bread (if they could be taken *without pain and not unless*), along with water in any *reasonable quantity* to drink, was the food which he usually suggested, but if there were vomiting no food should be given, *only* plain fresh water to drink. He never used nutrient enemata or nutrient suppositories, but if vomiting prevented the taking of water *by the mouth* normal saline injections or injections of a solution of glucose should be employed. Enemata of any kind were not infrequently very distressing to patients and might induce vomiting. No patient with gastric ulcer *should* be allowed to leave her bed until she had taken ordinary mixed solid food at the ordinary meal times for ten days *at least*, ten days of food not only without pain but with enjoyment. He never ordered any *form of* artificial or artificially *digested* food for anybody, or any of the so-called digestives. For medicine he had great faith in bismuth carbonate in large doses given in plain water and not in the gummy mixtures which were at one time in vogue. *It should* be given 20 minutes before food was taken into the stomach. If there was very much pain a little morphine—say five or ten minims of the solution of morphine—could be given along with the at one end of well-formed bone, at the other of young connective tissue, and in the middle showed newly formed cartilage in process of ossification. The swelling continued to grow until the beginning of December when it measured 19 inches; since that time there had been diminution in size. The patient had made no complaint of pain. The tumour was a large fusiform swelling of the right thigh which tapered off below but had a more marked ending above. The bone was completely surrounded but the tumour was less marked posteriorly. It was of stony hardness and of even surface throughout. The thigh measured 14¾ inches at its greatest circumference, the left limb only measuring 7¾ inches. There was slight apparent lengthening. The boy was rather thin but not unhealthy-looking and presented no signs of tumour elsewhere. In the Transactions of the Society, Vol. XXV., p. 327 (1902), there was a reproduction of a photograph of a similar tumour which developed in an older brother, also as a result of fracture of the femur (left). The thigh was amputated at the hip-joint. Rapid recovery followed. In 1903 he had a tumour of the right femur, of the size of an orange and of the same structure as the original growth, as shown by the x rays. In 1907 the femoral tumour had disappeared, but he had a similar tumour of the right tibia. The original growth was found to be of pure bone without sarcomatous elements.

Dr. C. E. **BEEVOR** showed a case of Prolonged Ataxy after Diphtheria. The patient was a boy, aged 15 years, who on April 10th last was detained at a Metropolitan Asylums Board hospital for four weeks suffering from diphtheria. In the third week of illness the patient had occasional difficulty in swallowing and fluids regurgitated through the nose. This lasted for one week. On leaving the hospital he was very weak in the legs. He had diplopia for a day or two after leaving the hospital. He had had some dyspnœa and palpitation on exertion. There was some "incoördination" in the arms. In the upper extremities there were relative anæsthesia to cotton-wool and relative analgesia to pin-prick extending from the fingers to the elbows and shading off on passing up the limb. In the lower extremities there was stocking type of relative anæsthesia and analgesia. The "joint sense" and muscle pain sense were impaired. The upper extremity tendon-jerks were absent. The knee-jerks and ankle-jerks were absent. The gait was ataxic, the line of progression deviating equally to right and left. The gait was stumbling; the feet were lifted rather high and brought down flat with considerable force. He was unable to stand with the eyes closed when the feet were together. The case was very unusual for the length of time (ten months) from the attack of diphtheria that the symptoms had lasted, and such cases were rare. At the present time there was no definite paralysis but marked ataxy.

Mr. C. **GORDON WATSON** showed a patient, aged 11 years, who had been operated on for Perforation in Enteric Fever. The patient was admitted on Feb. 19th, 1907, to the Metropolitan Hospital on the fifth day of the disease under the care of Dr. Cautley. Perforation took place on the twenty-sixth day of the disease at 2.10 P.M. Laparotomy was performed within an hour. There were free gas and intestinal contents in the peritoneal cavity. The perforation was about 18 inches from the ileo-cæcal valve; it was closed and a second ulcer on the point of perforating was sutured over. The operation was completed in 21 minutes. Marked general improvement followed the operation.—Dr. **BERTRAND DAWSON** deprecated too far-reaching conclusions being drawn from one case. In the event of perforation taking place it had to be considered that the patient might get well without operation.—Dr. F. J. **POYNTON** described a case of enteric fever in which the abdomen was opened where no perforation had occurred but the abdomen was full of fluid swarming with typhoid bacilli.—Dr. E. **CAUTLEY** said that the advisability of operating for perforation in enteric fever must depend in each instance on the particular circumstances of any given case.

Dr. W. **ESSEX WYNTER** showed a case of Partial Obstruction of the Superior Vena Cava in a man, aged 43 years. There were cyanosis and venous engorgement of the head and arms, with well-marked clubbing of the fingers, and the liver was enlarged. There was no recognisable affection of the lungs or heart and the urine was normal. A loss of weight of 7 pounds was made good during a month's stay in hospital. The condition appeared to be referable to partial obstruction of the superior vena cava, either by thrombosis or some dilatation of the first part of the aortic arch, though the local signs were not obvious. Polycythæmia had been considered but it was hardly supported by the blood count.

Mr. H. J. **WARING** showed a case of Traumatic Myositis Ossificans. The patient, a boy, aged 17 years, was admitted to St. Bartholomew's Hospital on account of backward dislocation of both bones of the right forearm. The dislocation was reduced and an internal angular splint applied. Subsequently there was considerable limitation of movement at the right elbow-joint and a distinct hard swelling was discovered in the right antecubital fossa, on the deep aspect of the biceps and brachialis anticus, the brachial artery being pushed to the inner side. On operation this was removed from the deep aspect of the brachialis anticus and was not found attached to the bone.—The case was discussed by Dr. **CAUTLEY**, Mr. F. C. **WALLIS**, and Mr. **WATSON** who referred to the 87 cases of osseous formations in and about muscles due to injury described by Mr. Robert Jones and Mr. David J. Morgan.

Mr. **WALLIS** showed a case of Tumour treated by X Rays. The patient, a woman, aged 39 years, was admitted to Charing Cross Hospital suffering from respiratory obstruction due to pressure on the trachea caused by a growth. The growth was first noticed six months previously to admission and she felt some pain at the root of the neck and there was also some swelling. This increased until she had some difficulty in breathing. She also had great difficulty in swallowing and was losing flesh. When admitted her breathing was difficult and distressing. She sat up in bed, leaning well forward and having an anxious expression. There was a large swelling above the mediastinum, making the chest and throat one continuous line. There was another swelling in the left supraclavicular fossa and the trachea was pushed over to the right side for nearly one and a half inches. The cephalic vein in the left arm was very prominent and the glands in both axillæ were large, moveable, and hard. Percussion showed that the growth extended into the anterior mediastinum as far as the second intercostal space and the breath sounds in both lungs were generally deficient. The movements of the vocal cords were normal. The patient commenced x ray treatment on Jan. 15th and this was continued daily for over 14 days. Since Feb. 1st she had had three exposures a week with marked beneficial results which became obvious after the first week and a steady improvement had continued ever since, so that the woman could now breathe easily in the semi-prone position and could lie on her side. She slept well and could swallow and the growth was rapidly disappearing. A blood count showed that the patient was not suffering from splenic leukæmia and the growth in the opinion of Mr. Wallis was a lymphosarcoma. The growth had not been examined microscopically.—Dr. J. H. **DRYSDALE** related a case of sarcoma that improved under x ray treatment but eventually resulted fatally. He thought that the tumour described by Mr. Wallis might be a lymphadenoma.—Dr. R. C. B. **WALL** discussed the case from the point of view of Hodgkin's disease, and after Dr. W. H. **WILLCOX** had suggested that the tuberculin reaction might have been tried Mr. **WALLIS** replied.

Mr. **WALLIS** also showed a case of Ununited Fracture of the Femur with a Hoefftoke's splint applied.

Dr. **ROBERT HUTCHISON** showed a case of Splenomegalic Polycythæmia and Dr. **WILLCOX** a boy with Symmetrical Polyarthritis of the Hands.

Dr. **WALL** showed a case of Syphilitic Infiltration of the Superior Mediastinum.

Dr. **MORGAN DOCKRELL** showed three cases of Ulerythema.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

Congenital Hypertrophic Stenosis of the Pylorus.—Exhibition of Cases.

A MEETING of this society was held on Jan. 17th, Mr. **SYDNEY STEPHENSON** being in the chair.

Dr. **GEORGE CARPENTER** read notes of a case of Congenital Hypertrophic Stenosis of the Pylorus which he had treated in conjunction with Dr. D. J. Munro of Brixton and which had recovered under medical treatment, dieting, lavage, and drugs being the methods employed. He described the course of the case fully and then discussed the pathology and treatment of the condition. He considered that hypertrophic stenosis of the pylorus was a congenital abnormality of development and not a secondary muscular spasm, and maintained that similar cases should receive more thorough medical and dietetic treatment and that surgical intervention should not be invoked in the early stages. We hope to publish Dr. Carpenter's paper in full in a future issue.

eight to ten layers of the lint cut a very little larger than the size of the ulcer should be soaked in a 5 per cent. solution of zinc sulphate. The positive electrode (of zinc) must be connected with this and the negative pole to a basin of salt water into which the patient's hand is placed. The current must be gradually raised to from 40 to 60 milliampères or as much as the patient can bear conveniently and continued for 30 minutes. At the end of this time the surface of the ulcer would be whitened and dry. Another application might be made in a week or a fortnight. Many cases had been successfully treated by Dr. Turner in this way. Chronic ulcers were also amenable to the zinc ion. In fibrous ankylosis and sclerosis the chlorine ion or hydroxyl OH would be found of service. A case of Dupuytren's contraction of the fingers of 15 years' duration which had yielded to this treatment was shown. Even sclerosis of the spinal cord could be attacked and cases of spastic paralysis which had been treated by Dr. Turner in this way had benefited remarkably. A case of tic douloureux which had proved refractory to other remedies yielded to the electrolytic introduction of the salicylic ion.—Dr. A. D. Webster and Dr. Hunter took part in the discussion.

Mr. Albert E. Morison read a paper on 100 Consecutive Cases of Empyema. As regards the physics of pleural effusions he said: 1. That the intrapleural pressure was positive in purulent effusions, while in normal conditions the pressure was negative. 2. That an effusion into the pleural cavity first showed itself as an area of dulness (*a*) just below the angle of the scapula, (*b*) in the left axilla between the fifth and eighth ribs, (*c*) in obliteration of Traube's semilunar tympanitic space, and (*d*) in the right front near the angle made by the cardiac and hepatic lines of dulness. 3. That a disappearing effusion was last manifest in the axillary line between the fifth and eighth ribs. 4. That the root of the lung was its fixed point, and that with increasing effusion the lung became compressed round it. 5. That the re-expanding lung last touched the chest wall at a point diagonally farthest from its fixed point—i.e., in the axilla about the fifth interspace. This was the point of election for incision and drainage in cases of general purulent effusion and was the site of natural evacuation in cases of empyema necessitatis. 6. The lung did not tend to collapse on its fixed point when air was admitted into the pleural cavity, the intrapulmonary pressure being quite sufficient to maintain the two layers of pleura in contact, except for a small area round the point of entrance of the air. As regards the causes of empyema he said that: 1. Pleuro-pneumonia caused 91 per cent. of his cases. 2. Pleuritis was the cause in 4 per cent. It was generally agreed that if pleural effusions became purulent septic infection through dirty needles was almost invariably the cause. 3. Tubercle of the lungs was the cause in 3 per cent. and empyema followed a pneumothorax. 4. Septic disease of the abdominal organs accounted for only one case. 5. Streptococcic or staphylococcic infection of the lung. One case, due to osteomyelitis of the ribs, had occurred in his practice. Mr. Morison discussed at length the diagnosis of empyema and then considered the prognosis. This, he said, was as a rule good so far as life was concerned, the mortality in his series of cases being only 3 per cent. Natural cure might take place by: 1. Absorption of pus; this occurred in one case in which the parents of a child refused operation, the case being verified by puncture. 2. Spontaneous evacuation through a bronchus resulted in the cure of two cases, while in ten cases large quantities of pus had been expectorated prior to operation. 3. Discharge of pus into organs adjacent to the pleura (œsophagus and stomach). This could only occur where the accumulation was large and the disease prolonged. 4. Spontaneous evacuation through the chest wall (empyema necessitatis) occurred in five cases, subsequent operation being required. This was the most unsatisfactory of all forms of spontaneous evacuation. It usually occurred through or above the fifth interspace and œdema of the chest wall was a common signal. Recovery might follow in a few cases but the majority died from exhaustion or waxy disease. Four of these cases were cured by Estlander's operation, and the fifth by ordinary incision and drainage. 5. Surgical treatment offered the best results both immediate and remote. Mr. Morison's cases proved that uncomplicated empyema treated with proper surgical care was not a serious disease. Death in his three fatal cases was due to bronchitis, marasmus, and cerebro-spinal meningitis respectively. The perfect recovery of those operated on was also most satisfactory and months afterwards when examined, except for the scar, it was impossible to say which side had been affected. The average duration of treatment from the date of incision to the completion of healing was 32 days. In the treatment aspiration was only of service where the dyspnœa was great or where some complication rendered operative interference inadvisable. Whenever these were overcome operation should be performed. As regards operation it was advisable to administer a general anæsthetic to children while adults might be operated on with much greater safety under the influence of local anæsthesia. Chloroform was the best anæsthetic but the patient must never be moved from the dorsal position. The position of the pus should first be located by the needle and the site of incision which Mr. Morison usually selected was in the sixth interspace just in front of the posterior axillary line. A vertical incision was made through the skin and a horizontal one through the muscles along the upper border of the seventh rib into the pleural cavity; sinus forceps were then introduced and the wound was dilated by withdrawing them open. An indiarubber tube a quarter of an inch in diameter and two inches long was introduced and prevented from slipping in by a safety-pin being passed through its free extremity. As soon as the discharge became small the tube was cut in half. The wound was dressed with corrosive sublimate wool and changed twice or thrice during the first day and subsequently once daily, and later every second day. Resection of the rib was needful in some cases but generally was meddlesome surgery. As helping the expansion of the lung the patient was encouraged, as soon as out of bed, to make inspiratory efforts (running upstairs, playing wind instruments, &c.). The conclusions to be drawn were that (1) pleuro-pneumonia was the most frequent cause of empyema; (2) that empyema rarely followed pleurisy with effusion; (3) that in adults empyema was more likely than in children to be secondary to serious lung disease; (4) that the diagnosis of empyema was not always easy; (5) that the exploring needle should be used in all doubtful cases and in more than one situation; (6) that there was no danger in using the needle with proper care; (7) that the immediate prognosis in uncomplicated empyema by incision and drainage was good; (8) that the remote prognosis was excellent, no deformity following and no sequelæ resulting; (9) that careful asepsis must be carried out; and (10) that resection of the rib was needful in some neglected cases but generally was meddlesome surgery.—Dr. J. O. Affleck expressed his approval in the main of Mr. Morison's contentions.—Dr. W. Russell said that he was glad Mr. Morison did not remove a portion of rib in operating and yet got such good results. Mr. Morison had not referred to one special means of investigating difficult cases following pneumonia—namely, the leucocyte count. When a pneumonia was succeeded by empyema there was a great bound upwards in the number of leucocytes; in his last case there was a sudden rise from 25,000 to 40,000 or 45,000. It was not always easy to be satisfied that there was *not* pus in the pleural cavity. Dr. Russell did not think that bronchial breathing was ever heard over fluid, but it was present over compressed lung immediately above fluid. As regards acute fœtid empyema, he did not think that it was necessarily secondary to an abdominal lesion. The majority of acute fœtid empyemata occurred on the left side and commenced as cases of diaphragmatic pleurisy and owed their fœtor to the proximity of the colon on the *left side*.—Mr. Caird said that in the case of children it was obviously wise to use a general anæsthetic and it was rarely necessary to excise a portion of rib in such patients. In the case of adults it was better to employ a local anæsthetic and to remove a portion of rib.—Dr. Alexander James said that physical signs were of little importance if the empyema were small and localised, but he advocated the use of the exploring needle frequently. He thought that a great many cases of empyema discharged through a bronchus and cured themselves naturally.—Dr. Alexander Goodall and Dr. Hunter took part in the discussion.—In his reply Mr. Morison said that he never resected the rib unless the case was septic and that he obtained quite sufficient drainage without this. He thought that bronchial breathing could be heard, and especially in children, when the layer of fluid was thin. He had met with cases of fœtid empyema on the right side and was of opinion that they were the result of lymphatic infection from abdominal abscesses. It was much more common to meet with a mixed infection in adults, and such the views held by George Balfour, Chaveau, Marey, and others that murmurs were due to the vibrations of the "fluid veins" formed in the space beyond the narrowing. The difficulty in explaining the mitral regurgitant murmur on this theory was that it was heard at a point (the apex) in the opposite direction to the "fluid vein," which was directed towards the auricle; no explanation quite satisfactory had ever been offered. Dr. Bradshaw's explanation was that the sonorous "fluid vein" lay between the two curtains of the mitral valve and that its vibrations transmitted to the cone of blood passed through the thin walls without damping and set up vibrations in the ventricle. The vibrations were heard best at the apex, because the walls of the ventricles were thinned at this spot and this spot was most accessible to auscultation. He exhibited an apparatus constructed to show that sonorous vibrations could under similar conditions be conducted in a retrograde manner.—The paper was discussed by the PRESIDENT, Sir JAMES BARR, Professor L. R. WILBERFORCE, Dr. J. LLOYD ROBERTS, and Dr. R. J. M. BUCHANAN, and Dr. BRADSHAW replied.

The Production of Pseudo-arthrosis at the Hip-joint.—Volkmann's Ischæmic Paralysis.—Paralytic Calcaneo-cavus.—The Diagnosis and Treatment of Ectopic Gestation.

A MEETING of this society was held on Jan. 30th, the PRESIDENT being in the chair.

Mr. ROBERT JONES described his operation for the Production of Pseudo-arthrosis at the Hip joint without disarticulation of the femoral head. The great trochanter was first separated from the shaft by a broad osteotome and the neck of the femur either divided or removed, and the trochanter was screwed on to the head of the femur which lay in the acetabulum. The operation might be employed in all varieties of bony ankylosis but was eminently suited for old people with malum coxæ senilis where the shock of disarticulation was serious. Mr. Jones also described his procedure in the treatment of Volkmann's Ischæmic Paralysis and his operation in Paralytic Calcaneo-cavus.—The communication was discussed by the PRESIDENT, Mr. W. T. THOMAS, Mr. G. P. NEWBOLT, and Dr. J. H. ABRAM, and Mr. JONES replied.

Dr. H. BRIGGS read a paper on the Diagnosis and Treatment of Ectopic Gestation mainly founded upon a clinical study of 124 cases of interrupted early gestation marked by physical signs and symptoms at or before the end of the second month. Deducted from an inclusive total of 139 cases, all of them treated by operation, the 124 cases left 15 others, nine at from two to six months, two at six months, three about the full term, and one nine years after the full term, not included in the paper. The earliest disturbances amongst the 124 early ectopic gestation sacs occurred after intervals of six, 10, and 18 days beyond the cessation of a previous normal and regular menstruation. For the group of clinical symptoms and signs indicative of these disturbances Dr. Briggs 15 years ago had instituted and since adopted the term *peritoneal crisis*. He maintained that the symptoms and signs of sudden onset were often moderate or mild and that even trivial, locally recurrent pains, together with slight, irregular menstrual and intermenstrual blood loss, were not to be construed as harmless or insignificant until the physical signs had been closely watched or waited for. A more prompt appreciation of their significance and of what may lie before the patient would lead to earlier and easier and safer operations and to the more frequent recognition (with the Trendelenburg position for operation) of "unruptured tubes" and a little free intraperitoneal blood even in cases where the acute peritoneal crisis had been recent and severe. To postpone operation was to incur adhesions and hæmatocele sacs in their various forms. The peritubal (Sänger and Taylor) and the paratubal (Sampson Handley) hæmatocele sacs for their intact removal must be in a suitable physical condition; earlier and later in their course the physical conditions might defy intact removal. Intact removal was not indispensable, but the handling of organised and organising tissues, especially of adherent blood clots, or simply draining them, did not diminish the post-operative risks. Localised hæmatocele sacs as intraperitoneal formations subsequently to originally free intraperitoneal hæmorrhages possessed a stage at which there was both free and localised blood; the free blood outside the hæmatocele sac in process of absorption might be accepted as evidence of secondary rupture of the tubal or hæmatocele sac. Dr. Briggs believed that the older statistics of the prevalence of tubal rupture were inaccurate in consequence of the frequency with which gestation sacs were torn or ruptured by the fingers of the operator. In the future the continued use of the Trendelenburg posture, lending sight and light to the lower abdomen, would show, as it had shown in his more recent experience, that gestation sacs before operation were rarely ruptured. Werth and Taylor and Bland-Sutton had established their respective contributions to the process of tubal abortion. Dr. Briggs produced old gestation sacs, nine years old downwards, to demonstrate what may remain in a latent or an active form in the patient after apparently successful expectant treatment. During the first ten years up to the end of 1897 one vaginal and 20 abdominal sections, compared with the second ten years 17 vaginal and 101 abdominal sections, denoted a change from expectant to operative methods in his practice. He showed from nine of his cases bilateral lesions, on one side a tubal gestation sac and on the other a pyosalpinx once; a small ovarian cyst twice; and old, adherent, inflamed tubes six times, masking the diagnosis of ectopic gestation from the symptoms. A three years old and a recent tubal pregnancy on opposite sides coexisted in one case. A second tubal pregnancy on the opposite side had been treated by a second operation in three of his patients. Dr. Briggs referred to a paper which he himself read in 1897 in which he had produced evidence that intraperitoneal hæmorrhage and hæmatocele were occasionally associated with lesions other than those of ectopic pregnancy. The very rare rapid fatalities associated with tubal rupture formed a very small class of their own; operative treatment if at hand was almost excluded by the brief space of time available. "To operate," says Dr. F. H. Champneys, "during the state of shock is in many cases to kill the patient." Dr. Briggs said that he had invariably acted on this principle and he showed a series of ectopic sacs successfully removed from patients after they had recovered partially or wholly from a peritoneal crisis. The severity of a peritoneal crisis was no certain measure of the amount of hæmorrhage. He was of opinion that, with this exception, delay in the operative treatment of ectopic gestation increased its dangers. There were two deaths following operative treatment amongst his 124 cases: (*a*) after an unusually troublesome and risky operation amidst dense adhesions in a patient who had refused operation for appendage disease three months previously; and (*b*) after the operation for abdominal drainage of a very large hæmatocele in a very anæmic woman; death resulted from anæmia.—The paper was discussed by the PRESIDENT, Dr. T. B. GRIMSDALE, and Dr. J. GEMMELL, and Dr. BRIGGS replied.

Ascites and Tumours of the Ovary.—Exhibition of Specimens.

A MEETING of the pathological section of this society was held on Feb. 6th, the PRESIDENT being in the chair.

Dr. E. EMRYS-ROBERTS read a paper upon Ascites and Tumours of the Ovary. After a brief historical sketch of the subject he pointed out that the tendency of modern investigation was to assign to the cells of the peritoneum a more active rôle in the production of ascites than was formerly thought to be the case. Malignant disease of the peritoneum might possess an irritative or toxic property and the ascites might be called a peritonitic exudation as truly as in the case of infective peritonitis. In certain cases the ascites might possibly be the product of the cancerous growth. Ascites accompanying tumours of the ovary might result from certain necrotic changes in the tumours or from torsion of their pedicles. At other times the fluid might be accounted for by concurrent disease, while in certain tumours the ascites was actually the product of the epithelium of these new growths, as, for example, superficial papillomata and cystomata with ruptured walls.—Dr. H. BRIGGS thought that the needful work in reference to hydroperitoneum and papillomatous growths had yet to be done. So far the evidence was inconclusive.

Dr. JOHN HAY showed a Saccular Aneurysm of the Aorta of the size of a small orange situated beyond the origin of the left subclavian artery. Death was due to rupture into the left pleural cavity. Blood had previously leaked into the anterior wall of the pericardial sac forming a large hæmatoma in the tissues of the pericardium and leading to dyspnœa. The patient survived the rupture for four days.

Mr. G. P. NEWBOLT showed a Volvulus of the Small Intestine removed from a boy, aged 10 years, who was admitted with symptoms of intestinal obstruction. The upper part of the jejunum was twisted around a large caseous mesenteric gland which had been torn open by the torsion the uterus are mainly to be found in the connective-tissue sheaths of the vessels. The description given of the anatomy and etiology of prolapse of the pelvic organs is founded on a careful examination of no less than 40 specimens of this condition, all of which were very exhaustively studied either by means of sections or of dissections. A large part of the work consists of 60 plates illustrating 34 of these cases. These full-page plates, many of them coloured, are beautifully reproduced and are of the highest artistic and scientific value.

The anatomical changes which occur in all the various structures involved in cases of prolapse are considered in full detail and then the authors pass on to the most interesting part of their work—namely, that dealing with the etiology of this common condition in the female. As a result of their anatomical and other researches the authors favour the following explanation of the occurrence of prolapse of the uterus. They believe that a prolapse will occur when the opening normally existing in the pelvic floor is insufficiently closed so that it forms what may be termed a "hernial aperture." Any increase in the intra-abdominal pressure tends to force through this aperture all those organs or parts of organs which may be situated over it or in its immediate neighbourhood. If, for example, the whole of the uterus is placed over the opening, total prolapse of that organ will result from such increased intra-abdominal pressure; while if a part only of the uterus is so situated some form of partial prolapse is likely to occur. The intra-abdominal pressure tends to force through the imperfectly closed opening in the pelvic floor that part of the uterus lying over it, but the rest of the organ by the same pressure will be firmly pressed against its underlying supports and so retained in its position. The natural resistance to any descent of the pelvic organs is derived from the support which they receive from the bony walls of the pelvis and the muscular pelvic diaphragm. Any injury leading to stretching of these soft parts and insufficiency of their normal power of supporting the pelvic organs and closing the aperture in the pelvic floor will inevitably produce a tendency to prolapse, as will also a deficiency in the bony walls of the pelvis, as is exemplified in cases of split pelvis in which secondary prolapse is not uncommon. On such a theory not only can all the common forms of prolapse be readily explained but the anatomical changes which are found in the different tissues affected can be adequately accounted for. It accounts for the elongation of the cervix and of the body of the uterus which is so often met with, for the different degrees of descent of the anterior and posterior vaginal walls, for the varying degrees of hypertrophy of the anterior or posterior lips of the cervix, and for the occurrence of congenital prolapse, especially when associated with spina bifida.

The book must be read to appreciate the large amount of evidence which is adduced in support of the theory put forward; for this we must refer our readers to the work itself and to a careful study of the illustrations of actual cases and dissections. Finally, after a chapter on the experimental study of the causation of prolapse of the uterus the authors consider shortly its treatment by pessaries and various operative methods.

The book is one of great interest and value, the amount of work which it embodies is prodigious, the illustrations are most excellent, and the whole work is worthy of the high reputation of the writers.

The Standard Family Physician. Three volumes. London and New York: Funk and Wagnalls Company. 1907.

THE title page to this publication is so striking that we have not copied its contents under the title of the work as is our usual custom when considering books sent to us for review. The work is termed "A Practical International Encyclopædia of Medicine and Hygiene, especially prepared for the Household." It is stated to have been "edited by" Sir James Crichton-Browne, M.D., LL.D., F.R.S., Sir William H. Broadbent, Bart., K.C.V.O., M.D., F.R.S., Dr. Alfred T. Schofield, Professor Karl Reissig (Hamburg), and Dr. Smith Ely Jelliffe (New York), "with the assistance of many European and American specialists in the treatment of diseases and experts in medicine and surgery." Reproductions of photographs of Sir James Crichton-Browne, the late Sir William Broadbent, and Dr. Schofield respectively appear as frontispieces to the three volumes into which the work is divided. The work commences with an unsigned article on "The Family Physician"; then follows a paper by Dr. Schofield entitled "The Journey of Life and the Laws of Health"; next appears a reprint of Sir James Crichton-Browne's Cavendish lecture on "Dreamy Mental States"; and next a contribution by the late Sir William Broadbent on the Prevention of Consumption and Other Forms of Tuberculosis, written in a popular manner and containing information likely to be useful to lay readers.

The next portion of the work is taken up with an article entitled "Structure and Functions of the Healthy Human Body." The information contained therein would be redundant to a medical practitioner and useless to a lay reader. The remainder of the publication is devoted to a sort of medical dictionary, stated (in an advertisement) to be "the greatest international work of medical reference for the home that has ever been produced." Perhaps the less said about this strange production the better. We admit that some of the information given may be useful "in the home," but a large portion is likely to be only misleading and to give rise to unnecessary alarm to those not acquainted with medical science. Some of the directions given are peculiar. For instance, under the heading "Death" we find the following: "Quiet and consolation should surround the dying person. He should be kept clean and comfortable until he has drawn his last breath, and even after that."

The volumes are profusely illustrated. Many of the diagrams are, in our opinion, totally unsuited for a work "for the home," and some are liable to give rise to false impressions, especially the diagrams supposed to illustrate "areas of pain." The books when sent to THE LANCET Offices were accompanied by an advertisement. We feel sure that the physicians whose names appear on it could not have been cognisant of the manner in which their participation in the publication would be made use of.

The Hygiene of Armies (Περὶ Ὑγιεινῆς τῶν Στρατευμάτων). By S. K. ZAVITZIANOS, M.D. Corfu: A. Lantza. Pp. 253.

Dr. Zavitzianos deals in this interesting book very thoroughly with the numerous aspects of an important subject. Though written in Greek, and more especially in relation to the Greek army, the book may be said to be of general interest, a careful and minute study of records and official reports having enabled the author to marshal a great array of facts and statistics in relation to the practical working of the Army Medical Services in all European countries, as well as in Japan, Persia, Siam, and the United States, from about the time of the Crimean war to the present day. The author's survey of the hygienic conditions prevailing in the different armies in peace and war time, but especially the latter, and his study of the subject generally have resulted in a firm conviction on his part that no great measure of success can be obtained in the medical treatment of troops by the system of employing a medical staff exclusively devoted to military service and unsupported by civilian coöperation. Basing his statement on known events in almost all recent wars, he affirms that no army medical service organised in this way has been, or is bismuth powder. If there was constipation, and there usually was, a rhubarb pill or some other simple vegetable laxative might be given twice or three times daily after food, so as to insure a natural action of the bowels once daily without straining and without purging. He did not give saline purges in gastric ulcer. Local applications of heat to the abdomen gave ease to the patient. All severe forms of counter irritation, such as blisters and mustard poultices, he never used; iron was most undesirable for patients suffering from gastric ulcer, however anæmic they might be. In the treatment of hæmatemesis he adopted the same plan: absolute rest of body and mind, by morphine if necessary, and water drinking sufficient to allay thirst, not by teaspoonfuls but three or four ounces at a time He had no faith in so-called hæmostatic drugs in internal bleeding, but saw no objection to the use of such harmless and tasteless things as chloride of calcium, for example. Suprarenal extract might be, perhaps should be, used, but it was a powerful substance and should be given with care. Patients suffering from recent and severe hæmatemesis were never hungry and therefore did not require food. After three clear days from the cessation of the hæmatemesis food such as meat, eggs, and stale bread might be given, if the patient wished but not otherwise. After hæmatemesis the patient should be kept in bed until the anæmia had largely, if not entirely, disappeared.

Mr. MOYNIHAN dealt with the Surgical Treatment of Gastric Ulcer. He differentiated between acute ulcer, in which only the mucous surface of the stomach was as a rule involved, and chronic ulcer, in which the destructive and reparative processes had together involved all the coats of the stomach, so that the ulcer was a visible, palpable, and demonstrable lesion. In acute ulceration surgical treatment was never necessary on account of hæmorrhage and rarely on account of perforation. In his own series of 37 cases of perforating ulcer there was only one in which the ulcer was acute; in the remainder it was a chronic ulcer, the symptoms of which had been present for months or years and had been recently more acute. Gastro-enterostomy in addition to closure of the ulcer was called for if there were other ulcers or if the closure of the ulcer was likely to cause obstruction. Hæmorrhage in chronic ulcer rarely called for urgent operation; an interval of freedom from bleeding should be chosen. Excision of the ulcer, or its infolding, the vessels supplying the ulcer being secured, and gastro-enterostomy were usually to be practised. Chronic ulcer of the stomach or of the duodenum was held to be a condition which should in all cases be treated by operation. The difficulty in some cases in arriving at a diagnosis was referred to and the opinion expressed that in most cases an exact diagnosis was attainable, and that in many the position of the ulcer could be predicted. If, however, after the abdomen had been opened, an inspection of it revealed no lesion, there was no indication for any operation upon the stomach itself. In no circumstances whatever and in compliance with no persuasion, however insistent, should the surgeon consent to perform gastro-enterostomy in the absence of definite demonstrable organic disease. If an ulcer were found near the pylorus, on either side, gastro-enterostomy should be performed, and, if possible, the ulcer should be infolded, to prevent perforation or hæmorrhage, both of which had occurred after gastro-enterostomy. If the ulcer was on the lesser curvature in the cardiac half of the stomach it should be excised; gastro-enterostomy in such cases gave only slight and temporary relief. When multiple ulcers were present in the pyloric region, or when a doubt existed as to the malignancy of the condition, Rodman's operation, excision of the ulcer-bearing area, was indicated. The method of gastro-enterostomy which gave the best results was the posterior operation, the jejunum being applied almost vertically to the stomach, and the anastomosis being made as close to the flexure as possible.

The PRESIDENT, Dr. J. E. EDDISON, Mr. E. SOLLY, Mr. W. R BATES, Mr. J. STEWART, Mr R. LAWFORD KNAGGS, Mr. N. PORRITT, Dr. A. CHRISTIE WILSON, Dr. E. S. LEWER, Mr. H. COLLINSON, Mr. H. H. GREENWOOD, and Dr. H. SECKER WALKER took part in the discussion, and Dr. BARRS and Mr. MOYNIHAN replied.

Mr. H. LITTLEWOOD showed: 1. A patient suffering from Pyloric Stenosis on whom gastro-enterostomy had been performed in June, 1907. The patient's weight before operation was 3 stones 7 pounds, and the present weight was 7 stones 12½ pounds. 2. A specimen of Thrombosis of some Vessels in part of the Transverse Colon producing Intestinal Obstruction. 3. A Gall-bladder, with Stones, removed from a girl 18 years of age. The gall-bladder was contained in a complete mesentery extending from the liver to the colon.

Dr. J. B. HELLIER showed a Sarcomatous Growth removed from an Old Abdominal Cicatrix.

Mr. J. F. DOBSON showed a specimen from a case of Abscess in the Great Omentum with Diffuse Peritonitis. Almost the whole of the omentum was removed.

Specimens and cases were also shown by Mr. WALTER THOMPSON, Dr. CARLTON OLDFIELD, Mr. E. WARD, Mr. KNAGGS, the PRESIDENT, and Mr. MOYNIHAN.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Removal of Submaxillary Gland.—Electrolysis in Medicine and Surgery.—Empyema.

A MEETING of this society was held on Feb. 5th, Dr. GEORGE HUNTER, *Vice-President, being in the chair.*

Mr. F. M. CAIRD demonstrated a patient after removal of a Submaxillary Gland. The patient had been shown at the previous meeting as one from whom Mr. Caird had removed one half of the tongue for carcinoma. The submaxillary gland after this became enlarged and cirrhotic but Mr. Caird did not think that it was the seat of cancer. Most of the surgeons present at the meeting recommended removal as they thought that it was malignant. The gland was removed and though examined carefully by pathologists no trace of malignant disease was found. It was merely an inflamed and cirrhotic gland. This was important as regards the prognosis.

Dr. DAWSON F. D. TURNER read a paper on Electrolysis in Medicine and Surgery. He said that the human body was an electrolyte, and electrical currents were only conveyed through it by the migration of ions (electrified particles of matter). Only those drugs which broke up into ions could be made use of—e.g., aqueous solutions. Oils, alcohols, and glycerines did not form ions; the spiritus chloroformi and the glycerinum acidi carbolici could not be introduced electrolytically; for this reason they were more toxic in aqueous solutions when taken by the mouth. If an individual were to place each hand in a separate basin of salt water, and if these were connected with the terminals of a source of electric supply, then at the anode or basin connected to the + pole the body would lose its anions and receive cations, while at the cathode or basin connected with the – pole the body would lose its cations and receive anions. The anions were constituted by the acid radicle or elements and the cations by the metallic radicle or metals. Thus oxygen, chlorine, sulphion, and hydroxyl were anions; while hydrogen, sodium, and copper were cations. When sodium chloride was dissolved in water its molecules dissociated into ions or particles with opposite electrical charges; the anions were charged negatively and would therefore be attracted to the anode, and the cations were charged positively and would be attracted to the negative pole or cathode. In this case Na + was the cation and Cl – was the anion. At the anode the body would yield up chlorine and receive sodium, while at the cathode it would give up sodium and receive chlorine. Between each electrode there would be a migration of ions, the Cl – ions would be moving to the anode and the Na + ions to the cathode. If a piece of raw beef were taken and electrodes applied to either side with some blotting paper soaked in a solution of potassium iodide under the – electrode and some blotting paper soaked in starch between the + electrode and the beef, it would be found that on passing a current the blotting paper at the + pole would become blue, showing that iodine had been carried through the beef. In the same way metallic ions might be conveyed into the tissues of living beings. A rabbit might be poisoned by having strychnine carried into its tissues from the anode moistened with the salt of this alkaloid. To what useful purposes could this introduction of ions into the body be put? Rodent ulcer, parasitic affections, sinus and fistula, ankylosis, sclerosis, fibrous adhesions, stricture, tic douloureux, neuralgia, sciatica, and rheumatic and gouty conditions were all benefited by this treatment. Leduc reported the complete cure at a single sitting of a case of rodent ulcer by the introduction of the zinc ion from sulphate of zinc. As a rule, however, more than one application was necessary. The ulcer should be cleaned and from which we have recently reviewed. It is a pleasure to find that the book remains essentially the same as in the first edition. It has not been overweighted with new matter and it still, better than most books, enables the reader to distinguish between facts and the inordinate accretions of conjecture. No better introduction to the subject could be placed in the student's hands.

JOURNALS AND MAGAZINES.

Proceedings of the Royal Society of Medicine. Vol. I., Nos. 2 and 3.—The excellent start which the Royal Society of Medicine made with the first number of its proceedings has been well maintained in its successors. It is not our purpose to review these publications at any length as the papers and cases with which they deal have as a rule been reported in our columns before their appearance in the society's literature. The second number records many interesting cases in the Clinical, Dermatological, and Laryngological Sections, the last part of the important debate on Pneumonia, followed by a paper on the Pathology of Epilepsy, by Dr. Alfred E. Russell, with the subsequent discussion, in the Medical Section, and in the remaining sections the following cases: The X Ray Diagnosis of Renal and Ureteral Calculi, by Dr. G. Harrison Orton; Medical Inspection in Schools: the Gloucestershire System, by Dr. Myer Coplans; Pubiotomy, by Dr. Thomas Wilson; An Analysis of 274 Additional Cases of Goitre Removed by Operation, by Mr. James Berry; the Therapeutics of Indigestion, by Dr. William Murray; Some Tropical Diseases and the Remedies required for their Treatment and Prophylaxis, by Mr. James Cantlie; A Contribution to the Study of the Relationship between Avian and Human Tuberculosis, by Mr. S. G. Shattock, Dr. C. G. Seligmann, Mr. L. S. Dudgeon, and Dr. P. N. Panton; Some Experiences with the Tuberculin Ophthalmic Reaction, by Mr. L. J. Austin and Dr. Otto Grünbaum; Abscess of Bone caused by an Intermediate Bacillus (P.) allied to B. Paratyphosus, by Dr. F. G. Bushnell; Some Notes on the Growth of the Jaws, by Mr. J. T. Carter; and the Effects of Chronic Suppuration in the Molar of a Horse, by Mr. J. G. Turner. In the January number (No. 3) there are reports of cases and specimens from the Clinical, Dermatological, Laryngological, Obstetrical, Otological, and Surgical Sections; a Presidential Address to the Otological Section, by Dr. Peter McBride, dealing with the development of aural surgery; a discussion on the Diagnostic Value of the Roentgen Rays in Diseases of the Chest, introduced by Dr. A. Stanley Green, and amongst the papers are the following: On the Present Means of Combating the Plague, by Professor W. M. Haffkine, C.I.E., and Protection of India from Invasion by Bubonic Plague, by Dr. J. Ashburton Thompson; Some Peculiarities of Cerebral Gummata, by Dr. J. S. Collier; the Supports of the Pelvic Viscera, by Dr. W. E. Fothergill; a Case of Complete Gastrectomy, by Mr. B. G. A. Moynihan; Cases of Cholecystectomy, by Mr. J. D. Malcolm; the Action of Digitalis on the Human Heart, by Dr. James Mackenzie; and the Reminiscences of an Apprentice Fifty Years Ago, by Mr. W. Soper.

The Journal of Nervous and Mental Diseases (New York).—In the December, 1907, issue of this journal there is an interesting paper by Dr. Lewellys Barker and Dr. Frank J. Sladen of Baltimore on Acrocyanosis Chronica Anæsthetica with Gangrene; its Relations to Other Diseases, especially to Erythromelalgia and Raynaud's Disease. Also among the proceedings of the American Neurological Association reported in this number will be found a discussion on Heredity in Diseases of the Nervous System, in which many well-known authorities expressed their opinions. The subject is viewed from a wide standpoint and the report of the proceedings will be found instructive to anyone collecting data on this topic. The account of the New York Neurological Society contains a discussion on the Antisyphilitic Treatment of Tabes and Paresis, and most of the speakers were agreed that this form of treatment was very unsatisfactory in these diseases and indeed that in many instances it aggravated rather than relieved the symptoms; further, that probably in most of those cases in which permanent good was derived the condition was rather one of pseudo-paresis than the true disease. This number also contains other matter of instruction and interest.

New Inventions.

X RAY PLATES.

We are glad to find that at last a really serious effort is being made to produce a satisfactory x ray plate in this country. We have received from Ilford, Limited, Ilford, London, E., samples of x ray plates which as regards the ultimate result quite equal and even excel that of any imported plate we have ever tried. They give full density, plenty of contrast, and abundant detail. It must be admitted, however, that they require a rather longer exposure than some plates of foreign make. While the length of exposure is a matter of secondary importance in most cases, there is no doubt that other things being equal radiographers will unquestionably use those plates which require the least exposure, not only as an extra precaution against any undesired epilation or dermatitis but in the radiography of fidgety people and children, the saving of time generally, and on account of the reduced wear and tear of x ray tubes. No doubt in due course emulsions will be prepared having a greater sensitiveness to the x rays.

There would appear to be some confusion in the minds of the makers as to the relation that exists in the sensitiveness of the haloid salts of silver to ordinary daylight and to the rays from an x ray tube. As a matter of practical experience we have found that all ordinary photographic plates, whether "process," "slow," "extra rapid," or by whatever term they are described, have about an equal sensitiveness to the x rays, the "rapid" varieties not necessarily being more rapid than the slower grades. Another noteworthy fact is that it is difficult, and at times impossible, to get sufficient density when an ordinary photographic plate is used for radiographic purposes. This seems to be due to the thinness of the coating, which, though thick enough for the purposes of ordinary photography, does not react correspondingly under the influence of the x rays. To get over this difficulty thicker coatings have been used, and while this scheme answers up to a certain point the fact remains that some x ray plates of foreign manufacture produce results with comparatively brief exposures such as we have been unable to obtain with plates of British manufacture. In justice to the Ilford x ray plates we should say that in every case where we have used both an Ilford plate and one of the best obtainable plates of foreign origin upon the same part of the same patient and under exactly similar conditions except the length of exposure, the resulting negative has been better in the case of the Ilford. In all cases the plates were fully exposed, so that longer exposure in either case would have been detrimental. We welcome and recommend the Ilford x ray plates. Ilford, Limited, appear to be working along the proper lines and we fully expect that before very long we shall have available an x ray plate of home manufacture at least the equal of any other.

University of Cambridge.—The following appointments have been made:—Electors to the following Professorships: Anatomy, Dr. D. MacAlister; Medicine (Downing), Sir Lauder Brunton; Physiology, Dr. W. H. Gaskell; Surgery, Mr. H. H. Clutton; and Pathology, Dr. L. Humphry.—Dr. Humphry has been coöpted a member of the degree committee of the Special Board for Medicine.—Mr. Raymond Johnson, M.B., B.S. Lond., F.R.C.S. Eng., has been appointed an Examiner in Surgery for the Third M.B. in place of Mr. H. G. Barling who is unable to examine.—Mr. J. S. Gardiner, M.A. of Caius College, has been reappointed demonstrator in animal morphology for five years.

were not so rapidly recovered from as those due to simple pneumococcal infection.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—A meeting of this society was held on Jan. 29th, at 20, Hanover-square, London, Dr. A. F. Street (Westgate-on-Sea) being in the chair.—Dr. R. *Fortescue Fox re-introduced* the adjourned discussion on the paper of Dr. W. Edgecombe (Harrogate), on Blood Pressure in Spa Practice, which was read on Dec. 11th, 1907. He dwelt upon the importance of vaso-motor tone as a factor in arterial blood pressure. Abnormalities of pressure were, in fact, in the first instance nervous disorders, and balneological treatment, here as elsewhere, took effect to a large extent through the nerve centres. The effect of baths (sub-thermal) at a temperature between that of the blood and the skin was unquestionable in reducing excessive vaso-constriction and therefore blood pressure. Dr. Fox described a hereditary type of "poor circulation" in gouty families, for which hyper-thermal spa baths afforded the best treatment. In middle and later life a judicious course of cooler baths relaxed arterial spasm and delayed for many years the development of incurable high tension. In disorders of the climacteric and other vaso-motor ataxias spa treatment was usually efficient, but sub-thermal baths must be employed with a sedative effect in view.—Mr. J. P. Lockhart Mummery said that he had done a lot of experimental work upon blood pressure and that in his opinion it was advisable to use only the pulse obliteration point (systolic pressure) and that the so-called diastolic pressure was quite useless and untrustworthy, and there was no proof that it was diastolic pressure; in fact, experimental evidence was opposed to its being diastolic pressure. He gave the figures from a series of experiments showing that the systolic pressure as estimated by the Riva-Rocci instrument is correct to within two millimetres of Hg. He also pointed out that the Riva-Rocci instrument with a straight manometer tube is the most trustworthy, and that with the U tube any error of reading was doubled.—Dr. Alfred Mantle (Harrogate) said that disturbances of the peripheral circulation materially affected the general blood pressure. Several types of circulation were noticeable. Cold subjects having a tendency to an abnormal contraction of the peripheral circulation were met with, and as a result of a diminished quantity of blood in the cutaneous reservoir, there was an increased amount in the splanchnic and other areas which in time might produce gastric, hepatic, renal, or cardiac complications. In another type the periphery was dilated, and such people were always warm, and he had observed them to be more subject to cutaneous diseases, also to glycosuria. The importance of what might be called the "skin heart" in regulating the blood pressure was too little appreciated.—*Dr. William Ewart referred* to the prevailing view that the tortuosity of arteries is the result of long-continued high pressure. In his experience tortuosity sometimes occurred in *hypotensive subjects* and should not therefore be accepted as positive evidence of high tension.—Dr. Street said *that* abnormalities of blood pressure were undoubtedly due to vaso-motor disorder, but peripheral vaso-motor abnormality did not connote serious disturbance. The wide variation of individual *vaso-motor* control in man was illustrated by a consideration of the *functions of the* vaso-motor system in the woodpecker, the sloth, and marine mammalia generally. If arterial tortuosity was the result of high tension, what was the cause of the tortuosity common in superficial veins in the lower extremity?—Mr. C. W. *Buckley* (Buxton) said that the treatment of the early stages of high blood pressure by sub-thermal baths, as suggested by Dr. Fox, was most important and at certain continental spas had been made a speciality. The treatment of gout in Buxton for generations had followed those lines, showing that empirical methods were based on sound principles. Referring to the remarks of another speaker, he pointed out that there were many English springs of great value as diuretics and that it was not necessary to go abroad for such waters.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on Feb. 7th, Dr. W. *Langdon* Brown, *the President*, being in the chair.—Dr. T. G. Stevens read a paper on the Nature and Treatment of Puerperal Eclampsia. After defining the condition and enumerating its classical symptoms he said that scanty urine and a low urea coefficient were more important signs than the amount of albumin. As regards pathology, the most widely accepted view was that of auto-intoxication, the mother poisoning herself by the effects of constipation and by the *products of metabolism. The liver failed* to alter the toxins formed by metabolism and the kidneys were unable to excrete them, so albuminuria and eclampsia were produced. Post mortem, there was necrosis of the renal epithelium with fatty and granular degeneration—i.e., the kind of kidney found in diphtheritic poisoning. The liver nearly always showed small hæmorrhages and patches of necrosis and a fatty degeneration as seen in acute yellow atrophy. Death might be directly due to the toxins, to œdema of the lungs, to sepsis as the result of operation, or to poisoning by such drugs as strychnine, morphine, and pilocarpine The prognosis was bad if the fits were more than 15 in number, if the temperature progressively rose, if the urine was almost *suppressed*, and *if delivery* could not be quickly performed. In the treatment of fits morphine was the best method and it should be given in large doses as there was no danger to the kidneys, for morphine dilated the renal blood-vessels and caused diuresis. Half a grain *hypodermically* should be given at once, and if in two hours the patient was not under its influence another quarter of a grain should be given. Chloroform did not abolish fits but only decreased their violence. The toxæmia ought to be treated by infusion of saline solution, croton oil, washing out the *stomach* and the colon, and venesection in a *full-blooded* plethoric patient. Delivery stopped the fits in 54 per cent. of the cases, so if the patient was in labour she should be delivered as soon as possible.—Dr. Eardley L. Holland, *who* took part in the discussion, advised the German method of immediate rapid delivery, whatever the stage of labour, without any preliminary palliative measures. The cervix could be rapidly dilated with Bossi's dilator, but if it were still intact vaginal Cæsarean section should be performed. He laid it down as a rule that if the first convulsion were severe rapid *delivery ought to be done*, but if the first convulsion were mild then palliative measures might be tried.

Reviews and Notices of Books.

Anatomie und Aetiologie der Genitalprolapse beim Weibe. (Anatomy and Etiology of Prolapse of the Female Genital Organs.) By Dr. JOSEF HALBAN and Professor JULIUS TANDLER. With 60 plates and 44 figures in the text. Vienna and Leipsic: Wilhelm Braumüller. 1907. Pp. 273. Price, paper, M.18; M.15. Bound, M.21; M.17.50.

THE work already published by *Professor* Julius Tandler and Dr. Josef Halban on the "Topography of the Ureters" is of so high an order of merit that we began the perusal of this work with a feeling that it was sure to be of great value and interest. Nor are we at all disappointed. The *book* contains a very full and extremely able account of the anatomy and etiology of prolapse of the uterus, preceded by a description of the normal position and means of *support* of the female pelvic organs, and followed by some considerations *on the treatment* of prolapse of the uterus by pessaries and by operations.

From their anatomical researches the authors come to the conclusion which anyone who has studied the subject would expect—namely, that all the tissues connected on the one side to the uterus and on the other to the pelvic walls play a part in the fixation of the pelvic organs. The structures, however, which overcome the tendency to prolapse of the pelvic organs resulting from an increase in the intra-abdominal pressure, and which play the most important part in maintaining the position of the pelvic contents, are the muscles of the pelvic floor. How important a part they play is well illustrated by the conditions met with in cases of *congenital* prolapse dependent on the presence of a spina bifida in which the fourth sacral nerve is involved. We need hardly say that the conclusions arrived at *do not* in any way favour the theory which has recently been put forward that the supports of and carried out by Major GEORGE LAMB, I.M.S., Captain W. GLEN LISTON, I.M.S., and the other members of the working commission of the committee both by means of plague-stricken rats kept in experimental "go-downs" and by observations in private houses. These experiments proved conclusively that the rat does spread plague through the agency of the fleas which have bitten it. The other piece of evidence has been brought forward by Dr. J. ASHBURTON THOMPSON, the permanent head of the Department of Public Health in New South Wales, whose report on the mode of spread and prevention of plague in Australia appeared in abstract in THE LANCET of Oct. 19th, 1907, p. 1104. He demonstrated that in the Sydney epidemics there has always been a close association between plague in rats and man, the one preceding the other, and that the chronicity of the epizootic is an important clue to the recurrence of the disease in man. Dr. THOMPSON does not consider the common European rat, Mus decumanus, immune from the possibility of acquiring plague but fully accepts the doctrine of the spread of plague by the fleas which infest the rat. Another disease which has been certainly laid to the score of Mus decumanus is trichinosis which is fortunately very rarely seen in this country but is a serious menace to those peoples who habitually eat half-raw and often rat-fed pork.

The chief indictment which Sir JAMES CRICHTON-BROWNE brought against the English rat was the economic one when he said:—

> No more destructive animal existed. Nothing came amiss to its chiselling teeth and insatiable maw. It made heavy depredations on fields of corn, on stack-yards, granaries, and ship cargoes; it devoured eggs, killed poultry and game, made unwelcome visits to dairies and pantries, butchers' shops, and bakeries; it gnawed through lead pipes, causing household floods, and it was even suspected of arson by nibbling the insulating material on crossing electric wires and so short-circuiting them.

This is doubtless all very true and even the most tender-hearted of animal lovers would scarcely urge as a serious excuse for such conduct that the rat must gnaw not only for food but in order to keep down his rapidly growing incisor teeth which otherwise might kill him by a literal lock-jaw; but to our minds the indictment of the rat on the score of his menace to public health is far heavier than any that can be brought on the score of his mischievous propensities. It is interesting to note that the rat has not been always an object of execration. Amongst Scandinavian and Teutonic races rats and mice were reverenced as being the souls of the dead, while BARING-GOULD in his paper on the famous Bishop HATTO myth, shows that the army of rats which devoured the unfortunate prelate undoubtedly symbolised the host of poor wretches burnt by him in the barn. He points out, however, that Bishop HATTO was a most maligned and kind-hearted man, and that stories of similar character have been told of prominent personages in Scandinavia, Switzerland, Bavaria, Poland, and even Asia. BARING-GOULD thinks the origin of them may have been human sacrifices of chieftains by savage tribes in time of famine, the victims being given as a propitiation to be devoured by hungry rats. If rats were not liked in ancient days they would seem to have been respected, and this feeling still obtains among primitive or superstitious folk. It is certainly present in India, to her misfortune.

We consider that the public attention which has been called by modern scientific work to the peril which rats form to a community is a matter of great importance to our Empire, and we welcome the formation of a league for their extermination, hoping that the public mind will not relegate the scheme to the ranks of the faddists. But the new association has an enormous task before it if its members seek to exterminate the countless millions of rats, of which most are inaccessible, in the British Empire. An agressive policy has, it is true, been successfully carried out in places. In THE LANCET of Oct. 19th, 1907, p. 1099, we commented on the observations of Lieutenant-Colonel A. BUCHANAN, I.M.S., on the relation between the keeping of cats and the incidence of plague in Indian villages. He is convinced that cat-keeping abolishes the rats and consequently plague. The rat-catcher and his dog are time-honoured means of aggression, and another instance of the militant method has been successfully adopted in Jamaica where mongooses have been imported and have completely cleared the sugar plantations of rats by destroying their young, thereby saving a large proportion of the sugar crop. The experiments of the Plague Commission and the experience of Dr. THOMPSON, which he has laid before the Epidemiological Section of the Royal Society of Medicine,[1] tend to show that the most necessary means of meeting the rats in fighting plague is prophylactic and consists in rendering dwellings, and especially food-stores, rat-proof. Captain V. B. NESFIELD, I.M.S., has recently supplemented this suggestion by another, that the winter store of grain should be kept in detached granaries and not in native dwelling-houses. The crusade against rats, however, will not rest content with entrenching itself against the enemy's hordes, and it seems likely that science has provided us with a most potent weapon of offence in the form of a bacteriological virus intensely fatal to rats which readily feed on bait which has been charged with their doom. We have before us the prospectuses and testimonials of two preparations which are said to be poisonous to rats, setting up a quickly fatal disease, but to be harmless to man and the domestic animals. There is certainly a good deal of evidence adduced in their favour but an extended series of observations will be necessary before the efficacy of such measures can be proved.

◆

Pelvic Contraction.

IT is a matter for congratulation that amongst the women of this country cases of contraction of the pelvic measurements are not met with very frequently. Unfortunately, no recent investigations upon this point have been carried out by English observers in a sufficiently large number of cases to enable us to predict with certainty what percentage of such pelves will be met with in every 100 cases of labour. The marked discrepancies existing in the figures which have been collected by foreign observers are to be explained very largely by the fact that the definition of what constitutes a contracted pelvis is not a matter of entire agreement amongst obstetric writers. The one most commonly accepted is that which defines a pelvis as contracted when the degree of contraction is sufficient to interfere with the normal mechanism of labour although it may not retard the birth of ever likely to be, really efficient. The scheme proposed by Dr. Zavitzianos for the Greek army is to abolish the army medical service altogether and to organise a service of civilian medical men, to be called upon in time of war or whenever needed, not exclusively attached to the army but able to practise independently, and therefore with opportunities of keeping pace with new scientific developments and with liberty to specialise. This scheme is worked out and supported by many arguments, and the suggestion and discussion of it form the main purpose of the book which concludes with chapters on military buildings, on the food and clothing of troops, and on their intellectual development.

---

[1] THE LANCET, Dec. 7th, 1907, p. 1611.

Dr. Zavitzianos intends to publish a French translation of his book shortly and we are glad to learn this from him. French is more or less known to most medical men and many of our readers would, we think, like to have the information in "The Hygiene of Armies" before them. The similarity of Dr. Zavitzianos's views with those expressed by the Director-General of the Royal Army Medical Corps, Sir Alfred H. Keogh, in so many medical centres is noticeable, though our circumstances and those in Greece are so different. Of course there can be no idea with us of dispensing with our excellent army medical service, the hope is to reinforce it by an adequate and economical reserve.

Immune Sera: A Concise Exposition of our Present Knowledge Concerning the Constitution and Mode of Action of Antitoxins, Agglutinins, Hæmolysins, Bacteriolysins, Precipitins, Cytotoxins, and Opsonins. By Dr. CHARLES FREDERICK BOLDUAN, Bacteriologist, Research Laboratory, Department of Health, City of New York. Second edition, rewritten. London: Chapman and Hall, Limited. New York: John Wiley and Sons. 1907. Pp. 154. Price $1.50.

THIS little book gives a very clear and satisfactory account of the various bodies which are known to exist in immune serums. It starts with a short historical account of the subject and then describes the mode of preparation of diphtheria antitoxin. Ehrlich's theories as to the relations of toxins and antitoxins are next set forth and also the opposing views of Arrhenius and of Bordet. It is very properly stated that at present the exact truth is not determined. Agglutinins, bacteriolysins, hæmolysins, and precipitins are next discussed and the practical applications of our knowledge of these bodies to the recognition of blood-stains. Some good diagrams are given to explain the nature of group-agglutinins. Cytotoxins are briefly dealt with and the value of opsonic determinations is criticised; the author is impressed with the degree of error inseparable from the methods employed and also with the divergence between the clinical course of many cases and the fluctuations of the opsonic index. Three pages are devoted to the subject of snake-venoms but no allusion is made to the interesting work of Kyes in isolating the lecithids of cobra poison, chemical compounds of lecithin with the copula or amboceptor present in the venom. The final section is devoted to a discussion of the phenomena of serum-sickness in man and of the allied, if not identical, condition termed anaphylaxis as observed in experiments on animals. Dr. Bolduan appears to greater advantage as an original author than as a translator and gives a very readable account of the difficult and highly technical matters with which he deals. We commend the book to all who are desirous of gaining a first acquaintance with recent work in the field of immunity.

LIBRARY TABLE.

A Text-book of Organic Chemistry. By A. F. HOLLEMAN, Ph.D., F.R.A. Amst. Translated from the third Dutch edition by A. JAMIESON WALKER, Ph.D. Heidelberg, B.A.; assisted by OWEN E. MOTT, Ph.D. Heidelberg. Second English edition rewritten. London: Chapman and Hall, Limited. New York: Wiley and Sons. 1907. Pp. 589. Price 10s. 6d. net.—The multiplicity of organic compounds is an invariable stumbling-block to the student commencing to read organic chemistry and he had far better take as a first course a book which, like the one under review, presents a limited number of facts and yet gives prominence to the theory underlying the subject than one in which so many apparently disconnected details are dealt with. Professor Holleman's text-book is deservedly popular, the original Dutch edition having been translated into an English, a German, a Russian, and an Italian edition respectively. The success which has so far attended its publication is due, we think, to the author's gift of discriminating between principles and facts which are immediately essential to the beginner's grasp of the subject and those which, at all events, in his early studies, only conspire to upset, so to speak, his mental digestion by reason of their wealth and intricacy. Throughout the story is told step by step in simple terms, and it is not easy to preserve, as is done in this text-book, a continuity of treatment with such a vast subject as the chemistry of the carbon compounds. The present edition also is in touch with the results of recent developments, for in the chapter on the constitution of benzene the recent researches on this subject are discussed, which would appear to show that not one of the graphic formulæ suggested affords a completely satisfactory explanation of observed facts. The chapter on pyrrol also has been made to fall into line with the fruits of investigation contributed by Professor Ciamician in a recent lecture before the German Chemical Society. The nature of reactions is interpreted in the light of the theory of "ions." The translation is ably done and we have only noted two misprints, one in the author's preface to the first edition and the other in the heading on p. 447. It may be remarked also that the translator has retained the word "proteids" which English physiologists and chemists have agreed to call "proteins."

Die Experimentelle Diagnostik, Serumtherapie und Prophylaxe der Infektionskrankheiten. (*Experimental Diagnosis, Serum-therapeutics and Prophylaxis of the Infectious Diseases.*) Von Stabsarzt Professor Dr. E. MARX. Second edition. Berlin: August Hirschwald. 1907. Pp. 398. Price 8 marks.—We are glad to welcome a second edition of Professor Marx's little book. The main features of the former edition are preserved but the author has added chapters dealing with the general principles of immunity and with infections due to the bacillus fusiformis and to trypanosomes. He has also added an index which materially increases the value of the volume. Advances in knowledge since the first edition appeared have been so great as to necessitate the rewriting of much of the contents and the size of the whole has increased by just 100 pages, or about one-third of its original bulk. The particular specimen before us is marred by the bad sewing which used to characterise nearly all foreign paper-bound books and which we hoped was becoming less common. Well bound in cloth it should make a handy book; the print is clear and the use of black type for headings facilitates reference.

Tests and Studies of the Ocular Muscles. By ERNEST E. MADDOX, M.D. Edin., F.R.C.S. Edin., Ophthalmic Surgeon to the Royal Victoria Hospital, Bournemouth. With 110 illustrations. Second edition. Philadelphia: The Keystone Publishing Company. 1907. Pp. 261.—We welcome the second edition of Dr. Maddox's well-known treatise on the ocular muscles. It is doubtless due to the exigencies of copyright that the book has been published in America. Whilst we regret the necessity it has the compensation of bringing more nearly to the notice of American ophthalmologists a level-headed presentation of the subject which contrasts favourably with the many indigenous productions, some of risk to the life of the mothers and of the children is considerable. We may hope that the new conditions which in the future will attend the clinical teaching of midwifery may render the training which the student receives in the practice of this important subject more nearly on an equality with that which he has received for many years in the subjects of medicine and surgery. Such teaching must include the care of the pregnant woman during her pregnancy and the necessity for a careful investigation of all the conditions which may influence her labour and the safety of herself and her child. No case of pelvic contraction or pelvic obstruction theoretically should be allowed to come into labour with the condition unrecognised and no patient should be allowed to pass through her pregnancy without having been examined, at any rate, by the abdomen and an attempt made to forecast the course of her delivery and to foresee any difficulties which are likely to arise. Such perfection in the practice of midwifery is, we well recognise, almost impossible of attainment, but if we do not aim at a high standard we shall not even attain to a low one. We hope that at any rate one of the chief features in the clinical teaching of midwifery, soon, we trust, to be made compulsory for all students, will be the great importance of the examination of such patients not only when their labour has come on but also some weeks beforehand, so that preventive medicine may be allowed to play a part and the delivery when it does take place may be conducted with the minimum of danger to the mother and the child. At the present time this is not done even in most of the extern lying-in charities attached to our medical schools but we look forward hopefully to the time when it will be considered just as neglectful to allow an expectant mother to run the risks of a labour with a contracted pelvis which has not been recognised because not looked for, as it would be to allow her to run the risk of acquiring some acute infectious disease from the contagion of which no attempt has been made to guard her.

Annotations.

"Ne quid nimis."

THE SALARY OF COUNTY MEDICAL OFFICERS OF HEALTH.

THE Norfolk county council, having decided recently to appoint a county medical officer of health, indulged in a lively debate as to what was a fair remuneration to pay that official. The committee which was appointed by the council to consider and to report on the matter made the recommendation that the salary should be £450 a year, rising by annual increments of £25 to a maximum of £600. Mr. S. Oldman told the council that this decision of the committee was practically unanimous, but the Earl of Kimberley said that his statement was absolutely incorrect and that he himself had fought desperately against it. Mr. Eustace Gurney moved that the salary should commence at £700, rising by annual increments of £25 to a maximum of £850. He pointed out that the new officer would be responsible for the sanitation of 300,000 people and have the supervision of the medical inspection of 55,000 school children. The county wanted a thoroughly experienced and practical man, and such a man would not be attracted by the terms which the council was asked to offer. The motion was strongly opposed by several members from the point of view of safeguarding the ratepayers' interests, although it was pointed out that their best interests would not be safeguarded unless a first-class man were secured for the post. The most interesting contribution that was made to this little squabble was a saying of Mr. Barrett-Lennard who is reported to have remarked that "he had come prepared to move that they paid a lower salary than was recommended. If they wanted a really good man they would have to offer a salary of from £2500 to £5000 a year. He thought a suitable medical officer could be obtained for £350 or £400 a year." Either Mr. Barrett-Lennard has a poor opinion of the chance of finding his ideal sanitarian or else he is more liberal in his views than in his practice in the matter of paying one when he has found him; in either case his argument seems a delightfully innocent *non sequitur*. After a considerable discussion, in which the party in favour of paying liberally fought a losing battle vigorously, it managed to get the committee's recommendation raised by £50. Several speakers alluded to the salaries paid to those officials by the few counties which employ a medical officer of health and it is interesting to compare some of them. Essex pays £1000 and special fees to an officer with charge of a county which includes the teeming district of West Ham and is responsible altogether for 816,500 people. Surrey, with 519,520, pays £800, as do Lancashire with 1,123,850 and the West Riding of Yorkshire with 1,460,860 people respectively, whilst Derbyshire, with 646,000, pays its medical officer £700. Only two county councils pay their medical officers a smaller sum than this last. If we are to compute the salary on a basis of population alone the offer of the Norfolk council seems fairly proportionate; but it must be considered that a county medical officer is a highly trained specialist in his own profession, and in addition has important and responsible administrative functions which recent legislation has made much more arduous, and, moreover, that his emoluments from the post are his only source of earned income. We are therefore in entire accordance with those gentlemen who tried to obtain a liberal remuneration for the new medical officer of a large county. They only lost their motion by 33 votes to 25.

AMALGAMATION OF THE HAMPSTEAD GENERAL HOSPITAL AND THE NORTH-WEST LONDON HOSPITAL.

As is well known to all our readers it has been suggested by King Edward's Hospital Fund that a staff of consulting physicians and surgeons should be appointed for the Hampstead Hospital. This course has been adopted after considerable negotiation, an account of which will be found in our columns, and although there are many circumstances in the situation which impel us to take a contrary view from that of King Edward's Fund we see no way out except that which is being taken by the governing body of the Hampstead Hospital. A further suggestion from the King's Fund of amalgamation between the Hampstead General Hospital and the North-West London Hospital, accompanied by an offer of substantial financial support for the amalgamated institution, has ultimately resulted in the amalgamation being agreed to. As a consequence of these changes vacancies have been declared for two physicians and two surgeons to have charge of the beds in the new building of the Hampstead Hospital. Mr. Edmund Owen, who is already consulting surgeon to the Hampstead Hospital, has consented, in response to a request made to him by the council of the amalgamated hospital, to accept the post of surgeon on the acting staff during the transitional period caused by the change in constitution of the medical staff, and there thus remain three posts to be filled up on the acting staff—two of physician and one of surgeon. The contributory

THE LANCET.

LONDON: SATURDAY, FEBRUARY 15, 1908.

The Children Bill.

PEOPLE of all shades of political opinion can hardly withhold a welcome from the first of the Government Bills for the present session, for it has been framed on lines of common humanity and not of partisanship; indeed, some may think that its utility has been impaired by the omission of all proposals regarding which there is likely to be any serious difference of opinion, but the Government has probably been well advised in doing what it could to insure the Bill an easy passage into the Statute-book. The object of the measure, as lucidly expounded by Mr. HERBERT SAMUEL who moved its first reading on Feb. 10th, is to "consolidate and amend the law relating to the protection of children and young persons, reformatory and industrial schools, and juvenile offenders, and otherwise to amend the law with respect to children and young persons." "Young persons" means those under 16 years of age and "children" those under 14 years. The question of education has, of course, been left for consideration in another measure and that of the admission of children to public-houses will be dealt with in the Licensing Bill. For the rest, the Bill is a notable attempt to codify all the existing Acts relating to child protection and to strengthen them by many new clauses. We do not propose to consider these now in detail but will allude briefly to the chief of them. Perhaps the most welcome are those which seek to exclude children and young persons from the police courts and the common gaols; which suggest the provision of special courts, which shall not be public, to try juvenile offenders; and which propose to prohibit the imprisonment of persons under 16 years of age, with very few special exceptions. It is also proposed to make parents bear the responsibility for rearing young criminals by being made in some instances to pay their fines. A section of the Bill deals with smoking by juveniles, and in accordance with the recommendation of the two committees which have considered the matter prohibits the sale of cigarettes or cigarette papers to persons under 16 years of age and makes it a punishable offence for such children to be caught smoking in the street. How the London policeman is to diagnose the age of the offending child is not suggested but whatever may be the difficulties of administration there is no doubt that it will benefit the whole community, except perhaps the cheap tobacco merchants. The fact that the evils of cigarette-smoking have been exaggerated by many worthy but unscientific folk must never blind us to two things—first, that any considerable amount of smoking is actually very bad for the young; and secondly, that the lad who wants to be perpetually smoking about the streets is modelling his manners upon a bad example and consequently running moral risks. An attempt is to be made to bring the children who are brought up in vagrancy within the reach of the education authorities and to give them some of the ordinary advantages of civilisation. The Act for the Prevention of Cruelty to Children is strengthened and parents are to be made punishable if their children are killed through their carelessness, either by overlying or burning, and we think that the rough and ready distinction thus indicated between accident and criminal negligence is quite a sound one. The penalty is to be light unless drunkenness can be proved.

An important section of the Bill deals with the protection of infant life. In a recent issue[1] we commented on the exemption from inspection under the present law of persons rearing one child only for gain. The Government proposes to appoint a select committee to take evidence on this point and hopes that the House will have received its report by the time when the Bill has reached its later stages. We have for some years given our readers evidence that leaves us in no doubt of the expediency of making compulsory the inspection of all children put out to nurse for a consideration. A smaller matter, but a useful one, is the proposal to legalise the State inspection of all charitable institutions and homes for destitute children. This is as it should be and we hope that in discussing the Bill Members will forget that it is being introduced by a party and thus will help the defenceless children of this country to a charter of their rights and liberties of which any country might be proud.

◆

Rats and Public Health.

AN association was recently formed to wage a war of extermination against rats, and we published at the time an abstract of the sermon of the modern PETER HERMIT, Sir JAMES CRICHTON-BROWNE, when preaching a crusade against a very ancient enemy. The address which he delivered at the meeting held under the chairmanship of Sir LAUDER BRUNTON was fervent and vigorous. He attacked rats as a personal enemy, giving voice to the powerful antipathy against these vermin which has been common to many men in other ages than our own. This dislike of rats, which nowadays appears to have so scientific a basis, depended in the first instance upon selfish and sentimental prejudices. Rats were hated on account of their bodily characters, their evil feeding habits, and their predatory nature; but now the tide of feeling runs high against them because they have been adjudged guilty of harbouring and disseminating the flea which is almost certainly an important means of propagating plague. It is hardly necessary to remind our readers of the case which has been made out against Mus rattus in this evil respect but we will briefly refer to the two chief pieces of evidence which have been recorded in these columns. In the issue of July 27th, 1907, p. 245, we published an abstract of the reports issued by the Advisory Committee appointed by the Secretary of State for India, the Royal Society, and the Lister Institute of Preventive Medicine regarding the causes and control of plague in India. This detailed the very clever and complete series of experiments devised so on, and to the provision of lavatory accommodation, the systematic cleaning of the workshops, and so forth. These special rules were extended in 1898 so as to include a compulsory medical examination once in each month by the certifying factory surgeon and the use of exhaust fans for the removal of dust was enforced. During the last ten years these rules have been in operation and with a most satisfactory result. The medical evidence brought before the Departmental Committee on Compensation for Industrial Diseases showed that fibrosis of the lungs among potters, including china scourers, is now a comparatively uncommon disease and is found only in isolated instances. It was admitted that china scouring was the occupation in which the operative might incur most risk of contracting this disease, but it speaks highly for the present conditions of employment when such a marked diminution in the number of cases of fibrotic lung is so evident. It has been a matter of considerable difficulty for some years past to obtain a typical pathological specimen of fibrosis of the lungs from a potter. The process of china scouring recently has undergone almost a revolutionary change by the introduction of a machine which will entirely dispense with hand labour. The machine consists of a steel cylinder, the interior of which is divided into recesses into which fit skeleton cages containing the ware which has to be scoured. The cages are similar in transverse section to the recesses in the front frame of the cylinder, but they vary in the interior to suit the size and shape of the pieces of ware to be carried in them. Previously to filling the machine with ware a weighed quantity of broken pitchers, ground and screened to a standard size, is placed in the cylinder. When the cylinder is filled it is caused to rotate about 15 revolutions per minute, and in this way the broken pitchers will be carried in a shower between the articles in the various cages and thus the ware will be thoroughly scoured. The fine dust produced in carrying out this procedure is drawn from the interior of the cylinder by an air-current through it which is induced by a centrifugal fan. This method has now been adopted by many of the largest china manufacturers in the country. The advantages of the machine, Dr. Shufflebotham concludes, are: (1) that it scours the ware more effectively than by the revolving brush and gives a smoother surface, and makes it easier to detect bad pieces of ware; (2) that it dispenses with the sand-papering process; (3) that it reduces the number of operatives engaged in this process (who have hitherto scoured with the revolving brush and sand-paper) by one-fourth; (4) that it is a more economical process; and (5) that the worker is not exposed in any way to dust. It may be regarded as an entirely harmless process. It can be applied to all kinds of ware except those of irregular shapes, which would be liable to break in the machine. These articles are best scoured by the sandblast.

---

[1] THE LANCET, Jan. 25th, 1908, p. 244.

THE EXCLUSION OF FAT FROM THE DIET.

PHYSIOLOGICAL considerations would imply that many minor ills of the body would be avoided if only care were taken to include a sufficiency of fat in the diet. Fat, we know, is about the most compact form of fuel which we possess while it exercises a favourable effect upon the processes of the intestinal tract. In excessively cold countries a rich fatty diet is indispensable, for fat is the only food substance which will rapidly replace the heat lost by the body, and travellers in the Arctic regions have related that they could only be kept warm and comfortable by a generous supply of fatty food, in comparison with which the effect of extra clothing was inappreciable. The tendency of to-day in many quarters is to exclude as much as possible the fatty portions of animal foods. Pieces of fat are carefully cut off the slice of ham, mutton, or beef, and only the lean parts are eaten. Indeed, for some unaccountable reason the eating of fat is regarded by not a few as positively vulgar. Such an attitude, of course, displays an ignorance of physiological facts. Cold feet, hands, fingers, ears, and chilblains would in many instances be avoided under a generous diet of fatty food. A digestible fat favours nutrition considerably; it spares much waste of the tissue-forming elements of food. When lean meat alone is given large quantities are required in order that nutrition and waste may balance one another, but if fat be added the demand for flesh is less. Besides, therefore, giving an advantage in regard to making good the repair of the body, the use of fat is economical from the point of view of pounds, shillings, and pence. The absorption of large quantities of fatless meat again tends to overload the blood with nitrogenous waste products. In anæmic persons the partaking of an easily digested fat is commonly followed by the best results, nutrition is greatly improved, and the condition of the blood is often restored to normal. It is well known, again, that easily absorbable fats, such as butter, cream, cod-liver oil, bacon fat, and dripping, are especially valuable to sufferers from wasting diseases. The introduction of the old-fashioned and well-prepared suet pudding into the diet is in perfect accordance with scientific teaching, and from the dietetic point of view, especially in the feeding of young growing people, does probably a really beneficial service to the country. The assumed aversion to fat on the part of a great many people is silly and mischievous, for there can be little doubt that a reasonable proportion of fat in the diet is calculated to preserve the standard of health. Cases of true repugnance or intolerance do of course exist but on the whole they are rare.

THE INACCURATE DOSAGE OF MEDICINES.

THE *National Druggist* (an American journal) for December calls attention to the variation in capacity of ordinary medicine bottles, as shown by a careful examination of one dozen each of two, four, six, and eight-ounce oval bottles of best quality that were purchased on the American market. Each of these 48 bottles, when suitably filled, was found to hold more or less than the correct volume of liquid, the greatest error amounting to 18·3 per cent. of the correct volume. The two-ounce bottles held from 95 to 176 minims more than the reputed volume; in the case of the four-ounce bottles the excess varied from 77 to 190 minims; the six-ounce bottles held from 188 to 366 minims too much liquid; while the eight-ounce size showed a nearer approach to accuracy, ranging from a deficiency of 144 minims to an excess of 134 minims. It is noteworthy that the greatest variations were found in the smaller bottles, in which an error is of more consequence than in the larger sizes. In view of these facts it is evident that the pharmacist should select his prescription bottles with the greatest possible care or else abandon the prevalent custom of regarding the bottle as holding the proper quantity of liquid and filling directly into the bottle. The past three decades have witnessed great advances in the method of preparing and especially of standardising medicines, but this advantage is liable to be rendered nugatory by the failure to divide the ingredients of a prescription into the indicated number of doses. And this is only one of the sources of error incidental to the question of the dosage of medicines. It has often been pointed out in THE LANCET that the capacity of domestic spoons varies within very wide limits. Graduated medicine glasses are relatively seldom employed, with the result that the patient usually takes considerably more or less of the medicine than was intended by the physician. But the public will continue to use the domestic spoon so long as medicines are ordered to be taken the child. Even in different localities in the same country very striking differences in the frequency of the occurrence of such a pelvis may be met with. The statistics of the Rotunda Hospital in Dublin show that on an average 1 per cent. of the women confined at that institution have a contracted pelvis, while in Glasgow it has been computed that one in every ten women suffers from a defect of this kind. Foreign observations show a very wide difference, varying from a frequency of 6 per cent. in Greifswald to one of 22 per cent. in Königsberg. In America WHITRIDGE WILLIAMS computes that every tenth to fourteenth white and third to fifth black woman has an abnormal pelvis. The statistics we have quoted, insufficient though they be, show that this complication of labour is not a very common one in this country, yet it occurs often enough to be met with by every practitioner. It is, however, not the well-marked cases which are difficult to recognise and to treat; it is rather the lesser degrees of contraction, first suspected perhaps towards the end of a prolonged or obstructed labour, which so often lead to disaster. "To be forewarned is to be forearmed" is a maxim which holds with special force in this cause of delayed labour, for such a condition as a general rule can be easily recognised if looked for, and when found is not difficult to treat properly. It is, however, when it is not recognised, and attempts often wrong in principle have been made unsuccessfully to deliver the patient, that so much danger may ensue not only to the life of the mother but also to that of the child. The recognition of a bony deformity of the pelvis sufficient to alter the mechanism of labour or even to cause obstruction during delivery is not a matter of great difficulty to the properly trained practitioner, nor does it entail any unnecessary risk to the patient. A preliminary examination of the abdomen and the careful measurement of the external pelvic diameters, readily carried out without any pain or risk to the woman are usually sufficient to enable a fairly certain diagnosis to be made as to the presence or absence of any marked contraction of the bones of the pelvis. Not only can this be done, when the abdomen is examined, as it always should be about the end of the seventh month of pregnancy, but at the same time the practitioner can determine whether the fœtal head is engaged in the pelvic brim or not, a very valuable guide to the relative proportions of the pelvis and the head. There are, it is true, a few very uncommon causes of pelvic obstruction which cannot be recognised without an internal examination, such as tumours of the pelvic bones or, more important still in view of the great danger which they may cause to both mother and child, ovarian cysts or fibroid tumours in the pelvic cavity.

In a primiparous patient the measurements of the external diameters and the relation of the presenting part, especially when the head is over the pelvic brim, are of the utmost value and importance; this is also the case in a *multipara*, but here there is another important factor to be considered—namely, the obstetric history. It is, however, necessary to remember that this is not always a safe guide, since the degree of difficulty encountered in successive labours in the same patient may be of a very varied character, and especially is this the case in the lesser degrees of pelvic contraction, since it is more particularly in this type of case that a very slight alteration in the position or the shape of the presenting part of the fœtus may make all the difference between a comparatively simple and a difficult delivery. A considerable interest attaches to a review of the various methods which may be adopted in treating these cases not only because of their importance and the often difficult problems which have to be solved but also because such a survey reveals curious and unexpected differences in different countries in the treatment of what would appear to be identical conditions. A good example of this is to be seen in the favour which is extended to the operation of symphysiotomy in France and to a lesser degree in Germany and the disfavour with which this operation is regarded by most English obstetricians. The recent revival of the operation of pubiotomy has led to the publication of a large amount of literature on this branch of obstetric treatment, and it will be very interesting to see whether this operation makes better headway in this country than has the companion operation of symphysiotomy. English teachers of midwifery are accustomed to regard the treatment of cases of pelvic contraction by the induction of premature labour as a very good one, and yet in France this means of overcoming the difficulty meets with but little favour and it is not practised to the same extent in Germany that it is in this country. It is strange that on a matter upon which it might be surmised that there would not be any great difference of opinion the practice in these countries should vary to so large an extent. It is unlikely that obstetricians of different nationalities will ever look at such matters from precisely the same standpoint when even two practitioners of the same nationality may find it difficult to agree upon the same line of treatment. The operation of the induction of premature labour presents, it seems to us, many advantages; it is easy to carry out, entails but little risk to the mother, and if postponed to as late a date as possible in the pregnancy compatible with the delivery of a living child is attended with good results as regards the saving of the life of the child. It has been said that premature children do not grow up and if they do are not healthy, but we know of no well-founded grounds for any such statements. Obviously the mortality of premature children must not be compared with that of full-term children born of healthy mothers, but with that of children born of the same mother after the adoption of the various operative procedures which enter into competition with the induction of premature labour.

The final decision as to the best course to pursue in cases of this kind calls for an exact knowledge so far as it can be obtained of all the factors which have to be taken into account and each case must be judged separately. It is not our purpose to discuss the merits and demerits of the different procedures which may be necessary to effect delivery but rather to call attention to the great necessity for the recognition of this complication of labour and for carrying out an examination of the abdomen in all pregnant women at any rate once during the last two months of the pregnancy. The number of cases of pelvic contraction which are only recognised at the time when the difficulty occurs during the course of the labour must still be very numerous; indeed, we know it to be so, and the consequent reason adduced by M. Moens for publishing his plans in a form accessible to the public at large is said to be to bring about a closer contact of all such persons who value truth above everything and are willing to support all honest endeavours to find truth. Some Royal personages are stated already to have given financial support to this scheme and M. Moens apparently sees no reason for supposing that he will not receive the money for which he appeals. We need hardly say that we have no sympathy with any such work; the truth with regard to the descent of man is not to be proved by experiments of the kind suggested and the proposal to attempt them calls for the strongest condemnation.

INTERNATIONAL LARYNGO-RHINOLOGICAL CONGRESS.

THE first international laryngo-rhinological congress (Türck-Czermak Jubilee) will be held in Vienna from April 21st to 25th under the presidency of Hofrat Professor Dr. O. Chiari. April 22nd will be devoted to six discussions, the subjects of which, together with the names of the speakers introducing them, will be as follows: General Treatment of Local Lesions of the Upper Air Passages, Sir Felix Semon (London); Laryngology and Rhinology from the General Medical Point of View: Instruction and Examinations in those Specialties in Various Countries (Dr. B. Fränkel, Berlin, and Dr. Lermoyez, Paris); Treatment of Tuberculosis of the Upper Air Passages (Dr. Gleitsmann, New York, and Dr. Heryng, Warsaw); Diagnostic and Therapeutic Value of the Roentgen Rays and of Radium in Laryngology and Rhinology (Dr. Burger, Amsterdam, and Dr. Gradenigo, Turin); Connexion between Diseases of the Nose and Naso-pharynx and Diseases of the Eye (Dr. Onodi, Budapest, and Dr. Kuhnt, Königsberg); and International Laryngo-Rhinological Congresses (Dr. Jurasz, Heidelberg). The titles of 57 papers to be read on the following days are announced. The secretary of the Congress is Professor Dr. M. Grossmann, IX. Garnisongasse 10, Vienna.

MEDICAL EDUCATION IN PARIS.

A MOVEMENT for the introduction of "free teaching" (*enseignement libre de la médecine*) in the Paris hospitals has been in progress for about a year under the auspices of the Association d'Enseignement des Hôpitaux, and the inaugural meeting of this association was held on Jan. 19th in the amphitheatre of the Sociétés Savantes. Among those present were a number of important official personages and distinguished representatives of medicine and surgery. M. Lucas-Championnière, the president of the association, opened the proceedings with an address in which he commented on the insufficient utilisation of the teaching resources of the Paris hospitals, whereas in Germany, England, and America strenuous efforts were being made for the improvement of clinical instruction. He then said that the new association did not propose to set up a system of medical education in competition with that of the Paris Faculty of Medicine; its object was merely to extend and to develop the system of hospital teaching which had been in existence for a long time. The objects and methods of the association were fully described in a publication (*livret périodique*) which would be distributed on a considerable scale. The free teaching of the association and the official teaching of the Faculty of Medicine would supplement one another and would form a harmonious system. In conclusion, M. Lucas-Championnière commended M. Roux, M. Bucquoy, and M. Lannelongue, who had given what might be called extra-mural courses of instruction (*cours en dehors de la Faculté*). M. Paul Strauss, a member of the French Senate, said that in 1890, when he was President of the municipal commission of the Assistance Publique, he had endeavoured to bring together in a *libre école* under the patronage of the City of Paris certain hospital physicians and surgeons who were willing to give clinical instruction in their wards. Owing to the hostility of a section of the Faculty of Medicine the project as outlined at that time came to nothing but he anticipated that the present revival of it would be more successful. M. Ambroise Rendu, speaking on behalf of the municipal councillors of Paris, said that they would rejoice to see the medical staff of their hospitals teaching students similarly to the professors of the University. M. Mesureur, director of the Assistance Publique, said that he held views similar to those of the two previous speakers. He did not sympathise with the objections which had been raised against clinical teaching in hospitals and he believed that the patients received better attention when the physician or surgeon had an audience of students.

GREGOR JOHANN MENDEL.

IN a recent issue of the *Pharmaceutical Journal* some interesting particulars are given of Mendel, the discoverer of the law which bears his name. Gregor Johann Mendel was born in 1822 at Heinzendorf bei Odrau in Austrian Silesia. In 1843 he entered as a novice the "Königinkloster," an Augustinian foundation at Altbrünn, and three years later he was ordained priest. From 1851 to 1853 he studied physics and natural science at Vienna, and then, returning to the cloister, he became a teacher in the Realschule at Brünn. In the garden of the cloister he carried out his classic experiments on the edible pea, *Pisum sativum*, and gave the results in the form of a paper which was read to the Brünn Society in 1865 under the title of "Experiments in Plant Hybridisation." An English translation of this paper was subsequently made by the Royal Horticultural Society. In 1869 he published the only other paper which he wrote on natural history, entitled "On Hieracium Hybrids obtained by Artificial Fertilisation." His work appeared at an unfavourable time and both Mendel and the principles of heredity which he enunciated remained unnoticed for 35 years. Mendel was also interested in meteorology and in sun spots. He ultimately became Abbot of Brünn and was greatly liked and respected. He died from Bright's disease in 1884, at the age of 61 years. Further details of the life and work of this interesting priest and man of science are given in "Mendel's Principles of Heredity: A Defence," by W. Bateson (1902), a work which now is probably out of print, and "Mendelism," by R. C. Punnett (1907), published by Macmillan.

LIPOMA OF THE UTERUS.

LIPOMA of the uterus is so rare as to be a pathological curiosity but undoubted instances are on record. Dr. A. G. Ellis, in an interesting paper published in the *Proceedings of the Pathological Society of Philadelphia*, No. 8, 1906, records an example in a woman, aged 60 years, who died in the Philadelphia Hospital from cerebral hæmorrhage, with fatty heart, arterio-sclerosis, chronic endocarditis, and contracted kidneys. The uterus showed a globular swelling occupying the fundus and anterior portion of the body. This tumour was softer than the usual uterine fibroid and was regarded before section as a soft myoma with degenerative changes in its interior. On section, however, it proved to be a mass of yellow fat with a lamellar arrangement like that commonly seen in lipomata. The mass was eight centimetres in its vertical diameter and 6·5 centimetres broad; it was placed interstitially and possessed a thin greyish capsule. On microscopical examination the appearances were characteristic of a lipoma; the fat cells were round or polygonal in outline and were larger than those of normal fat. The blood-vessels were not numerous and the fibrous tissue was only scanty. There was a capsule of fibrous or fibro-fatty character. No muscular tissue was found in the tumour beds, where the treatment can be supervised by any practitioner, will remain in active working, but in other respects the hospital will lose its original cottage hospital character and be managed upon the usual hospital lines. A forcible letter from Dr. Lewis G. Glover, which we printed in our issue of Jan. 18th, p. 186, well expresses what we most all feel at an evolution which appears to divide the medical profession straitly into classes and to minimise the excellent work done by the late staff of local general practitioners. But the unanimity of opinion of the Hampstead medical men was arrived at too late to have its proper effect upon the public and upon the executive of the King's Hospital Fund —a matter which is of considerable regret to ourselves.

LORD LISTER AND THE MARY KINGSLEY MEDAL.

AT a special meeting of the Liverpool School of Tropical Medicine held recently it was resolved to present Lord Lister with the Mary Kingsley Medal which was struck by the school for presentation to distinguished savants and others who have aided the cause of combating disease in the tropics. Special interest attaches to the presentation of this medal to Lord Lister from the fact that his lordship formally opened the Liverpool School of Tropical Medicine on April 21st, 1899. At that time the expenditure of the school was £350 per annum; in the nine years that have elapsed the school has spent on its expeditions and research work alone over £60,000. The medal was forwarded to Lord Lister with the following letter:—

The Rt. Hon. Lord Lister, O.M. 7th February, 1908.

MY LORD,—We have the honour to forward, under separate cover, the Mary Kingsley Memorial Medal on behalf of the Liverpool Incorporated School of Tropical Medicine.

The School much regrets that it has not been possible to arrange for a deputation to wait upon your lordship to present the medal in person.

No words of ours are required to amplify the esteem in which your magnificent achievements are held throughout the world. The Mary Kingsley Memorial Medal has been founded for the purpose of recognising the work of those who have accomplished much in the cause of tropical medicine. No one has accomplished more for this cause, or indeed for the whole cause of medicine, than yourself. The School feels honoured that your lordship has consented to receive the medal.

We remain,

(Sgd.) HELENA, Hon. President.
ALFRED L. JONES, Chairman.
RUBERT BOYCE, Dean.
ALAN MILNE, Secretary.

The following is Lord Lister's reply:—

DEAR MR. MILNE,—I have duly received the Mary Kingsley Medal, with a letter signed by the Hon. President, Chairman, and Dean, and by yourself as Secretary of the Liverpool School of Tropical Medicine.

I beg to return my profound thanks for this highly prized gift and for the exceedingly generous terms in which it is conveyed.

Believe me, very sincerely yours,
(Sgd.) LISTER.

THE FEEBLE-MINDED CRIMINAL.

A PAMPHLET has recently been published by the city of Birmingham education authority containing a number of papers read at a Conference of After-Care Committees which was held in that city last November. One of these papers, dealing with the problem of the feeble-minded criminal, was contributed by Dr. H. B. Donkin who, as one of H.M. Commissioners of Prisons, is able to speak on this question with the combined authority of the physician and the practical administrator. Starting from the fact, painfully familiar to all who have had to do with the work of the special schools for mentally defective children, that the large majority of such children cannot by any system of training be made capable of eventually supporting themselves, Dr. Donkin points out, as a very obvious inference, that a good many of them are likely, following the path of least resistance, to drift into the criminal class. And he states that, as a matter of fact, amongst the prisoners technically known as "convicts"—i.e., those sentenced to penal servitude as distinguished from mere imprisonment, and therefore guilty as a rule of relatively grave offences—a very large proportion are found to be congenitally feeble-minded. To illustrate the hopeless recidivism which characterises individuals of this type when they have once embarked on a criminal career he cites the case of a prisoner who was first convicted when seven years old and who had no less than 28 convictions recorded against him before he had reached the age of 24 years. Amongst the minor offenders who are committed to local prisons the proportion of persons of weak mind cannot be stated positively but Dr. Donkin would put it at from 10 to 15 per cent. at the lowest estimate. The committal of these feeble-minded persons to prison is indefensible but it is also at present inevitable; there is no place other than the prison for the weak-minded law-breaker who cannot be certified "insane." The result is that "feeble-minded prisoners, male or female, oscillate vaguely between the streets, the poorhouse, the asylum, the gaol, and the maternity wards; and the less patently idiotic they are the greater the evils they cause and suffer." In pleading for some more rational way of treating these unfortunate beings in their own interest and in that of society, Dr. Donkin takes occasion to apply a much needed corrective to the pseudo-scientific rubbish about the "born criminal" and the "inheritance of crime" which has done so much to discredit the genuinely scientific study of this social problem. The relation of heredity to crime is, he points out, simply through mental defect. In the case of a weak-minded criminal what may be inherited is not criminality but the incapacity to acquire the elements of good or social conduct; and it is this incapacity to develop the higher and more complex associations, and not any specifically vicious tendency, that makes the imbecile succumb to the temptations of an evil environment. Given better surroundings, a considerable proportion of these defectives would not become criminals at all. It is probable indeed that very many, especially of the higher grade imbeciles, might almost as easily be trained in a harmless as in a harmful direction, though all require continuous regulation and control from outside.

HYGIENIC IMPROVEMENTS IN THE PROCESS OF CHINA SCOURING IN THE POTTERIES.

WE have received an interesting paper from Dr. Frank Shufflebotham of Newcastle-under-Lyme in which he discusses the improvements which from time to time have been introduced in the process known as china scouring and which have been directed towards minimising the dangers to the health of the operatives arising from the inhalation of dust. Hitherto the process has been regarded as one of the most unhealthy branches of the pottery industry but at the present time the conditions under which china scouring is carried out make it, as Dr. Shufflebotham says, a comparatively harmless operation. Scouring consists in removing the roughness from articles of ware occasioned by the adherence of particles of flint used in the saggars in the firing oven. It was originally carried out in primitive fashion by girls who rubbed off the particles of flint with a hard brush or if that was not sufficient the surface was sand-papered. This operation produced clouds of dust which was inhaled by the workgirls, the sharp angular particles causing irritation of the mucous membrane of the smaller bronchial tubes and the pulmonary alveoli, and in quite a short time fibrosis of the lungs might be produced. About 20 years ago a fan was introduced which greatly improved the ventilation of the workshops and at about the same time manufacturers began to scour the ware with brushes. Sand-papering, however, could not be dispensed with as a finishing process. In 1894 the use of a fan was made compulsory by the Home Office and certain regulations were applied in regard to the operatives wearing overalls, head coverings, and

ANNUAL REPORT OF THE REGISTRAR-GENERAL FOR THE YEAR 1906.

I.

WE have pleasure in announcing the appearance within the last few days of the Registrar-General's report on the births, deaths, and marriages in England and Wales for the year 1906. Of the annual reports issued from Somerset House since the assumption of office by the present Registrar-General this is the sixth, and from the rapid survey of it which has hitherto been practicable we believe it to be a worthy addition to a series of essays on vital statistics hitherto unrivalled in any language.

In his first report—namely, that for the year 1901—Sir William Dunbar availed himself of the opportunity afforded by the opening of a new century to arrange, and where necessary to modify, the information contained in previous reports so as to comply with modern requirements, whilst still retaining the means of comparison with data contained in the long list of annual volumes issued by his predecessors. For example, the method initiated by Major Graham was resorted to—namely, that of presenting those portions of the report which treat of mortality and its causes in the form of a letter for which his medical adviser is responsible. The reasons for this course are indicated in Sir William Dunbar's first report, wherein, after graceful acknowledgment of the coöperation of medical men as the indispensable factor in the construction of vital statistics, he expresses the hope that our profession will view with approval an arrangement by which the information which they contribute gratuitously will in future be analysed and its significance indicated by the medical member of his staff. It is obvious, however, that reports of this nature possess a vital interest for the general public; and therefore the Registrar-General, in his introductory remarks, properly and very usefully summarises, for the benefit of his non-medical readers, the more technical portion of Dr. Tatham's letter, and this he does with discretion and without unnecessary detail.

In noticing the successive reports of the Registrar-General since his assumption of office we have commented on the steady expansion of their scope from time to time. In the report before us, for example, we observe that under the head of "international statistics" the data formerly published for the principal European countries other than our own have been extended so as to include particulars relating to general mortality, to the loss of life caused by the principal epidemic diseases, and to the fatality of pulmonary tuberculosis and of cancer. Accordingly, comparison is now practicable between the mortality from these diseases in our own country and that of countries beyond the sea. In like manner the mortality of infants in our Australasian colonies and in some foreign lands may by this means be contrasted with that obtaining at home. A new feature in these reports is the appearance in the present issue of a series of well-designed diagrams illustrative of changes in the English rates of marriages, births, and deaths, the facts presented being carried back to the earliest periods for which trustworthy statistics are available. Many persons there are to whom graphic representations of statistics appeal more strongly than would any tabular arrangement of figures, which latter are sometimes passed over as too complicated for interpretation by any but expert readers. To such persons we commend for attentive study the excellent series of diagrams in this report.

As might have been expected, the subject of infantile mortality which has been brought into prominence by the National Conference recently held in London is commented upon somewhat fully in the present report. Referring to the generally accepted statement, which until now has passed unchallenged, that whilst the mortality among adults has fallen steadily in recent years there has been no corresponding fall in infantile mortality, the Registrar-General assures us that this statement holds good only up to the close of the nineteenth century. For since the beginning of the current century there has been a break in the growth of infantile mortality which, with some fluctuations, he acknowledges to have prevailed throughout the previous decennium. Among infants in their first year of life the average mortality has shown a decrease since 1900 amounting to 11 per cent. on the rate of 1891–1900. He points out the important fact that about one-third of the total deaths at this early age are due to ante-natal influences, such as premature birth, atrophy, debility, and congenital malformations, a group of conditions that may be described under the general heading of "immaturity." Over and above these conditions he holds that the employment of women in textile and other industries, ignorance, careless and insufficient nursing on the part of mothers, and overcrowding and insanitary environments are important factors in bringing about a high rate of infantile mortality. Passing reference is made to the Act for the notification of births which was passed in the last session of Parliament and the Registrar-General expresses the opinion that, if consistently carried out, a well-devised system of early notification of births, worked in connexion with the present registration system on the one hand, and with sanitary administration on the other, will serve as a most effective and lasting barrier with which to stem the tide of infant mortality.

A prominent feature noticeable in this connexion is the evidence contained in the report of the pains taken by its author to present the information at his disposal in such a way as to avoid statistical fallacy, and this, in a highly technical matter like the present, is an object by no means easy of attainment. For example, in his remarks respecting the recent improvement in infantile mortality, Sir William Dunbar, after recounting the various conditions probably conducing to this favourable result, cautions his readers thus: "At the same time," he says, "I think it right to refer to the special influence of summer temperature and rainfall upon infantile mortality. For instance, the showery and exceedingly cool weather experienced in the past summer checked the rise in the rate of infant mortality that usually occurs in the third quarter of the year. ...... It should accordingly be borne in mind that, speaking generally, throughout the last six years this country has experienced a cycle of favourable seasons and that for this reason before calculating upon a continuation of the present fall in infantile mortality it will be prudent to await a return of hot and dry summers in order that the extent may be ascertained to which existing sanitary arrangements in some of the manufacturing centres are able to withstand the onset of extreme heat and dryness without involving the inordinate sacrifice of infant life."

In the history of English vital statistics nothing stands out more prominently than does the unequal incidence of mortality among the infant section of the community. In illustration of this fact a chart is presented showing the distribution of infant mortality in the several registration areas. The chart shows that with slight fluctuation these areas show severally either a high or a low mortality through a long series of years. From a table contrasting the present with the past we learn that as compared with 30 years ago all the English counties except Essex and Monmouthshire have shown in recent years a considerable fall in mortality. On the other hand, of the 12 Welsh counties no fewer than nine show an increase of infant mortality during the last 30 years.

It has frequently been remarked in these reports that those areas of the country which comprise the districts of the mining, textile, and pottery industries show very badly in respect of infant mortality; not only are the rates excessive in many of the larger towns of these districts, but they are equally so in the majority of the smaller towns. In proof of this a table is inserted showing that there are several groups of towns in close contiguity in Staffordshire, Cheshire, Lancashire, and Glamorganshire carrying on industries of one or another of the kinds here spoken of, in no fewer than eight of which towns an average of about one in every five children born did not survive the first year of life. The towns alluded to are Bilston, Longton, Tunstall, Stalybridge, Burnley, Farnworth, Ince-in-Makerfield, and Aberdare. Speaking generally, excessive waste of infant life is associated with a high birth-rate and with overcrowding, and it is probable that these conditions prevail more or less in the majority of the towns now specified. It should be observed, however, that there exist several towns which have a comparatively low birth-rate and little overcrowding, but in which, nevertheless, infant mortality is very high. Such towns not only produce feeble children but lose an immoderate proportion of those produced. The towns with low rates of infantile mortality may generally be described as superior residential towns or suburbs, the birth-rates in which by spoonfuls. The difficulty could be met by the adoption of the following simple plan. In writing prescriptions let the doses be given in drachms, half ounces, and ounces. The patient, being ignorant of the equivalent in spoonfuls, would then be obliged to procure a proper measure. At present the situation is "Gilbertian." A correct diagnosis and a nicely balanced prescription, dispensed from the purest drugs standardised to a high degree of accuracy, are muddled, or possibly rendered useless or dangerous, by the use of inaccurate medicine bottles and still more inaccurate domestic spoons.

THE STATUE OF SIR THOMAS BROWNE AT NORWICH.

IN the year 1903 the corporation of the city of Norwich informed the committee of the Sir Thomas Browne Memorial that the corporation would provide a site for the statue of Sir Thomas Browne in the garden which has just been laid out in the Haymarket. The statue was accordingly provided by the subscribers at a cost of upwards of £1000 and was unveiled on Oct. 19th, 1905, by Lord Avebury. Recently the corporation of Norwich proposed to place lavatories and urinals behind, and in close proximity to, the statue and it is felt by many in Norwich that the collocation of the statue and the urinals is, to say the least of it, unsatisfactory. A memorial has therefore been drawn up, which has been largely signed by medical men and others both in Norwich and in London, praying the corporation not to proceed with the scheme for erecting the lavatories and urinals on the site allotted to the statue. We earnestly hope that the corporation will accede to the prayer of the memorialists and will find some other and more appropriate site for the proposed lavatories.

LUMBAR PUNCTURE IN THE MENINGEAL FORMS OF ENTERIC FEVER IN CHILDREN.

IN the *Gazette Hebdomadaire des Sciences Médicales de Bordeaux* of Jan. 26th Dr. Ch. Rocaz and Dr. Firmin Carles have published an important paper on the therapeutic value of lumbar puncture in the meningeal forms of enteric fever in children. In children enteric fever is often complicated by meningeal symptoms. In some cases these are slight and fugitive and of only secondary importance; in others they are more marked and persistent and occupy the first place among the clinical manifestations. For a long time writers discussed these meningeal symptoms and insisted on the variability of the prognosis according as there existed true meningitis or meningeal symptoms without an anatomical substratum (meningism). The introduction of lumbar puncture has given a new interest to the question. From the clinical standpoint four types of meningeal manifestations in enteric fever in children may be distinguished. In the first, towards the end of the second week appear intense headache, repeated vomiting, and constipation (which may replace the pre-existing diarrhœa). Cutaneous hyperæsthesia, irregularity of pulse and respiration, various vaso-motor troubles, and retraction of the head follow. Ocular symptoms (inequality of pupils, strabismus, and ptosis) are rarer and of more serious prognosis. After some days these symptoms may disappear but sometimes they terminate in death. In the second type the complete "*tableau*" of acute cerebro-spinal meningitis is presented. In addition to the symptoms described Kernig's sign appears and rigidity of the neck and spine, as marked as in acute cerebro-spinal meningitis, follows. The rigidity may extend to the limbs and the hands and feet may assume the attitude of tetanus. This is one of the most frequent types. The third type is rarer. The attack presents from the first the complete "*tableau*" of tuberculous meningitis and erroneous diagnosis is easy. The fourth type is peculiar to infants. During an attack of enteric fever convulsions appear and lead to a rapidly fatal termination. Lumbar puncture has thrown a new light on the pathogenesis of these phenomena. It may yield (1) pus in which may be found the typhoid bacillus in pure culture, other microbes, such as staphylococci, or a mixture of the typhoid bacillus and other microbes; (2) a turbid or transparent liquid in which centrifugalisation shows microbes—the typhoid bacillus or others; (3) a liquid which, though quite clear, contains abnormal cellular elements, usually abundant lymphocytes; and (4) a liquid of normal composition but flowing out in a jet, indicating abnormally high tension. In the first two cases the pathogenesis of the meningeal symptoms is manifest; the meninges are infected. In the third case it is logical to suppose that the meninges are irritated by microbial toxins which give to the cerebro-spinal fluid its cytological characters. In the fourth case also the hypersecretion of cerebro-spinal fluid is probably due to the same cause. M. Roger has shown the frequency of serous exudations under the action of various toxins. These facts also explain why lumbar puncture can be useful in the meningeal forms of enteric fever. Concetti, Netter, and many others have shown that repeated lumbar puncture is the best treatment of bacterial meningitis. The operation is therefore indicated in cases of enteric fever in which the cerebro-spinal fluid contains microbes. Each puncture removes some of the microbes and they are reproduced with difficulty as the cerebro-spinal fluid is a bad culture medium. They therefore soon disappear. If, on the other hand, the meningitis is simply toxic, the removal of a certain quantity of fluid charged with toxins cannot fail to have a favourable action. In the case of abnormally high tension puncture diminishes the pressure on the nervous centres and removes the resulting symptoms. The following is one of eight cases showing the value of lumbar puncture related by Dr. Rocaz and Dr. Carles. A boy, aged eight years, had a severe attack of enteric fever characterised by profuse diarrhœa, a temperature of 103·6° F., rose spots, and so on. On the eighteenth day he complained much of headache, cerebral vomiting occurred, and the diarrhœa was replaced by constipation. The head was retracted, the neck was rigid, and Kernig's sign was present. Lumbar puncture yielded 12 cubic centimetres of clear fluid under high pressure. Cytological examination showed that this was of normal composition. All the symptoms of meningitis had disappeared on the following day and uninterrupted recovery followed.

AN EXTRAORDINARY PROPOSAL.

WE have received a copy of an extraordinary work entitled, "Truth: Experimental Researches about the Descent of Man." The author of this remarkable book is M. H. M. Bernelot Moens and we regret to see that he is to be assisted in his enterprise by Dr. H. M. J. Boshouwers, a medical man. The book, or pamphlet, is intended, we suppose, as a preliminary notice, and an appeal for pecuniary assistance in the prosecution of the work which these gentlemen intend to carry out in the Congo. Their aim is to furnish experimental proof of the view that man is a highly developed anthropoid ape, and for this purpose they intend to practise artificial fecundation of the females of the anthropoid ape with the sperm of man; the gorilla and chimpanzee to be fecundated with negro semen. M. Moens also wishes to carry out experiments in the crossing of the anthropoid apes either by artificial or natural fecundation and to study human diseases, more especially syphilis, by means of experiments on these animals. The book is to be printed in Dutch, French, and German, and the and was examined by Sir Thomas Stevenson and Dr. French. At this second examination also the plaintiff was present. No trace of poison was discovered. The organs were found replaced in the usual manner in the cavity of the chest, with the exception of the brain which had no doubt disintegrated during the interval which had elapsed since the first post-mortem examination. The version of this not unnatural circumstance which was printed in the *Star* was as follows :—

> POISON DRAMA.
>
> *The Exhumation of Mrs. Blume's Body.*
>
> It is reported that the exhumation of the body of Mrs. Blume of Maxwell-road, Fulham, which took place at Brompton Cemetery a fortnight back, has proved abortive so far as the discovery of any trace of poison is concerned. Sir Thomas Stevenson and his assistant were unable to make any examination of the organs, in which alone traces of poison, supposing it is present in the body, could ordinarily be detected. Some parts of the organs which it is now desired to examine are, in fact, reported to be missing. It should be explained, however, that this circumstance does not reflect upon any person now concerned in the case, but may be a consequence of the first post-mortem examination which was made at the time of the old lady's death.

This involved so serious an imputation upon the plaintiff's conduct in connexion with the post-mortem examination, for which he alone was responsible, that he was compelled to bring an action to vindicate his character, when he was met not only with the defence that the words were not capable of the defamatory meaning which was assigned to them and were fair comment, but also that they were true in substance and in fact, this latter plea was aggravated, as the judge pointed out at the conclusion of the case, by the placing upon the record of "particulars of justification," including a list of portions of the body alleged to be missing in consequence of the plaintiff's conduct. It is not surprising that in these circumstances it was felt desirable by the legal advisers of the defendant newspaper to settle the case by means of a substantial payment. A jury could hardly have failed to award heavy damages considering that the evidence of Sir Thomas Stevenson was that the whole of the remains had been found by him except the brain; that the placing of it in the cavity of the chest with the rest of the parts removed for examination was proper and usual; and that the disintegration which had apparently taken place had not affected the result of the necropsy, which had not led to the discovery of any trace of poisoning. In addition the plaintiff had given evidence that his practice had been injured by the publication of the libel. The statement and the suggestion made when once shown to be erroneous would, indeed, have been very difficult to excuse and the *Star* could hardly have urged in its own defence an attitude sympathetic as a general rule towards medical science or medical men. The effect of its misstatement, moreover, was likely to extend beyond the individual medical practitioner whose successful vindication of his character is a matter for personal congratulation and who would naturally find among his poorer patients many readers of a halfpenny evening newspaper. The result of the paragraph quoted above might well be to increase the dislike and distrust evinced by many for the holding of post-mortem examinations upon the bodies of their relatives. This feeling of aversion is a natural one and it is highly undesirable that it should be increased by any suggestion that after post-mortem examination the body in question will not receive complete sepulture like any other.

POST-GRADUATE MEDICAL STUDY ABROAD.—The French Association for Post-graduate Medical Study, which is known as the "E.M.I.," asks us to state that it is organising a tour of inspection of the medical and sanitary institutions of Italy from April 12th to 28th. The places to be visited include Turin, Milan, Padua, Venice, Bologna, Florence, Rome, Naples, Pisa, Genoa, and San Remo. The organisation of the tour has been entrusted to Professor Pini, the corresponding member of the association in Italy, and he has the coöperation of the most eminent leaders of the medical profession in that country, including Baccelli, Bossi, Bozzolo, Cozzolino, De Giovanni, Mangiagalli, Marlimuni, Mya, Pinzani, Vitali, and Zeri. The complete programme of the tour has been published in the January number of the journal "L'E M.I.," the official organ of the association, and can be obtained, together with any other information that may be required, by sending a stamped addressed envelope to the secretary at the headquarters of the association, 8, rue Francois-Millet, Paris.

Looking Back.

FROM

THE LANCET, *SATURDAY*, Feb. 13th, 1830.

CONSUMPTION OF NUX-VOMICA AND COCCULUS-INDICUS.

To the Editor of THE LANCET.

SIR,—Although I am no professional man, I have been a subscriber to THE LANCET from its very birth, and am fully aware how useful it has been in exposing delusion, fraud, and humbug. You have *occasionally* touched upon the sophistication or adulteration of what is taken into our stomachs as nutriment. I do not believe all that the author of "death in the pot" advances, but the subject is an important one, and merits the most serious attention.

By a return made officially from the Custom-house to the House of Commons in the last session, and from other authentic documents in my possession, it appears, that, upon an average of some years there has been an annual *importation* into Great Britain of

	lbs.
Nux-vomica	30,000.
Cocculus-indicus	12,000.

Now, Sir, I wish to ask of your medical and chemical readers, or wholesale druggists, what becomes of this enormous quantity of poison; a trifling quantity is employed in medicine, and for the destruction of vermin, and by poachers we know that a comparatively small quantity of these articles is also used; but if there be any other open, honest, or avowed purpose to which they are applied in any part of the world, it would remove some very unpleasant *suspicions*, and be very gratifying to many persons to be made acquainted with it.

I am, Sir,
Your most humble servant,
J. H. G.

Bath, February, 1830.[1]

---

[1] The above letter (written 78 years ago) evidently refers to the adulteration of beer, but happily, owing to the provisions of the Adulteration of Food and Drugs Acts following on the labours of the Founder of THE LANCET by his Analytical Sanitary Commission (commenced in the year 1851) and his personal inquiries, this adulteration is a thing of the past.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 9240 births and 5692 deaths were registered during the week ending Feb. 8th. The mean annual rate of mortality in these towns, which had been equal to 20·0, 18·5, and 18·2 per 1000 in the three preceding weeks, increased slightly to 18·3 in the week under notice. During the first six weeks of the current quarter the annual death-rate in these towns averaged 18·5 per 1000; the rate in London during the same period did not exceed 18·0. The lowest annual death-rates in the 76 towns last week were 6·2 in Hornsey, 9 9 in Leyton and in Willesden, and 10·3 in York; the rates in the other towns ranged upwards to 25·3 in Liverpool, 27·0 in Merthyr Tydfil and in Birkenhead, and 29·8 in Grimsby. The rate in London last week did not exceed 17·7. The 5692 deaths registered in the 76 towns during the week under notice showed an increase of but 11 upon the number in the previous week, and included 447 which were referred to the principal epidemic diseases, against 409 and 441 in the two previous weeks; of these, 192 resulted from whooping-cough, 73 from diphtheria, 71 from measles, 48 from diarrhœa, 39 from scarlet fever, 24 from "fever" (principally enteric), but not one from small-pox. The deaths from these epidemic diseases in the 76 towns were equal to an annual rate of 1·4 per 1000, the rate from the same diseases in London being 1·3. No death from any of these epidemic diseases was registered last week in Blackburn, Walthamstow, Leyton, Hornsey, Coventry, or King's Norton; the annual death-rates from these diseases in the other towns ranged upwards, however, to 3·0 in Burnley and in Birkenhead, 3·6 in South Shields, 3·7 in Warrington, and 5·4 in Salford. The fatal cases of whooping-cough in the 76 towns, which appeared to be a pure lipoma. Tumours of the uterus are extremely common. Gurlt in an analysis of 13,971 tumours observed at the hospitals of Vienna found that 4115, or 29 per cent., originated in the uterus. Williams found an almost identical percentage—viz., 23·7 in 13,824 cases of tumours treated in four large London hospitals, but no example of lipoma is included. Seydel in 1903 found a lipofibromyoma of the size of a walnut in the uterus of a woman, aged 58 years, and after an exhaustive study of the literature could only find ten other cases of fatty tumour of the uterus. There were thus on record at this time four cases of lipoma, two of lipomyoma, and four of lipofibromyoma, the remaining case being described simply as composed of adipose tissue. In addition, there are three other cases in the literature of this subject which were macroscopically of fatty appearance but were not examined microscopically and were on this account excluded by Seydel. Dr. Ellis has studied the published accounts of these various cases and gives brief accounts of them. Apart from his own case he has been able to find no further instances. The ages of the patients in the 12 cases varied from 28 to 68 years. Several of the women were sterile, while one had 13 normal labours and three miscarriages. The histogenesis of these tumours is a point of some interest, since the normal uterus does not contain adipose tissue. It has been suggested that they arise by the muscle cells changing into fat cells but there is no evidence in support of such a metaplasia. The usual view is that they originate in rudiments of embryonic fat included in the uterus and their occurrence is taken as supporting Cohnheim's view of the genesis of tumours.

VENEREAL DISEASE IN RANGOON.

THE reports that have recently reached us concerning the prevalence of venereal disease in Rangoon are *distressing*. In the words of one of the officials of the municipal committee, "since the suspension of the C.D. Acts in India and Burma by orders from home we have now come to a pass which is truly intolerable." The *statistics* that have been collected substantiate this assertion. Major C. E. Williams, I.M.S., the able health officer of the Rangoon municipality, instituted an inquiry at the instance of the committee to ascertain the extent to which venereal diseases were prevalent in Rangoon, the scope of which inquiry was limited to three points—namely, (*a*) the extent to which venereal diseases are prevalent in Rangoon at the present time, (*b*) a comparison of the figures for admission for these diseases at certain military and civil hospitals during the past ten years, and (*c*) a comparison of the data obtained under the last point with those on record for other cities and cantonments in India and Burma. The sources of information on these points were the experience of medical men practising in Rangoon, the medical records of the Rangoon garrison as shown in the annual sanitary reports published by the Government of India, and the tables appended to the annual sanitary reports of the Sanitary Commissioner with the Government of India and Inspector-General of Civil Hospitals, Burma, for the years 1895–1905. As a result of this inquiry it was ascertained that in the opinion of the majority of the medical practitioners in Rangoon, including all those who can claim to have an intimate and extended acquaintance with the people of this town, venereal diseases were more prevalent at the present time than formerly, that they are found in all classes of the population, and that they assume a very virulent type. Further, that youths of all classes are especially prone to contract the diseases, and that innocent women and children suffer from the results of direct and inherited infection, whilst the infant mortality is increased from this cause. The statistics of the military and civil hospitals in Burma, the health officer concludes, are open to criticism and do not throw much light on the problem; they indicate these diseases to be more prevalent in Rangoon than in Calcutta and other Presidency towns, but that their prevalence on the whole tends to decrease. But the health officer considers the testimony of the medical men of the town to be the more valuable in forming a correct estimate of the prevalence of venereal diseases, the military returns referring to only a small section of the population living under special conditions, whilst those of the civil hospitals rest upon varying and uncertain elements of the population. 19 years ago all restrictions upon prostitution and the propagation of venereal diseases were withdrawn, this being due to the interference of the Home Government. Compulsory attendance at the Lock Hospital in Rangoon ceased in August, 1888. Since that time infected women have been allowed to go on with their disease-spreading trade.

ANTI-SWEATING DEMONSTRATION.

ON Tuesday evening, Jan. 28th, a meeting was held in Queen's Hall to demonstrate against the evils of what is known as the sweated industries system. The meeting took place under the auspices of the National Anti-Sweating League, was very largely attended, and was presided over by the Bishop of Birmingham. *A proposition to the following* effect was introduced by Mr. Arthur Henderson, M.P., the newly made leader of the Labour Party in Parliament:—

> That this representative national demonstration calls the attention of His Majesty's Government to the evils arising from the gross underpayment of workers proved to exist in particular trades, and requests that Wages Boards on the lines of those suggested in the Sweated Industries Bill of Mr. Arthur Henderson be established in such trades.

This motion was seconded and supported by Sir Charles W. Dilke, M.P., Father Bernard Vaughan, Miss Mary R. MacArthur, and Mr. G. Bernard Shaw. All the speakers dwelt upon the insanitary conditions under which the majority of those engaged in sweated industries live, conditions which act especially as regards women home-workers, and have a serious effect upon infant mortality and may also influence race deterioration. The Bishop of Birmingham in his speech alluded to an interesting point, that by the Mosaic law both the material and sanitary welfare of workers was carefully guarded, and that throughout the Bible the necessity of giving a living wage to all who toiled with their hands was emphasised.

THE Central Hospital Council for London has issued the report of its committee appointed last July to advise whether the constituent hospitals of the council, which represents all the larger hospitals, should take joint action to insure the purity of their milk supply. The committee recommends joint action and indicates to the hospitals the requisitions which it considers should be made binding upon those who contract to supply the hospitals with milk. The report will receive detailed notice from us—it is a highly important document.

THE Department of Public Health of Queensland in a bulletin dated Jan. 4th states that for the week ending Jan. 4th a fatal case of bubonic plague occurred at Brisbane on Jan. 3rd. The patient, a man, aged 53 years, living at Boundary-street, Spring Hill, and working on a coal hulk in the river, was admitted to the Brisbane General Hospital on Jan. 1st. The post-mortem examination of the viscera of the body showed that death was due to plague. This is Case 1 of the current year.

THE 135th anniversary dinner of the Medical Society of London will take place at the Whitehall Rooms, Hotel Métropole, on Wednesday, March 11th, at 7.30 P.M. Dr. J. Kingston Fowler, President of the society, will occupy the chair.

TERRITORIAL FORCE.

In a printed reply circulated with Parliamentary papers on Feb. 7th, Mr. Haldane has informed Mr. Crooks that, as has already been announced in THE LANCET of Dec. 14th, 1907, p. 1718, it is proposed to appoint Surgeon-Lieutenant-Colonel (Hon. Surgeon-Colonel) P. B. Giles one of the medical officers of the 1st Herefordshire Rifle Volunteers, to the office of principal medical officer of one of the London divisions of the Territorial Force. He is (adds Mr. Haldane) commandant of the Volunteer Ambulance School in London, an institution which has been most successful in training a large proportion of the Volunteer medical officers. He resides near London. Seniority was not the determining factor in selecting officers for the appointments, but those officers best fitted to carry out the work were chosen, seniority being given its due weight.

DEATHS IN THE SERVICES.

Inspector-General of Hospitals and Fleets Sir John Denis Macdonald, K.C.B., F.R.S., R.N., on Feb. 7th, at Southall, aged 82 years. He entered the service as surgeon in 1849, was promoted to staff-surgeon in 1859, to fleet-surgeon in 1866, to deputy-inspector-general in 1875, to inspector-General in 1880, and retired six years later.

Surgeon-General William Henry Rean, Indian Army (retired), on Feb. 6th, aged 81 years. He entered the East India Company's service in 1853, and in 1857 served with the Madras Fusiliers in the attempted relief of Cawnpore. After the massacre he was appointed chief medical officer in charge of the standing hospital at Cawnpore, where he contracted cholera. After serving as deputy-surgeon-general at Kampti he retired in 1881.

The *Times* states that about 100 boys belonging to the training ship *Impregnable* at Devonport are in hospital, the majority suffering from influenza which is very prevalent throughout the port.

A Royal Naval hospital is to be opened at Queensferry with a staff of one fleet-surgeon or staff-surgeon, one surgeon, one chief sick-berth steward, and two sick-berth attendants.

Correspondence.

"Audi alteram partem."

HOSPITAL ALMONERS.

To the Editor of THE LANCET.

SIR,—In view of the letters of appeal from general practitioners and others that appear constantly in the daily papers against the deplorable abuse of the out-patients' departments of our London and provincial hospitals, I venture to call the attention of your readers to a system which is slowly but surely gaining ground among the hospitals of this vast metropolis. The fact that the out-patients' departments are not only centres of startling abuse but also the means of pauperising a large proportion of the working classes has been brought before the public from time to time for the last 30 years.

About 12 years ago the Royal Free Hospital, recognising the responsibility incurred in this respect, created the post of almoner. A lady, duly qualified by experience and knowledge and being intimately acquainted with the mode of living and ways of thought obtaining amongst our poorer classes, was appointed to the post. Her duties were: 1. To interview all new patients to the hospital after such patients had been seen by a member of the staff and to investigate thoroughly each case by means of outside visitors and societies. 2. To report to the authorities all cases which were not suitable for free medical treatment. 3. To provide from the funds of the Hospital Samaritan Fund, in coöperation with outside charities, all surgical instruments, convalescence, &c., recommended by the medical staff except in such cases where the patients or their family were able to provide such instruments and treatment themselves. 4. To ensure that the home conditions of the patients should, so far as possible, be suitable, and that the directions of the physicians or surgeons as to diet, fresh air, exercise, or rest should be carried out.

It was not long before the system I have briefly sketched recommended itself to the authorities of other hospitals and after two or three years Westminster and St. George's Hospitals created similar posts and to-day there are no less than nine well-known hospitals where almoners are working. The system leads to economy both in the time of the staff and the expenses of the hospital and its satisfactory results may be attested by the fact that *no hospital that has appointed an almoner has ever seen reason to recall its decision.* The system must of necessity appeal to any hospital with a medical school in that it protects the interests of the general practitioners who have been, or are being, trained within its walls. As no patient is dismissed without the consent of the physician or surgeon who has examined the patient it will be easily seen that the interests of the medical school as to clinical material are guarded.

The daily letters of thanks and approval from outside doctors show that the general practitioners realise that a very potent method has at last been set on foot to safeguard their interests. The work of an almoner is both difficult and arduous and calls for a very special training and careful selection of candidates. A hospital almoners' council has lately been formed for the purpose of arranging the training and selection of almoners and for providing suitable candidates for London and the provinces.

It is in the hope that this letter may explain briefly the work of an almoner and thereby prove that the out-patients' departments need no longer be a cause of apprehension to the outside doctors or a centre of pauperisation and abuse that I have ventured to encroach upon your valuable space. May I add that I shall be pleased to give any further information on the subject either by letter or by appointment to any of your readers who may be interested in the question.

I am, Sir, yours faithfully,
A. S. MORSE, Capt. and Sec.

Hospital Almoners' Council, Denison House, Vauxhall Bridge-road, S.W., Feb. 11th, 1908.

PLEURAL EFFUSION AND ITS TREATMENT.

To the Editor of THE LANCET.

SIR,—Dr. Harry Campbell tries, but in vain, to make the worse appear the better cause, and I should think he would make a very obstinate juryman whom the other 11 might have some difficulty in convincing. I can therefore scarcely hope to convert him from the error of his ways, so I shall not trouble much about this lost sheep, but I shall try and show the ninety and nine, who have not gone astray, the utter worthlessness of his facile pen. I shall now analyse his letter paragraph by paragraph.

First.—His little pleasantries do not trouble me much and do not cover his retreat from an untenable position in citing a condition which does not exist. He knows as well as I do that Dr. Harry Campbell is not the man to make "concessions for the purpose of humouring Sir James Barr," or anyone else. There is a very considerable difference between an adherent and a non-adherent pleura which cannot be glossed over by saying that "they did not affect one way or the other the main issue between us." The elasticity and tautness of the lung are thus readily affected, and I cannot allow Dr. Campbell to shift his position at his own convenience without exposing his retreat to my merciless flank fire. In my first letter I agreed that the elasticity and tautness of a substance are two quite different things, but the continuous tautness of the lungs depends on their elasticity and the pressure of air within them. I say so still.

Second.—In the first 12 lines he gives his whole show away and practically accepts my contention, but his illustrations are not very happy. "It is not the elasticity of the traces attached to a wagon which causes the wagon to be pulled along." Neither is it the *tautness* of the traces, nor the *tautness* of the lungs which exerts the traction, but the force that causes and maintains the *tautness*. If the stress or force applied to a series of loosely connected wagons be intermittent they bump against one another, but if they be braced up and have an elastic connexion through their buffers all this bumping disappears. The elastic lungs are held against the thoracic parietes by the atmospheric pressure within the lungs, a pressure amounting to about 760 millimetres of mercury, less, under ordinary circumstances, a few millimetres of mercury due to the elasticity of the lungs and the variations in the intrapulmonary pressure during the different phases of respiration. The greatest possible fall in the intrapulmonary pressure, as in Müller's experiment, could not are conspicuously low, and there is no evidence of overcrowding. Among places of this sort there are two which deserve special mention—namely, Swindon and Burton-on-Trent, for the statistics of both these towns clearly prove that industrial urban conditions need not of necessity be inimical to infant life.

In England at the present day there are numerous areas, urban as well as rural, where the rates are low and compare favourably with the lowest rates in the several foreign and colonial states. On the other hand, there remain many industrial centres where excessive rates indicate that the conservation of infant life is much neglected. Sir William Dunbar closes his remarks on this important topic with the following weighty words:—

> It may confidently be affirmed that in future any permanent reduction in the mortality of young children in England and Wales, as a whole, will largely depend upon a due recognition of parental responsibility, on the one hand, and, on the other, an improved health administration in these industrial areas, particularly in that of numerous small towns.

Closely associated with the foregoing subject, this report contains important information respecting the waning fertility of English mothers. The birth-rate in England and Wales attained the highest point on record in the year 1876, and the mean rate of birth in the quinquennium following that year has been taken as a standard for comparison. Based on the proportion of births to the number of possible mothers, married as well as single—i.e., on the total number of women living at child-bearing ages—the fall since that period has amounted to more than 29 per cent., whilst the fertility of married women, based on the ratio of legitimate births to wives of conceptive ages, showed a decrease amounting to 25 per cent. within the same period. In other words, if the fertility of married women in proportion to their numbers had been identical in 1876–80 and in 1906 the legitimate births in 1906 would have exceeded by more than 300,000 the number actually registered in that year.

The Registrar-General has more than once admitted in his reports that the registers of birth as well as of death are capable of improvement, and in the present report he reverts to the subject. He finds, however, on consideration that further evidence is required of the desirability of including some possible improvements before embarking on the reconstructing of the registers for a total of more than 2000 districts. As the existing registers give no information respecting the ages of mothers there are no means of ascertaining the fertility of women at the several ages comprised in the child-bearing period. As a digression for a moment we may recall the fact that the Scottish registers at one time contained this information, which has been ably utilised in connexion with the subject of maternal fertility in that country. In England, nevertheless, there are sufficient grounds for stating that during the past 30 years about 15 per cent. of the decline in the birth-rate (based on the proportion of births to the female population aged 15–45 years) is due to the decrease in the proportion of married women of conceptive ages, and that over 7 per cent. is due to the decrease of illegitimacy. With regard to the remaining 78 per cent. of the decrease Sir William Dunbar pointedly remarks that although some of the reduced fertility may be ascribed to changes in the age constitution of married women there can be little doubt that much of it is due to deliberate restriction of child-bearing.

MEDICINE AND THE LAW.

Medical Certificates for School Children.

Mr. Paul Taylor recently made the following observations at the Marylebone police-court with reference to the class of cases in which parents are summoned for the non-attendance of their children at school through illness as to which no medical certificate is forthcoming. The learned magistrate said: "I look upon it as very important that the poor should be able to obtain such certificates without payment, and it would be of great assistance to me if they could. I am often told that these poor people really cannot afford to pay for a certificate. A hospital doctor should not be expected to give a free certificate." Mr. Taylor had also said during a discussion as to the course which might be adopted that in his opinion there should be a public medical official paid out of public funds to give certificates for the purpose indicated and a witness from the education department of the London County Council had intimated that some such suggestion had already been laid by him before the Council. The obvious necessity that there should be medical certificates in cases of absence from school through alleged illness will, no doubt, lead to provision being made some day for the obtaining of them by those too poor to pay for them themselves, but the question how they should be obtained and paid for is not very easy to answer. The provision of fees payable from public funds to the medical man attending the patient should commend itself to the medical profession rather than the institution of a public official to inspect and to certify with regard to cases under the treatment of a private practitioner. Such a course would not, however, be without its drawbacks, and the question of expense is no doubt one which would be regarded as a serious one by the ratepayer, both generally and with regard to the comparative cost of any plans put forward.

Fergusson v. *the Malvern Urban District Council.*

After a trial lasting 11 days Dr. J. O. Fergusson has recovered a verdict for £7500 damages against the Malvern district council on the ground that an outbreak of enteric fever at the hydropathic establishment conducted by him, and in respect of which he has already had to pay heavy damages to various plaintiffs who contracted the disease in his establishment, was due to the contamination of his water-supply with sewage, for which contamination the council was responsible. Dr. Fergusson is to be congratulated on the result of the case and all the more so as the defence involved serious charges against him of want of care in the provision of water for the inmates of the house under his control. No fewer than seven questions were eventually left to the jury and it is to be observed that a point of law may be discussed hereafter in the Court of Appeal upon the answers given to two of these, by which the jury found that the plaintiff had no proprietary right in certain water to the contamination of which the enteric fever was ascribed and which flowed into his tank and that he had no licence to use it. By their other answers the jury found that the defendants were guilty of negligence in permitting sewage to escape from their sewer and that the plaintiff was not guilty of contributory negligence in permitting the contaminated water to be conducted to his tank as it was conducted; that the escape of the sewage was the sole cause of the outbreak of enteric fever; and that the outbreak would not have been prevented by reasonable care on the part of the plaintiff.

£500 Damages for Libelling a Medical Practitioner.

Two actions for libel brought by a medical practitioner against newspapers and arising out of the same facts were brought to a conclusion recently before Mr. Justice Darling in the King's Bench Division. In the first the defendants (Edward Lloyd, Limited, proprietors of the *Daily Chronicle*) apologised and settled the action by payment of £25, which they had already paid into court, together with £100 to cover the plaintiff's costs. In the second action the *Star* Newspaper Company, Limited, were the defendants, and evidence was called on behalf of the plaintiff before a settlement was arrived at by which the defendants agreed to pay to the plaintiff £500 damages, with costs as between solicitor and client. The facts with regard to which the two newspapers involved had published matter calculated to injure the plaintiff were of an unusual character and arose out of the crimes of the man Brinkley arrested in April, 1907, for the murder of Mr. and Mrs. Beck by poisoning and afterwards convicted and executed. It appears that when inquiry was instituted as to BRINKLEY'S antecedents it was found that towards the end of 1906 a woman named Bume, living at the house where he was subsequently arrested, had had a fit, and that the plaintiff, Mr. M. J. Williams, who had been called in to attend her, had found her already dead on his arrival. He had afterwards been asked by Brinkley to certify as to the cause of death but had naturally refused to do so and had given evidence at the inquest which followed after making a post-mortem examination by the coroner's order. The evidence which he gave was to the effect that the deceased died from apoplexy and the jury so found. As no question of foul play had arisen at the time of Mrs. Blume's death and as no special inquiry with a view to detect poison had taken place it was thought desirable when the deaths of Mr. and Mrs. Beck occurred to ascertain whether evidence of crime could be traced in the former case also, and by the order of the Home Secretary Mrs. Blume's body was exhumed

Finlayson would like to have had the examiners examined and see if they were really worth 100 per cent.

I shall now proceed to criticise my critic and see what percentage of *stress* and *strain* this *elastician* will stand before we come to the breaking point. I have no wish to *snap* him *abruptly* so I shall apply the *stress* gently.

He lays down a very rigid definition of *elasticity*, to which I offer no objection, though it is not one to which professional physicists closely adhere, as it enables me to see what he intends to mean. Of course, your readers, like myself, expect that having settled the matter according to his own ideas, he at least would stick to the definition which he has adopted—I say adopted because after all the definition is not his own. Let us see how his definition works out. He tells us that solid bodies like steel and ivory are much more *elastic* than even such perfectly *elastic* bodies as the various gases, but he forgets to say that the range of elasticity of those highly elastic bodies is very limited; if you exceed that extremely narrow limit you fracture or rupture or break the body, or you may give it a permanent *set*, so that it does not return to its original form. If you attach a certain weight to a steel wire sufficient to stretch it one-twentieth of an inch, then double the weight will stretch it one-tenth of an inch, but if you go on doubling you quickly exceed the limit of its elasticity, and the wire either *snaps* or takes a permanent *set* and will not return to its original length on the removal of the weight—you have exceeded the very narrow limit of elasticity in this highly elastic body. If you take the blade of a sword made of finely tempered steel you will find it much more elastic than the iron or steel from which it was made, yet, according to Dr. Samways, I presume this should not be, because he says "elasticity is a property fixed in amount for any substance." Again, if you take the sword and convert it into a large tube of the same length it again becomes rigid, and if you attempt to bend the tube the force required quickly breaks it. How is it that the great range of the sword's elasticity has practically disappeared? The molecules on the convex side of the attempted curve would now have a much longer way to move than previously, and when sufficient stress is put on to move them and manifest their elasticity those on the outer curve jump apart beyond the limits of their elasticity and the tube breaks. The same thing happens with such a highly elastic body as glass. This is all very nice but it does not fit in very well with medical ideas of elasticity as found in the human body. According to Dr. Samways' definition the ribs are much more elastic than the costal cartilages, the femur much more elastic than the ribs, and the more rigid the chest walls the more elastic do they become *as it takes a* greater force to produce any given deformation. An unyielding rope is more elastic than an extensile one; it is true that it snaps more readily, but what does Dr. Samways care for that when it requires more force to produce a given amount of stretch. "Rubber yields considerably to a small force and is therefore comparatively inelastic. It possesses the quality of elasticity to a striking degree but in a low measure." This last sentence is a distinct contradiction of terms; it is a misuse of the English language to say that anything that possesses a quality in a low measure has it in a striking or high degree. It is not a question of small quantity and high tension like the high frequency current, because it is just in the tension that the rubber is deficient.

Having some slight regard for your space I shall not diverge into a sidepath to discuss the unconscious cerebration of Dr. Samways' cat as she lay curled up and quietly asleep on the hearth dreaming of her far-off home, situated perhaps south-south-east by south from the hearth, and wondering when the potential energy of her limbs would become kinetic and enable her to speed her way through thick woods and devious paths unaided by a compass; nor shall I soliloquise on the dormant moral *qualities of his* untried gentleman or saint who, unlike an elastic body, does not require a double force to resist a double temptation. There may be some irreverent enough to suggest that *this gentleman is an imbecile or* a general paralytic. I know several men who would have no hesitation in writing a cheque for a sum much more than sufficient to pay off the National Debt; by such the temptation of a five-pound note is easily resisted. These may be, and no doubt are, very interesting psychological studies, but they have no more to do with elasticity than the moon has to do with green cheese.

When Dr. Samways says that I am "certainly in error" he simply means that I do not agree with his definition of elasticity, and under the circumstances I am very pleased to be in error. "This property of a substance," to which according to Dr. Samways *you* can neither add to nor take therefrom, "is measured quantitatively by the amount of force required to produce a given distortion in a given volume or unit of the substance." This is uncommonly like my statement, but perhaps not quite so well expressed, that the more taut or stretched the lung (of course, within the limits of its elasticity) the greater will be its elasticity or tendency to recover its form after being stretched. If a force of two pounds stretch a piece of rubber one inch, four pounds will stretch it two inches, and it will resist further stretching by a force of four pounds, and when the weights are removed it will recover its former dimensions by a force gradually tapering down from four pounds to nothing.

Now listen to what this critic says: "Its elasticity and tendency to recover cannot be measured by stretching; it was inherent in it and fixed in quantity from the first." Here he uses "elasticity" as an abstract quantity of the substance and he uses "*tendency to recover*" as absolutely synonymous, although I have just shown that it is a measureable force equal to the power to which it has been submitted. He might as well use potential and kinetic energy as synonymous terms, or mass and weight as one and the same thing. From experiments on tuning-forks it has been found that no matter how slightly or how closely the limbs are approached or how far they are separated it takes them the same time to recover their original position, and therefore it follows that the greater the force used the greater must be the tendency to recover. The vibrations of the tuning-fork from the greatest excursion down to silence all occupy the same time, so that with the diminution in the excursion the velocity is also *diminished*.

Here is another example of his way of reasoning: "In this way the negative pressure in the pleural sacs is created by muscular effort and not by elastic recoil of the lungs." He forgets that if the lungs were non-elastic and non-resistant but free to follow the movements of the chest-walls there would be no negative pressure in the pleural cavities. This is what practically happens in emphysema where the lungs have lost their elasticity and gradually expand until at last even the recoil of the chest walls is lost. "It would be even greater, as Dr. Campbell contends, if the lungs did not expand." In this case the inspiratory muscles would have to pull out unaided the thoracic walls against the atmospheric pressure, and this I believe they cannot do. "If the lungs be comparatively rigid the whole force of the inspiratory muscles can be expended on reducing the intrapleural pressure." For how long? The fractional part of a second; under such circumstances the lungs could only be taut at the end of inspiration, and relaxed during the rest of the respiratory phase. "One would have imagined that the elastic tissue would have arranged to be at rest when the thorax was at rest, but it strangely chooses, from birth onwards, never to assume the unstretched *condition*." Well, nature does not seem to have taught him much when he cannot see such obvious utility, and all I feel inclined to say is, thank God there was no amateur physicist present at the *Creation*.

If you allow this discussion to go on for about a couple of years I think we might settle the meaning of *elasticity*, if some new definition does not crop up in the meantime. Then I shall leave the rest of the English language to Dr. Campbell and Dr. Samways to settle, but I would take the liberty of suggesting to them that they might start with the distinctions between tweedledum and tweedledee which would serve as much practical utility as their contributions to elasticity.

I am, Sir, yours faithfully,

JAMES BARR.

Liverpool, Feb. 8th, 1908.

MINISTRY OF PUBLIC HEALTH.

To the Editor of THE LANCET.

SIR,—The article in the current number of THE LANCET on a Ministry of Public Health emphasises the crux of the position. It is quite a necessity that such a Minister should, in general terms, have greater powers for public health than at present exist, and equally so his influence be real with the Treasury. This is clearly recognised by myself and others in this country who take an active interest in the matter, such as Sir T. Clifford Allbutt. It is shown in articles dealing with the subject since 1902, in which it is which had been 154 and 190 in the two preceding weeks, further rose last week to 192; they caused annual death-rates equal to 2·1 in Sheffield, 2·2 in Birkenhead, 2·4 in Gateshead, 2·5 in Aston Manor and 2·9 in Warrington. The 73 deaths referred to diphtheria showed also a further increase upon the numbers in the two previous weeks, and included 21 in London, three in East Ham, four in Birmingham, two in Stockport, three each in Liverpool and in Manchester, nine in Salford, and three in Leeds. The deaths from measles, which had declined from 141 to 83 in the four preceding weeks, further fell last week to 71; this disease, however, caused death-rates equal to 1·3 in Preston, 1·4 in South Shields, and 1·5 in Burnley. The fatal cases both of diarrhœa and of scarlet fever showed a slight increase; the annual rate from the latter disease was equal to 1·5 in Smethwick and 1·6 in Walsall. The deaths from "fever" were again below the average, but included six in Liverpool and three in Salford. The number of scarlet fever patients under treatment in the Metropolitan Asylums and London Fever Hospitals, which had steadily declined in the nine preceding weeks from 5581 to 3916, had further fallen to 3367 on Feb. 8th; during the week ending on that day 433 new cases were, however, admitted to these hospitals, against 380 and 405 in the two previous weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 499, 455, and 432 in the three preceding weeks, further declined during the week under notice to 395, but exceeded by 27 the corrected average number in the corresponding week of the five years 1903–07. The causes of 51, or 0·9 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Nottingham, and in 46 smaller towns. Seven uncertified causes of death were, however, registered last week in Liverpool and five each in Birmingham, Sheffield, and Manchester.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 22·2 and 22·3 per 1000 in the two preceding weeks, further rose to 23·5 in the week ending Feb. 8th, and exceeded by no less than 5·2 the mean rate during the same week in the 76 English towns. Among the eight Scotch towns the death-rates ranged from 16·3 and 21·4 in Perth and Aberdeen to 25·4 in Dundee and 31·4 in Leith. The 827 deaths in these eight towns exceeded by 42 the number returned in the previous week, and included 132 which were referred to the principal epidemic diseases, against 158, 142, and 123 in the three preceding weeks; of these, 64 resulted from measles, 32 from whooping-cough, 14 from diarrhœa, 12 from "fever," five from diphtheria, three from scarlet fever, and two from small-pox. These 132 deaths were equal to an annual rate of 3·7 per 1000, which exceeded by no less than 2·3 the mean rate last week from the same diseases in the 76 English towns. The 64 fatal cases of measles corresponded with the number in the previous week, and included 55 in Glasgow, three in Greenock, and two in Dundee. The 32 deaths from whooping-cough exceeded the number in the previous week by six; nine occurred in Glasgow, eight in Edinburgh, six in Leith, and three in Dundee. Of the 14 deaths attributed to diarrhœa, seven were returned in Glasgow, three in Dundee, and two in Aberdeen. Of the 12 deaths referred to "fever," seven were certified as cerebro-spinal meningitis and five as enteric fever; these 12 deaths included seven in Glasgow and four in Dundee. Three of the five fatal cases of diphtheria and two of the three of scarlet fever were returned in Glasgow. Both of the fatal cases of small-pox occurred in Leith. The deaths referred to diseases of the respiratory organs in these eight towns, which had been 178 and 179 in the two preceding weeks, declined to 171 in the week under notice, and were seven below the number from the same diseases in the corresponding week of last year. The causes of 22, or 2·7 per cent., of the deaths in these towns last week were not certified or not stated; in the 76 English towns the proportion of these uncertified deaths last week did not exceed 0·9 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 31·2, 29·5, and 25·5 per 1000 in the three preceding weeks, further declined to 22·3 in the week ending Feb. 8th. During the first six weeks of the current quarter the death-rate in the city averaged, however, 26·7 per 1000, whereas the mean rate during the same period did not exceed 16·0 in London and 19·5 in Edinburgh. The 169 deaths of Dublin residents registered last week showed a further decline of 24 from the high numbers in recent weeks, and included but four which were referred to the principal epidemic diseases, against nine and six in the two preceding weeks; these four deaths included two from "fever" and one each from measles and whooping-cough, no death being registered either from scarlet fever, diphtheria, small-pox, or diarrhœa. These four deaths from epidemic diseases were equal to an annual rate of 0·5 per 1000, the death-rate from the same diseases last week being 1·3 in London and 1·5 in Edinburgh. The 169 deaths from all causes in the city last week included 19 of infants under one year of age and 70 of persons aged upwards of 60 years; the deaths of infants showed a marked decline, but those of elderly persons were again exceptionally numerous. Six inquest cases and four deaths from violence were registered during the week, and 64, or 38·0 per cent., of the deaths occurred in public institutions. The causes of five, or 3·0 per cent., of the deaths in the city last week were not certified; in London the causes of all but three of the 1629 deaths were duly certified, while in Edinburgh the proportion of uncertified deaths was 2·7 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeon R. Miller to the *President* for Deptford Yard.

ARMY MEDICAL SERVICE.

Colonel John F. Williamson, C.B., C.M.G., is placed on retired pay (dated Feb. 6th, 1908).

ROYAL ARMY MEDICAL CORPS.

The undermentioned Captains to be Majors (dated Jan. 29th, 1908):—Anthony H. Waring, William A. Ward, Edward W. W. Cochrane, Arthur H. Morris, Samuel A. Archer, and Robert W. Clements.

Captain John I. W. Morris retires, receiving a gratuity (dated Feb. 8th, 1908).

Lieutenant Charles P. Thomson is seconded for service with the Egyptian Government (dated Jan. 1st, 1908).

Major F. G. Faichnie has taken up duty in the London District and Lieutenant E. De la Cour has left for India. Lieutenant-Colonel W. G. Birrell has embarked for Mauritius.

The undermentioned Lieutenants are confirmed in that rank:—Winfrid K. Beaman, George F. Dawson, Thomas McC. Phillips, Harry V. B. Byatt, Harold S. Dickson, Gerald Petit, Forbes J. Stuart, John B. Hanafin, Harold Gibson, William P. O'Farrell, John A. Renshaw, Ralph de V. King, Cecil T. Conyngham, Dalziel B. McGrigor, Richard G. S. Gregg, William A. Spong, Herbert W. Carson, Henry P. Hart, Francis T. Dowling, Richard F. O'T. Dickinson, Harold T. Treves, Arthur E. B. Jones, Benjamin A. Odlum, and Alexander Hendry.

ROYAL ARMY MEDICAL COLLEGE.

Colonel Douglas Wardrop to be Commandant and Director of Studies, vice Lieutenant-Colonel H. E. R. James, R.A.M.C. (dated Feb. 4th, 1908).

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Charles G. Maclagan to be Surgeon-Major (dated Jan. 29th, 1908).

VOLUNTEER CORPS.

Rifle: 7th Volunteer Battalion, The Royal Scots (Lothian Regiment): Supernumerary Surgeon-Lieutenant-Colonel J. B. Ronaldson (Brigade Surgeon-Lieutenant-Colonel, Senior Medical Officer, 2nd Lothian Volunteer Infantry Brigade) is granted the honorary rank of Surgeon-Colonel (dated Jan. 20th, 1908). 5th (Glasgow Highland) Volunteer Battalion, The Highland Light Infantry; Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel Q. Chalmers resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated Jan. 21st, 1908).

doubtful, however, whether the most skilful œsophagoscopist would have had success in the case quoted owing to the infant's size and age, but it is comforting to know that if he fails intestinal peristalsis with the patient in the recumbent posture may successfully remove the offending body without having recourse to a cutting operation.

I am, Sir, yours faithfully,

Oldham, Feb. 2nd, 1908. J. S. MANSON.

IS THE DEATH-RATE THE BEST MEASURE OF SEVERITY IN DISEASE?

To the Editor of THE LANCET.

SIR,—May I ask you to insert the following correction in my article published in your last number under the above title? In Table II. the grand total should be 1823·8, not 183·8. I am, Sir, yours faithfully,

New Cross-road, S.E., Feb. 11th, 1908. F. M. TURNER.

THE MEDICAL INSPECTION OF SCHOOL CHILDREN.

To the Editor of THE LANCET.

SIR,—The Memorandum of the Education Board on the Medical Inspection of School Children recommends that it shall be carried out "under the direct supervision of the medical officer of health," and goes on to say that "some authorities will find that the teachers are able to undertake without undue strain a share of the work of furnishing data respecting each child and even perhaps to carry out some portion of the inspection." As a matter of fact, the teachers, with the aid of a school nurse, could carry out the whole inspection after a fashion; the teacher could fill in the names, ages, addresses, heights, and weights of the children, and could test their sight and hearing; the nurse could inspect their skins, teeth, and throats. Finally, to the children found defective the head master or mistress could give cards advising their parents to take the child to an oculist, dentist, aurist, or, if it is thought he could be trusted, to an ordinary doctor.

But the Memorandum does not stop at inspection, but goes on to say that school nurses are "to assist in carrying out medical advice concerning simple complaints"; similarly the medical officer (education) of the London County Council tells us in his report that "it is quite absurd to say a nurse cannot recognise ringworm." It is; a nurse can do anything she is trained to; woman doctors recognise and treat all diseases, and what makes the woman doctor is not the degree but the training before and after graduation. Nurses could therefore treat cases under the supervision of the medical officer of health. That they should do so is, I submit, absolutely wrong; it is as if in a hospital the surgeons and house surgeons were abolished and the surgical cases treated by the nurses under the supervision of the sanitary engineer. Local authorities themselves do not seem quite to approve of nurse treatment and are beginning to appoint junior members of the profession to hold office for a year or two as assistants to the medical officer of health, primarily to inspect school children, but also to discharge any other duty their chief may delegate to them. But this, too, is wrong; the treatment of disease is not a minor matter, one to be safely left to medical underlings and "suitable persons"; the treatment doctor must remain the equal of the more recently invented preventive doctor. To separate simple ailments from complex is impossible; the man who never sees a simple case will not understand a complex one; the profession cannot survive the confiscation of its experience.

Whether or not there should be State treatment is a matter on which opinions will differ; it will be decided not by us but by education authorities; we, however, can share in the decision by our votes and by becoming members of local councils and of health and education committees. If State treatment is to come it must be properly carried out; there will probably be no question between whole- and part-time appointments, for there will be no work left for doctors to do in their own time; private practitioners may read their fate in that of private teachers; voluntary hospitals in that of voluntary schools.

I am much obliged to "A Lawyer" for his answers to my former questions.[1] If his kindness is not exhausted I should like to ask one more. If a medical officer of health supervises the treatment of simple ailments by a school nurse is he liable to actions for malpraxis; and can the General Medical Council remove his name from the Register for covering? If this is done can he continue to hold his office? I am, Sir, yours faithfully,

Feb. 8th, 1908. J. S.

THE DESTINY OF CASE-BOOKS.

To the Editor of THE LANCET.

SIR,—I had an experience quite as unpleasant as that related by your correspondent "M.R.C.S." concerning the destiny of case-books. Some years ago I consulted a West-End specialist. I knew him pretty well and he showed me his case-book then in use, and for my comfort explained that it was written in a shorthand invented by himself. A few months later this physician died and I received an envelope which contained a letter from his widow stating that she had disposed of the practice to Dr. X. There was another letter from Dr. X explaining that he had purchased the practice and had all the case-books of the deceased consultant. Remembering that the case-books were in cypher I hoped they would be useless; their proper destination was certainly the fire. The first doctor was a gynæcologist.

I am, Sir, yours faithfully,

Feb. 8th, 1908. DOMINA.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool Royal Infirmary: Annual Meeting; The Position of the Abattoirs.

THE annual meeting of the subscribers to the Royal Infirmary was held on Jan. 29th. Allusion was made by the treasurer in flattering terms to the retirement of Mr. Rushton Parker from the active staff. Mr. Parker had had a connexion of 30 years with the Royal Infirmary. For 12 years as assistant surgeon and 18 years as honorary surgeon he concentrated his care and attention on the hospital to which he unsparingly devoted his best ability and time. Beds had been endowed during the year by Miss A. W. Hignett, Mr. James Lister, and Mr. Bruce Ismay in memory of their parents. The contribution from the Hospital Sunday and Saturday Funds had been £3378. Legacies, always a varying source of income, amounted to £1246. The total expenditure was £16,208 and the ordinary income was £14,034. On balance, £2600 having been transferred from the long-lived but now nearly exhausted maintenance fund, the charity was still in debt to the amount of £2335, and the convalescent fund was in debt to the extent of £164. 3875 patients had been treated in the wards, 20,434 as out-patients, and for redressing of wounds, &c., 52,082 had attended. The Lord Mayor (Dr. Richard Caton), in proposing the adoption of the report and accounts, said that he trusted that such charities as the Royal Infirmary would not, as some people thought, be placed upon the rates. The present method of hospital governance was infinitely better than anything that could take its place in the form of State-aided hospitals. He trusted that they would do everything in their power to carry on that and other hospitals on their present basis. He regretted to find that the committee was in debt as regarded the convalescent fund, as that was such an important matter which led to the relief of their bed accommodation. Mr. T. H. Bickerton alluded to the question of the possibility of the renewal of the lease of the abattoirs in their present position near the infirmary. He expressed the hope that the corporation would not on any account consent to the renewal of the lease. The Liverpool Medical Institution had prepared a resolution to which some 200 to 250 medical men had attached their signatures, which would be sent to the Lord Mayor for presentation to the city council. He hoped that the city would confirm the opinion of the medical profession that abattoirs should not be allowed to remain in densely populated centres. Mr. G. G. Hamilton said that his operating theatre in the infirmary was only at a short distance from the abattoirs, and he joined in the hope that the lease would not be renewed. Several times he had had to stop surgical operations to get rid of flies which were now recognised as such a medium for spreading disease. If it were proved that the flies had a materially affect their pressure against the internal surface of the thoracic parietes, but if the lungs were not elastic and free to move with the thoracic parietes even this great pressure could not keep the lungs taut and there could be no intrapleural negative pressure. We are therefore forcibly driven to the conclusion that at least healthy lungs can only be kept *taut* by their elasticity. If the lungs were non-elastic and braced up from root to parietes, then each time the intrapulmonary pressure exceeded the extrathoracic atmospheric pressure the lungs would cease to be *taut*, and this would occur with every expiration. In this case the lungs would be *taut* at the end of inspiration and during this fractional part of a second would render respiratory assistance to the circulation, but during the rest of the respiratory phase there would be a positive obstruction to the circulation. With an *intermittent* tension or stress the *tautness* of the lungs can only be *continuously* maintained if they be elastic.

---

[1] THE LANCET, Jan. 4th, 1908, p. 51.

Third.—He falls foul of his quondam friend, Dr. D. W. Samways, for failing to recognise his nice distinction between the tautness of the lungs and the elasticity which keeps them taut. "Let us for argument's sake suppose the lungs in the case in question suddenly to be rendered perfectly non-elastic, their tautness, however, remaining unaltered." He really upsets my gravity, and I would suggest to him that a much neater way of putting it would be, suppose we suppose an impossibility. If a stretched piece of rubber suddenly lost its elasticity, would it remain taut? I trow not. I have often seen rubber lose its elasticity but I have never afterwards seen it remain taut. With a constant weight attached to a piece of fibroid tissue it might remain tense, but with an intermittent stress such as occurs in respiration it could not continue *taut*.

Fourth.—He refers to the experiments of Valsalva and Müller which, I think, were much more fully explained in my paper on the Effects of Respiration on the Circulation in the *British Medical Journal*, April 20th, 1907. In his statement of the Valsalva experiment there is nothing new but in Müller's experiment he says what is not true: "If at the end of a deep expiration, when the pulmonary tissue is relaxed and the lungs cease to exercise traction, a powerful inspiratory effort be made with closed glottis, the greatly lowered intrapulmonary pressure thus effected will give rise to considerable traction." At the end of deep expiration the pulmonary tissue is not relaxed and the lungs do not cease to exercise traction. In this experiment a big chest, like Dr. Campbell's, might produce a fall in the intrapulmonary pressure of 80 millimetres of mercury, which would reduce the intrapulmonary pressure from 760 to 680 millimetres of mercury. The elasticity of the lungs being a constant can be neglected, and, moreover, we are not at present considering the intrapleural or intrathoracic pressure. It is ridiculous to say that 680 millimetres of mercury can make the lungs more taut than 760 could. This great fall in the intrapulmonary, and consequently in the intrathoracic, pressure makes an enormous difference to the blood-vascular cavity within and without the thorax, so the blood is driven in, not sucked in, with a force of 80 millimetres of mercury *plus* the elasticity of the lungs. It is really painful to me to have to point out such palpable errors.

Fifth.—"Hypertrophous emphysema" is a misnomer. Hypertrophy means increased nutrition and increased function, there is neither in emphysema. "The inspiratory muscles are throughout life ever on the watch to maintain pulmonary tautness at a certain mean level, with the object of maintaining a constant suction on the heart, and thus facilitating diastole," &c. So far as the inspiratory muscles, which only act intermittently, are concerned they can only maintain tautness at the end of inspiration and apart from the elasticity of the lungs can maintain no constant suction. David Barry at the beginning of last century did not, and could not, fall into such egregious error. It would be a great waste of time and space to follow his suppositions about what happens, or should happen, in cases of "hypertrophous emphysema." It is sufficient to say that as the elasticity of the lungs disappears so the intrapleural and intrathoracic negative pressures gradually lessen.

Sixth.—Now for his fibroid phthisis. "If the lungs are not taut, and if pulmonary traction is not increased, how are we to account for the sinking in of the upper part of the chest not infrequently met with in chronic phthisis, as well as in the more acute form of the disease?" Has he never seen the chest walls caved in by the atmospheric pressure in a child suffering from laryngeal diphtheria? This condition simply proves that the inspiratory muscles are quite incapable of expanding the chest beyond the expansile power of the lungs. The infraclavicular spaces may get flattened whether there be many adhesions or not. The fibroid apices do not drag in the chest walls, but being non-elastic they take no part in filling up the thorax during inspiration; the remaining elastic portions increase the *negative pressure in the whole thorax* during inspiration, and consequently the portions of the chest over the non-expansile portions of the lungs are flattened in, not dragged in; in the acute forms of the disease there are no adhesions to drag them in.

Seventh.—This paragraph is entirely made up of suppositions without an attempt to prove any of them.

Eighth.—There is here and elsewhere a little assumption at not understanding what I mean. I can assure him once for all that when I say intrapleural I mean intrapleural, intrathoracic I mean intrathoracic, and intrapulmonary I mean intrapulmonary, and I am not going to assume that there is any one of your readers who does not know as well as Dr. Campbell the difference in these expressions. The rest of the paragraph is chiefly made up of irrelevant remarks about Müller's and Valsalva's experiments. The conditions of these experiments are well known. I have previously shown that in Valsalva's experiment the intrapulmonary pressure can be raised so high as not only to abolish the intrapleural negative pressure but raise the intrathoracic pressure to such a *positive height as to shut out the blood from the chest*, reduce the heart to about half its size, and almost bring it to a standstill. In this experiment the lungs are made *very taut* under a pressure of about 860 millimetres of mercury. What, then, is the use of talking about the *suction* of the chest depending on the *tautness* of the lungs?

Ninth.—He is driven to very narrow straits when he says: "I neglect to mention bronchiectasis and the enlargement of tubercular cavities as a means of filling up enlarged chests in cases of fibroid lungs." Emphysema still remains the principal cause.

Tenth.—Here he entirely begs the question when he says: "In so far as the bulbous condition of the fingers in fibroid phthisis is due to obstructed circulation it results from the widespread destruction of the pulmonary blood-vessels." It does not matter how many blood-vessels were destroyed, if *his taut lungs constantly maintained a negative intrathoracic pressure there could be no obstruction to the systemic venous circulation and there should be no bulbous fingers.*

Eleventh.—He tries to wriggle out of this close corner by saying that I refer to "non-elastic lungs" and he to "*comparatively* non-elastic lungs." This is a degree of comparison which in no way affects his bubble which I pricked.

Twelfth.—He does me the credit of quoting a very long abstract from my letter which is sufficiently explicit and which he vainly tries to subvert. Now the inspiratory muscles are "just competent to expand the chest to its potential maximum, as may be observed in advanced cases of hypertrophous emphysema." In these cases the lungs lose their elasticity, consequently they cease to be taut, and the *intrapleural negative pressure diminishes or disappears.*

Thirteenth.—In conclusion he hopes that "the energy expended may not be entirely lost on Sir James Barr." Well, it all depends on how you look at it; personally, I think he has wasted a lot of my valuable time over a trivial storm in a teapot. The only consolation I have is that I may have stimulated some of your readers to study the question of elasticity as applied to the lungs, and may have prevented them falling into the traps of error set for them by Dr. Harry Campbell. Consolation prizes are not, as a rule, very valuable, so if he wish my forgiveness he should send me a cheque for not less than 100 guineas.

I must now deal with the letter of Dr. Samways in your issue of Jan. 25th.

Dr. Samways intrudes as an uninvited guest to this feast of reason and flow of soul in order to set both Dr. Harry Campbell and myself right. I am always willing, nay, anxious, to learn, but in order that my knowledge may be based on a firm foundation I must inquire into the quality of the instruction and the capacity of the instructor. As my old friend, the late James Finlayson, said about examiners, that the first part of their work was to mark themselves up 100 per cent., and then accordingly, as they thought that the examinee approached their ideal standard of perfection they gave him anywhere between 80 and 100 per cent., but Dr.

and Dr. W. T. Ritchie, Mr. Henry Wade, and Dr. W. E. Carnegie Dickson were reappointed to the pathological department for one year. These latter appointments are carried on from year to year.

Edinburgh Royal Medical Society.

The annual dinner of this society was held on Feb. 5th, the chair being occupied by the senior president, Dr. A. C. B. McMurtrie. Mr. Jonathan Hutchinson was the guest of the evening. The toast of the guest was proposed by the chairman and in his reply the former advised the members to keep the dreams of youth before them and to increase their zeal in medical pursuits as life advanced. In proposing the toast of the society Mr. Hutchinson spoke of the unsatisfactory character of examinations and threw out some novel ideas as to how they might be improved. A number of invited guests had been unable to accept the invitation to be present owing to other engagements. In fact, this dinner clashed, unfortunately, with at least three other medical meetings.

Edinburgh Indian Students Association.

The annual dinner of this association was held on Feb. 6th. Lord Salvesen was the chief guest and in his hands was placed the toast of "India and the Edinburgh Indian Association." Several of the University professors were also present. The proceedings passed off most creditably to the student organisers.

Honour to Dr. J. O. Affleck.

Many of the old students of clinical medicine in the Edinburgh Royal Infirmary will be pleased to know that the University of Edinburgh is to confer on Dr. J. O. Affleck the honorary degree of LL.D.

The Vacant Regius Chairs in Edinburgh and Glasgow.

The filling of both the chair of clinical surgery in Edinburgh and of that of practice of medicine in Glasgow is in the hands of the Secretary for Scotland. With regard to the first of these there are several local applicants; indeed, all the members of the senior surgical staff in the infirmary and two or three outside surgeons are spoken of. With regard to the Glasgow chair it is understood that in addition to applicants from Glasgow there will probably be at least two or three from Edinburgh. There are, of course, many surmises but there is no trustworthy information.

The Royal Hospital for Sick Children, Glasgow.

The twenty-fifth annual report of this hospital has just been issued and forms very interesting reading. Three years after the hospital was opened the number of cases treated per annum was 300, now it is 11,000. Three years after the dispensary was opened the attendance there was 5000 per annum, now it is 11,000 per annum. The average daily number under treatment in the wards of the hospital during the past year was 67·1 and the average duration of residence was 23·83 days. The country branch at Drumchapel has proved a most valuable extension of the hospital. The wards there have always been full and many more than the regulation number of 26 cots could easily have been utilised. In connexion with the work at the dispensary, also, it is noted that the resident sisters and nurses visited at their own homes 431 cases which could not be taken to the dispensary. The ordinary income for the year was £6819, as compared with £6469 in the previous year. The ordinary expenditure was: hospital, £4995; country branch, £1497; and dispensary, £1369. This leaves a deficit of £1042. The report refers to the movement that has been inaugurated for the raising of money for the rebuilding of the hospital on a more suitable site, as, apart from the lack of accommodation in the hospital itself, the present site is now crowded with buildings, surrounded by high tenements, and is next door to a veterinary college where diseased animals are treated. The directors last year drew up a statement of the needs of the hospital and issued an appeal for £100,000 to enable them in the first place to build a hospital to contain from 200 to 250 cots on a site in Glasgow where the children will get the maximum of fresh air and sunshine, and secondly, to extend materially the hospital accommodation in the country. As a result of this appeal at the close of the year the subscriptions totalled £60,000, of which sum £4500 were raised by a "shilling fund" started by the proprietors of the *Glasgow Evening News*. At the present time the directors are negotiating for a suitable site.

Interesting "Milk" Prosecutions.

In view of the present outbreak of enteric fever in Glasgow and Partick two interesting prosecutions took place in Partick police-court recently. The accused were both dairymen in the burgh and the charge against them was that of allowing the message boys on their respective milk carts to sit upon vessels used for the purpose of carrying milk. This constitutes a contravention of a section of the burgh regulations, which is to the effect that no person should rest his body on vessels used for holding milk. The defence in both cases was that the vessels were empty at the time and would have been scalded before being used again. In both cases it was held that the by-law had been contravened, but the defendants were dismissed with an admonition.

Dumfries and Galloway Infirmary.

The report for the past year states that 788 in-patients were dealt with, which constituted a record for the hospital. The ordinary income amounted to £3419 and the ordinary expenditure to £4216, showing a deficiency of £967, but, on the other hand, legacies were received during the year to the extent of £3000. At the annual meeting a protracted discussion took place with regard to a complaint that a patient had been sent into the hospital and carried from the ambulance to the operating theatre where he was operated on without any diagnosis and that he died in consequence. It was decided that there was no ground for complaint.

The Epidemic of Enteric Fever at Peterhead: Professor M. Hay's Report.

On Feb. 3rd, at a meeting of the Peterhead town council, Professor Hay's report on the epidemic of enteric fever was considered. The report is of considerable length and deals largely with the rise and spread of the epidemic. He notes at the outset that the situation of Peterhead, built on a headland with a considerable slope seaward, is favourable to a good system of drainage; but some of the drains are of the old-fashioned rubble-built type, and some of them are carried along streets parallel to the shore, thus losing the necessary slope that would render them self-cleansing. Also, while the newer buildings are provided with modern and efficient sanitary arrangements, many of the older houses have antiquated and even dangerous drainage arrangements and prove the need of the more strenuous enforcement of the Public Health Act. As regards the outlet of the town's sewage, the principal sewer south of the harbour does not seem to be carried sufficiently far out to sea, as there is a strong and nauseating odour in its vicinity. With regard to the water-supply Professor Hay remarks that, both from the inspection of the wells or springs and from chemical and bacteriological examination, the water was largely of the order of ordinary field-drain or subsoil water; also that at the beginning of the epidemic the water was open at many points to pollution. Much of the water was surface water from cultivated fields liable to manuring and there was no provision for filtering it. This danger was increased by the use of the town's refuse as manure. On Professor Hay's recommendation the sale of all refuse for manure was stopped to farms within the water-gathering areas and to dairy farms. With regard to the origin of the epidemic Professor Hay is of opinion that it was started by milk infection which planted a large number of cases throughout the town and that it was kept going mainly, if not wholly, through contact infection. The cases occurring in spots or patches favour this view, in contra-distinction to cases occurring in diffused areas, as would have been the case had the epidemic been started by water infection. He then proceeds to show that the further progress of the epidemic and the distribution of the cases were against the supposition that the water became infected, at least to any degree. He does not, however, defend the state of the water-supply which he thinks bad and in pressing need of reform. He afterwards goes on to specify what ought to be done to prevent a recrudescence, such as promptly notifying suspicious cases, having recourse to the Widal and other blood tests in obscure cases, examining any old cases with any suspicion of infectivity, getting rid of all obsolete and insanitary arrangements such as ashpits, and the stoppage of supplying domestic or ashpit refuse to dairy farms or farms within the gathering grounds of the water-supply for a year or two until enteric fever shall be stamped out.

Feb. 11th.

reasoned that such a Minister should have Cabinet rank and, if possible, have had an expert training.[1]

Surgeon-General Fulton writes that this question, which I propose to bring before the Congress on Tuberculosis at Washington, is engaging the attention of the American Public Health Association, which has appointed a standing committee, representing the United States, Canada, and Mexico, to promote such departments. Its next meeting will be at Winnipeg in the summer. That the various bodies in this country interested in public health will follow this lead I feel certain, and there is no time like the present for their action. I am, Sir, yours faithfully,

Brighton, Feb. 8th, 1903. F. G. BUSHNELL.

THE QUESTION OF HOODS.

To the Editor of THE LANCET.

SIR,—I noticed in the report of the quarterly meeting of the Council of the Royal College of Surgeons of England that the Council refused to accede to the fifth request of the meeting of Fellows and Members—viz., "That a hood should be added to the gown already worn by Fellows and Members." I consider the excuses very lame.

Firstly, "as the hood was generally understood to be distinctive of a degree, and in this sense it formed part of the academic costume of a university, it was considered that it would not be appropriate for a *college*." The *College* of Preceptors grants hoods to its Fellows and Licentiates; King's *College*, London, grants a hood to its Associates (A.K.C.); the *College* of Organists grants a hood to its Fellows; and all theological *colleges* grant hoods to their Licentiates who are not graduates of a university (*vide* "Whitaker's Almanack").

Secondly, "as hoods did not appear to be in general use among colleges of similar standing to the Royal College of Surgeons of England." The Council forgets that it was the *first* to grant a cap and gown to its Fellows and Members and was followed by the Royal Colleges of Surgeons of Ireland and Edinburgh and the Society of Apothecaries. So as the Council of the Royal College of Surgeons of England was the *leader* in the gown, so it should be in the hood.

I would suggest that the hoods be: for Fellows, the same shape as a Cambridge M.A. but made of crimson satin lined black; for Members, the same shape but made of black stuff lined with crimson satin.

I am, Sir, yours faithfully,

Feb. 7th, 1903. J. M. CARVELL.

To the Editor of THE LANCET.

SIR,—The present Council of the Royal College of Surgeons has thought fit to reject the resolution of the annual general meeting of Fellows and Members to grant a hood to its alumni. No credit can attach to it for the temporary delay of this obvious and advantageous adjustment, and especially as it only bases the objection to it on the want of precedence. Graduates of the Royal *College of Surgeons* have quite as much right to claim, and have often shown, their equality of attainments to those of many of the arts and professional degree holders, and with them equally to lay claim to possess the distinction of a hood.

Although the medical colleges in London have not yet taken up teaching, they, as of old tradition, belong to a university standard, and which has been almost always an antecedent in the history of the past formation of all universities. They belonged to a heightened status, and, provisionally, on a level with a university. From that position the Newcastle College of Medicine, the old College of Physicians before the decadence, the Liverpool University College, Owens College, Firth College, and other Midland colleges have all been on a sufficient equality and superiority to bestow the right, or *ad eundem* right, to grant hoods to their diploma or degree holders. So, although we do not so foolishly set such store as *the lawyers* do on perpetual precedence, still there undoubtedly is precedence for this reasonable accomplishment of possessing a hood by the Royal College of Surgeons, and in spite of whatever the Council chooses to say against me.

When supporting my resolution for a hood at the annual meeting, I spoke on what I thought was the origin of the hood. I think masters or teachers were the first ones to wear them, as early as the middle ages, in colleges as well as in universities. Surely, then, the old surgeons were exactly in that same position. For they, even more than the physicians or the university men, were called upon as masters and teachers to fully instruct professionally their students and their apprentices. But these masters of their craft on being formed into a college aimed at, and took, by their constitution, a much higher position still. Likewise when the physicians formed themselves into the self-same higher collegiate position, they all wore hoods. Indeed, Charles II.'s mandate of 1674, and onwards, forced upon the members the university grade, and which thus constituted the collegiate position. So the pronouncement of the present Council of the Royal College of Surgeons cannot rest justly on its negative argument.

The surgeons, as separate from the ancient illegitimate practitioners, had always been at the head of the profession, above the grocers, above the apothecaries, above the barbour-surgeons, and above any of the universities in their own art and craft, though for convenience they have joined one or other of those bodies. Thus, from a business point of view, it is ill grace enough for the Council to indulge what seems a perpetual neglect discriminately against the body of the College; whilst benefits and privileges keep on accruing more and more to outside opponent bodies, and very much to the detriment of its members. That is why I have traversed its statements, and wish it to acquiesce in the general needs of the situation. For it must be apparent if it accepted fresh control, by both Fellows and Members together, there would be an end to any of the antiquated subservience amongst such an educated body of members where they remain unable to ratify their own resolutions. Reference has been made above to the collegiate status of the physicians which justified the equivalent usage with the university of the hood. The only other medical body in London to search for any corresponding trace of conformity would be the Society of Apothecaries. And, by Mr. C. R. B. Barrett, it is recorded, in 1696, that the Livery of the Apothecaries, when the King (William III.) made a public procession, were in their allotted place, and they wore both gowns and hoods.

Again, quite outside the amply sufficient medical references, there do happen to be confirmatory precedents for granting a hood. Of course, the Royal College and Academy of Music are merely scholastic or training institutions and having certificates, and on that account they purposely remained unmentioned in my speech. But, besides music guilds containing graduates, both the College of Preceptors and the Royal College of Organists *have* attempted, in London, to satisfy the university standards as colleges by giving a higher grade of diploma when such colleges have existed without a practical university. These bodies were consequently specially singled out by me and mentioned as precedents. And I have their regulations actually by me and where they certainly do grant hoods. So, except for the consummate ease of criticism and *opposition which* is unworthy of attack, I hold that the Council of the Royal College of Surgeons had no justification whatever to issue its inappropriate *démenti*. At the time of the meeting, as now, I wished to suggest an improvement of the present *incomplete* academic dress of the College. If there are to be academicals at all they should have a hood attached, and not, as without the hood, liable to be mistaken by the public for the cloth garment of a verger or even that of the undergraduate status.—I am, Sir, yours faithfully,

Bognor, Feb. 8th, 1903. H. ELLIOT-BLAKE.

REMOVAL OF AN OPEN SAFETY-PIN FROM THE ŒSOPHAGUS OF AN INFANT.

To the Editor of THE LANCET.

SIR,—Dr. D. R. Paterson's case and comments in your issue of Feb. 1st are interesting and instructive. Certainly the most rational plan in removing foreign bodies from the food- and air-passages is that which removes them through the mouth by a skilful grasp and help from the eye. This plan, however, except in the most simple cases, must, in the nature of ordinary practice, be confined to specialists. I was interested in Dr. Paterson's article in the *British Medical Journal* on œsophagoscopy, but did not practise it, there being no instruments available. I shall, however, take his advice and attempt the experiment at the first opportunity. I am couples then becomes higher. Professor Senator has observed 516 married couples of whom either the husband or the wife, or both, were diabetic. The latter event happened in 18 instances (i.e., 3·5 per cent.), and taking only those couples who had been married from six months to one year the proportion rose to 4·1 per cent. Some of the cases were hereditary, but even 4·1 per cent. was not a proportion sufficiently high to make a communication likely. Some rather striking instances of communication have, however, been recorded, such as that of a washerwoman who had washed the linen of diabetic patients and that of a surgeon who had performed an amputation on a diabetic patient. Some pathologists have produced diabetes in animals by the inoculation of diabetic urine; experiments of this kind which Professor Senator had made were unsuccessful, but he nevertheless was of opinion that a communication of the disease might happen in certain favourable circumstances. In the discussion Dr. Neumann said that among 108 diabetic patients whom he had observed there was only one married couple. Dr. Albu said that he had found diabetes in two married couples, but in one of them the disease was hereditary and in the other it was caused by cancer of the pancreas. Professor Ewald said that in 120 cases he had not seen a single instance of *diabetes conjugalis*.

---

The Congress of Internal Medicine.

The Twenty-eighth Congress of Internal Medicine will meet this year in Vienna from April 6th to 9th, Professor Müller of Munich being in the chair. The official subjects of discussion will be as follows: (1) the Relations between the Genital Organs of Women and Internal Diseases, to be introduced by Professor von Rosthorn of Heidelberg and Dr. Lenhartz of Hamburg; and (2) New Methods of Examining the Function of the Intestines, to be introduced by Professor Schmidt of Halle. The other addresses the titles of which have been announced include one on the Present State of the Pathology and Treatment of Syphilis by Professor Neisser of Breslau and one on the Quantity and the Distribution of the Blood in Anæmia by Dr. Morawitz of Heidelberg. Visitors wishing to take part in the proceedings should make application to the general secretary, Dr. Pfeiffer of Wiesbaden.

Precocious Menstruation.

Professor Stoeltzner of Halle has described in the *Medicinische Klinik* the case of a child who began to menstruate when in her second year. She was two years and ten months old and had menstruated several times, the intervals being at first eight weeks and afterwards five weeks. She had well-developed mammæ and a large vulva. Her height was 102 centimetres and her weight was 19·5 kilogrammes, which corresponded to the weight of a child aged from five to six years. She was originally quite normal and at birth weighed 3·2 kilogrammes. She had her first tooth when six months old and could walk at the age of one year and two months. Precocious puberty has been described by some writers as a symptom of a morbid condition of other organs, such as malignant adenoma of a suprarenal gland or intracranial disease. In cases where precocious puberty was associated with menstruation a pathological condition of the ovaries was very likely to exist. Ovules were discharged as in normal menstruation and such children have been known to become pregnant. Children who presented this abnormality ought to be kept under observation, as malignant growths might develop in the ovaries.

The Serum Treatment of Scarlet Fever.

Dr. Pulawski of Radziejov, writing in the *Deutsche Medizinische Wochenschrift*, reports the results obtained in scarlet fever by the subcutaneous injection of serum which was produced by the inoculation of horses with streptococci cultivated from the blood of severe cases of scarlet fever. Of 35 severe cases treated with this serum 28 per cent. died, whereas of 28 severe cases treated without the serum 71 per cent. died. The serum proved to be quite innocuous and did not cause any undesirable symptom beyond a slight urticaria. Among the patients treated with serum there were ten deaths; these cases had, however, from the first been regarded as hopeless. In the remaining cases favourable action of the serum was shown by the rapid development and shortened duration of the exanthem, by mitigation of the grave symptoms, and by a quicker convalescence. It is probable that the serum protects the patients against complications such as otitis, lymphadenitis, and nephritis. In two cases complicated by diphtheria the joint administration of scarlet fever serum and diphtheria serum was useful.

Feb. 10th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

"La Ginecologia Moderna."

ITALIANS, according to Italy's greatest composer Rossini, owe a debt of gratitude to Spain, "which saves them from being ranked as the most backward of European nationalities." True in the main, the remark is specially true in medical literature, particularly medical journalism, in which all that can be said of Italy is that she is rather better than her Iberian sister. It is *pro tanto* the more gratifying, therefore, when a new accession to Italian periodicals is announced with the programme and the promise of *La Ginecologia Moderna* (*Modern Gynæcology*), the monthly review just started at Genoa under the competent editorship of Dr. Luigi Maria Bossi, professor of obstetrics and the propædeutics of gynæcology in that school. Not only does the new periodical deal with the medico-chirurgical questions to which the ailments of the female sex give birth, but it takes cognisance of the more general problems arising out of the psychological, the sociological, and the forensic aspects of that group of diseases. A novel feature of the journal will be the attention given to "female criminology," in which the phenomena of hysteria play a part becoming steadily more conspicuous from what a sociologist has called "the hyperæsthesia of our over-wrought civilisation." Among the contributors to the subject appear Dr. Cesare Lombroso of Turin and Professor Enrico Ferri of Rome. No reader of contemporary *causes célèbres* can fail to recognise in this department of *La Ginecologia Moderna* a most interesting field of observation and discussion.

Pharmaceutical Misadventure.

I had occasion recently to note the tragic consequences of the irregular prescription and administration of cod-liver oil with solution of phosphorus. Another case of misadventure is just reported from Codogno in the neighbourhood of Cremona, where a peasant woman was "treated" by a local pharmacist and died a few hours afterwards—a white powder (the nature of which has yet to be specified) having been given by mistake for magnesia. The pharmacist is now in prison and the matter, of course, *sub judice*. Meanwhile the case reinforces the warning addressed to all Italians (and others outside Italy) that, unless professionally prescribed and exhibited, medicines are fraught with danger—often death—to the consumer. I may add that Italian pharmacists are memorialising the Minister of Public Instruction (His Excellency Signor Rava), while maintaining the stringency of the gateway to the profession, to vouchsafe in consideration of the severe ordeal thus exacted the title of Doctor to the successful examinee. Certainly the claim is not an extravagant one, when the veterinary surgeon and the graduate in "zooiatria" can, after due examination, call himself "Doctor." The memorialists, however, do not strengthen their cause by the threat—all too common in Italian Universities—to refuse to attend the classes till their petition is granted. While at that end of the pharmaceutical ladder the aspirant is agitating for fuller rights, at the opposite end there is another movement much less to be encouraged—that is, to recognise as fully qualified for the practice of pharmacy those "assistants" who, without having passed an examination, have completed a certain number of years of apprenticeship. No doubt there are among these petitioners not a few highly expert and capable pharmacists, but to make all of them eligible for the rights which only the State diploma can confer would be to establish a dangerous precedent.

The National Institute of Physical Education.

True to the watchword of Cavour's successor, Massimo d'Azeglio, given forth just 40 years ago—"We have made Italy. Let us now make Italians"—the promoters of the physical rehabilitation of the "pubes Italica" are sparing no effort to diffuse and to intensify their salutary propaganda. At Rome in May next they will hold their first "Riunione," and the occasion will be signalised by the carrying out of a programme of gymnastic exercises, games, and other tests of physical development, agility, and strength, in which all the clubs of Italy, organised with that object, will be fully represented. Every facility will be offered to the public, domestic and foreign, to intervene at the "spettacolo"—railway transit being, for one thing, reduced 75 per cent. in cost to all who send in their names as intending visitors to the president, Signor Lucchini, Member of the Chamber of breeding-place near the abattoirs it was a very serious thing to consider whether the abattoirs should be allowed to exist in their present situation.

The Preservation of Infant Life.

The large number of inquests held in a year by the city coroner on children fatally burned has stimulated interest in the preservation of infant life in the city. The matter was brought before the health committee at its recent meeting by Mr. W. B. Stoddart, one of the city councillors (the well-known Cambridge cricketer). In response to the representations made by Mr. Stoddart for the better care of the children generous aid has been offered to the infant life preservation sub-committee of the health committee by two ladies—Mrs. Clayton of Wavertree and Miss Gladys O. Whitley of Sefton Park. The former has promised £200 and the latter £50 for the purpose of purchasing fire-guards for distribution amongst the poorest classes. The gifts were thankfully accepted by the health committee.

Death-rate of Liverpool.

Owing to the ravages of influenza and the rate of mortality among aged people the death-rate of the city for the past week was 33·7 per 1000, compared with 19·8 a year ago. The medical officer of health informed the health committee on Jan. 30th that the present outbreak of influenza was the most severe since 1895.

Medical Appointments at Birkenhead.

Dr. R. Owen Morris has been appointed medical officer of council schools and Mr. R. S. Marsden (medical officer of health of the borough) has been appointed superintendent medical officer of schools.

Toxteth Park Vaccination Statistics.

The vaccination officer of the Toxteth board of guardians has presented the board with the vaccination statistics for the year 1906 There were in the township 4140 births; 3142 of the infants were successfully vaccinated, 17 were "insusceptible," 6 were exempted on the conscience clause, 448 died before being vaccinated, 71 cases of vaccination were postponed by medical certificate, 441 could not be traced, and 15 infants were removed to other districts.

Presentations to a Medical Officer of Health.

During an interval in the proceedings of the Bootle council at a recent meeting Mr. T. W. N. Barlow, who was for six years medical officer of health of Bootle and who left last month to fill a similar post under the Wallasey district council, was the recipient of two handsome presentations. The mayor, on behalf of last year's health committee, presented him with an illuminated address expressing its appreciation of his efficient services and the town clerk handed him a gold watch from his late fellow officials. Mr. Barlow feelingly acknowledged both presentations in appropriate terms.

Feb. 11th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Housing in Swansea.

THE success of the proposed cottage exhibition to be held in Swansea in 1909 has been assured by the election of a representative committee to carry out the necessary details. Delegates from all the sanitary authorities in South Wales have been placed upon the committee together with the local Members of Parliament and others. A site owned by the Swansea corporation will probably be made use of and in other ways the corporation is assisting the enterprise. For many years past the question of providing suitable houses for the working-classes has been under serious consideration not only by the Swansea town council but by most of the local authorities in the neighbourhood. Private enterprise has to a certain extent been able to meet the demand for cottages in the borough of Swansea where plans for as many as 458 houses were approved by the corporation in 1906.

Medical Inspection of Schools.

The Newport (Mon.) education authority has decided to appoint an assistant medical officer for the purpose of carrying out the medical inspection of the children attending the public elementary schools. The salary proposed is £225 per annum with periodical increases to £275. A suggestion that the work might be done by the general practitioners of the town did not meet with the approval of the authority.—The Barry education authority has decided to appoint a medical officer at a salary of £250 per annum. He will work in conjunction with the medical officer of health. The question of appointing a whole-time medical officer of health for Barry has been under discussion but the arrangement indicated has been finally decided upon.—At a meeting of the Torquay town council held on Feb. 6th it was decided to appoint a medical officer to carry out the medical examination of school children at a salary of £150 per annum, increasing to £210.

Isolation Hospitals in North Wales.

Mr. J. O. Williams, medical officer of health of Barmouth, North Wales, has received an offer from Mrs. Talbot, Tynyffynon, to contribute £100 towards the cost of erecting an isolation hospital provided that five other similar sums are promised. The committee which is making arrangements for the provision of an isolation hospital has appointed deputations to wait on those who are likely to support the movement. The question of providing an isolation hospital in the adjoining town of Dolgelly has been again discussed by the urban council without coming to a definite issue. The council has already decided to build a small hospital which would be easy of extension if occasion arose, but the members are not unanimous as to the necessity for the expenditure.

Infant Mortality in Bristol.

In common with the rest of England and Wales there has been a considerable fall in the rate of infant mortality during the past few years in Bristol. In a report which the medical officer of health (Dr. D. S. Davies) has recently presented to the city health committee he expresses the hope that by the appointment of health visitors a still further reduction may be made. Dr. Davies very properly warns the committee that too much must not be expected of special work in this direction. In justification of this warning he gives a comparative chart and comparative table for Bristol and Huddersfield, from which, he says, it is evident that the wholesale improvement in the Huddersfield infant mortality returns claimed as due to the special measures taken there is not proved by the figures adduced to be due either entirely or in any large degree to these measures, for a practically identical improvement has taken place during the same years in Bristol without any special methods to this end having been taken. In the three years 1905–06–07 during which special work against infant mortality has been in progress in Huddersfield, the infant mortality rate in that town has been reduced 18 per cent., when compared with the rate of the preceding ten years. In Bristol the reduction has been 15 per cent. In Huddersfield during 1907 the rate was 97 per 1000 births, in Bristol 101, and in the whole country 118.

Milk-supply in Monmouthshire.

At a recent meeting of the Monmouthshire Chamber of Agriculture a resolution was passed asking that any legislation concerning the milk-supply should provide for uniform regulations throughout the country; that no vexatious restrictions calculated to render the production of milk more expensive should be adopted; and that the working of any new Act should be entrusted to the Board of Agriculture and Fisheries rather than to the Local Government Board. One of the speakers at the meeting deprecated what he called the milk scare, for which he said there were not sufficient grounds. A commentary upon these remarks is to be found in the report of the medical officer of health of the Llanelly rural district in which he stated that he could not recommend the registration of certain dairies and cowsheds, and with regard to other cowsheds in the district they were most of them left in such a filthy condition that it was not possible to enter them for inspection purposes.

Feb. 10th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh Royal Infirmary.

AT a meeting of the board of managers of this institution on Feb. 3rd Dr. Alexander Bruce and Mr. F. M. Caird were reappointed (the former as pathologist and resident physician and the latter as surgeon) for a further period of five years;

couples then becomes higher. Professor Senator has observed 516 married couples of whom either the husband or the wife, or both, were diabetic. The latter event happened in 18 instances (i.e., 3·5 per cent.), and taking only those couples who had been married from six months to one year the proportion rose to 4·1 per cent. Some of the cases were hereditary, but even 4·1 per cent. was not a proportion sufficiently high to make a communication likely. Some rather striking instances of communication have, however, been recorded, such as that of a washerwoman who had washed the linen of diabetic patients and that of a surgeon who had performed an amputation on a diabetic patient. Some pathologists have produced diabetes in animals by the inoculation of diabetic urine; experiments of this kind which Professor Senator had made were unsuccessful, but he nevertheless was of opinion that a communication of the disease might happen in certain favourable circumstances. In the discussion Dr. Neumann said that among 108 diabetic patients whom he had observed there was only one married couple. Dr. Albu said that he had found diabetes in two married couples, but in one of them the disease was hereditary and in the other it was caused by cancer of the pancreas. Professor Ewald said that in 120 cases he had not seen a single instance of diabetes conjugalis.

The Congress of Internal Medicine.

The Twenty-eighth Congress of Internal Medicine will meet this year in Vienna from April 6th to 9th, Professor Müller of Munich being in the chair. The official subjects of discussion will be as follows: (1) the Relations between the Genital Organs of Women and Internal Diseases, to be introduced by Professor von Rosthorn of Heidelberg and Dr. Lenhartz of Hamburg; and (2) New Methods of Examining the Function of the Intestines, to be introduced by Professor Schmidt of Halle. The other addresses the titles of which have been announced include one on the Present State of the Pathology and Treatment of Syphilis by Professor Neisser of Breslau and one on the Quantity and the Distribution of the Blood in Anæmia by Dr. Morawitz of Heidelberg. Visitors wishing to take part in the proceedings should make application to the general secretary, Dr. Pfeiffer of Wiesbaden.

Precocious Menstruation.

Professor Stoeltzner of Halle has described in the *Medicinische Klinik* the case of a child who began to menstruate when in her second year. She was two years and ten months old and had menstruated several times, the intervals being at first eight weeks and afterwards five weeks. She had well-developed mammæ and a large vulva. Her height was 102 centimetres and her weight was 19·5 kilogrammes, which corresponded to the weight of a child aged from five to six years. She was originally quite normal and at birth weighed 3·2 kilogrammes. She had her first tooth when six months old and could walk at the age of one year and two months. Precocious puberty has been described by some writers as a symptom of a morbid condition of other organs, such as malignant adenoma of a suprarenal gland or intracranial disease. Another case of misadventure is just reported from Codogno in the neighbourhood of Cremona, where a peasant woman was "treated" by a local pharmacist and died a few hours afterwards—a white powder (the nature of which has yet to be specified) having been given by mistake for magnesia. The pharmacist is now in prison and the matter, of course, *sub judice*. Meanwhile the case reinforces the warning addressed to all Italians (and others outside Italy) that, unless professionally prescribed and exhibited, medicines are fraught with danger—often death—to the consumer. I may add that Italian pharmacists are memorialising the Minister of Public Instruction (His Excellency Signor Rava), while maintaining the stringency of the gateway to the profession, to vouchsafe in consideration of the severe ordeal thus exacted the title of Doctor to the successful examinee. Certainly the claim is not an extravagant one, when the veterinary surgeon and the graduate in "zooiatria" can, after due examination, call himself "Doctor." The memorialists, however, do not strengthen their cause by the threat—all too common in Italian Universities—to refuse to attend the classes till their petition is granted. While at that end of the pharmaceutical ladder the aspirant is agitating for fuller rights, at the opposite end there is another movement much less to be encouraged—that is, to recognise as fully qualified for the practice of pharmacy those "assistants" who, without having passed an examination, have completed a certain number of years of apprenticeship. No doubt there are among these petitioners not a few highly expert and capable pharmacists, but to make all of them eligible for the rights which only the State diploma can confer would be to establish a dangerous precedent.

The National Institute of Physical Education.

True to the watchword of Cavour's successor, Massimo d'Azeglio, given forth just 40 years ago—"We have made Italy. Let us now make Italians"—the promoters of the physical rehabilitation of the "pubes Italica" are sparing no effort to diffuse and to intensify their salutary propaganda. At Rome in May next they will hold their first "Riunione," and the occasion will be signalised by the carrying out of a programme of gymnastic exercises, games, and other tests of physical development, agility, and strength, in which all the clubs of Italy, organised with that object, will be fully represented. Every facility will be offered to the public, domestic and foreign, to intervene at the "spettacolo"—railway transit being, for one thing, reduced 75 per cent. in cost to all who send in their names as intending visitors to the president, Signor Lucchini, Member of the Chamber of

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Emigration from Ireland.

IT is deplorable to record that during the first month of this year 641 people (378 males and 263 females) emigrated from Ireland. Of the total, 360 were from Ulster (showing a decrease of 32 as compared with the same month last year), 131 from Leinster (a decrease of 38), 117 from Munster (an increase of 16), and 33 from Connaught (an increase of 2). The destinations of these emigrants were as follows: 256 went to the United States, 272 to Great Britain, 48 to Canada, 37 to Australia, 11 to South Africa, 6 to New Zealand, and 11 to other countries. The steerage passengers to the United States numbered 219, of whom 44 had their passages paid in America. The public health conditions of Ireland certainly play their part in this progressive depopulation of the country, a fact which should be borne in mind by those who too readily attribute every ill in Ireland to political troubles.

Opening of the Tuberculosis Exhibition at Banbridge.
